Disazo Colouring Matters and Tetrazo Colouring Matters
Zeits. f. angew. Chem. 1889, 50—52.

THE sulphonic-compounds of amidophenols combine with α -naphthylamine and form compounds of the general formula—

These bodies being again diazotised and coupled with alpha- and beta-naphthol-sulphonic acids produce colouring matters showing great fastness to light on the fibre.

To prepare these bodies 21.5 kilos. of sodium amido-*p*-phenol sulphonate are diazotised with 7 kilos. of sodium nitrite, hydrochloric acid being added to the mixture of these two compounds. Then 20 kilos. of naphthylamine hydrochloride are added, and after a short time the new compound, $C_{10}H_7(OH)(SO_3H)N=N \cdot C_{10}H_7NH_2$, separates from the solution. At ordinary temperatures the combination

is finished in several days; but it can be accelerated by warming from 40°–50° C. As soon as a sample, after filtration and some standing, does not produce any more colouring matter, the dark green precipitate is filtered and washed. It dissolves in sulphuric acid with a dark violet, in ammonia with a brown-orange colour. The precipitate is dissolved in 10 kilos. of ammonia of 17 per cent., and to this solution 7 kilos. of ammonia are added. The mixture is poured into hydrochloric acid which is cooled with ice. The diazo-compound thus formed has a pure brown colour and is treated with 38 kilos. of R. salt. The colouring matter obtained, forms a black precipitate. It dissolves in sulphuric acid with a blue colour, and dyes wool violet to violet-black. Similar dye-stuffs are obtained from amidophenol sulphonic acid, α -naphthylamine, and Schäffer's beta- and alpha-(Neville and Winter's) naphtholsulphonic acid, and from amido-ortho-cresol- and amido-para-cresol-sulphonic acids. The following table shows the reactions of the cresol derivatives:—

Properties.	Colouring Matters from Amido-ortho-cresolsulphonic Acid with			Colouring Matters from Amido-para-cresolsulphonic Acid with

PATENTS.

Improvements in the Manufacture of Colouring Matters.
H. H. Leigh, London. From R. G. Williams, Albany, U.S.A. Eng. Pat. 1593, February 2, 1888. 6d.

PHENYLENE diamine and its homologues when diazotised and combined with resorcinol, α -naphthol, the phenols, benzoic and the hydroxy-benzoic acids and their substitution products, forms colouring matters soluble in alkalis, but insoluble in dilute acids; when combined with aniline and its homologues, β -naphthol, the naphthylamines and their substitution products, the colouring matters formed are insoluble both in alkalis and dilute acids. On combining it, however, with the sulphonic acids of amines, amides and phenols, the colouring matters produced are very soluble in dilute alkalis, and are also partially soluble in water. The following example illustrates the method of applying the invention: 10.8 lb. of phenylenediamine or the equivalent weight of one of its homologues are dissolved in 180 lb. of water and 70 lb. of hydrochloric acid of 22° B. After cooling the solution to -10° a solution of 14 lb. of nitrite of soda in 70 lb. of water are slowly added, the temperature not being allowed to rise. A clear reddish-brown solution results, which is run into 22 lb. of resorcinol, and 120 lb. of sodium acetate dissolved in 1,000 lb. of water. A brown colouring matter is at once precipitated, and the reaction is completed when all the free mineral acid is taken up. After filtering and purifying in the usual manner, the colouring matter is obtained in the form of a reddish-brown powder, insoluble in dilute acids or water, but soluble in alkalis.

—T. A. L.

Improvements in the Manufacture of Colouring Substances by the Reaction of Aromatic Hydrazine Sulphonic Acids on Retenequinone. W. P. Thompson, Liverpool. From The Actiengesellschaft für Chemische Industrie Rheinau, Germany. Eng. Pat. 4217, March 19, 1888. 6d.

It has not hitherto been possible to condense retenequinone with the aromatic hydrazines. Condensation, however, takes place when sulphonic acids of the latter are used. These are obtained by reducing the diazo-compounds of amido-sulphonic acids with stannous chloride or sodium sulphite. The hydrazines of the following compounds all form colouring matters when condensed with retenequinone. Sulphanilic acid, *m*-amido-benzene sulphonic acid, *o*-toluidine-*p*-sulphonic acid, *p*-toluidine-*o*-sulphonic acid, xylylidine sulphonic acid (from commercial *m*-xylylidine), cumidine sulphonic acid (from pseudocumidine), α -naphthylamine sulphonic acid, β -naphthylamine sulphonic acid (Ger. Pat. 22,547), β -naphthylamine- δ -sulphonic acid, benzidine disulphonic acid, and benzidine-sulphonic disulphonic acid. The method employed is as follows: 26.4 kilos. (1 mol.) of retenequinone and 37.6 kilos. (2 mol.) of phenylhydrazine sulphonic acid, are boiled in a sufficient quantity of water until a clear red liquor results. This is then neutralised with soda and the colouring matter salted out. The shades obtained with the different sulphonic acids vary from orange-red to bluish-red, and are fast to soap. Both wool and silk completely exhaust the dye-bath.—T. A. L.

Improvements in the Manufacture of Nitroso Compounds, and of Colouring Matters therefrom suitable for Dyeing and Printing. T. Y. Johnson, London. From The Badische Anilin und Soda Fabrik, Ludwigshafen-on-the-Rhine, Germany. Eng. Pat. 4476, March 23, 1888. 6d.

Basic colouring matters are formed by condensing α -naphthylamine and its secondary or tertiary alkyl derivatives with the nitroso compounds of dimethyl and diethyl *m*-amido phenols. The latter are formed by dissolving the dimethyl or ethyl *m*-amido phenol in three times its weight of strong hydrochloric acid, cooling to 0° and adding .53 or .44 parts respectively of 96 per cent. sodium nitrite in about twice its weight of water, care being taken to keep the temperature at 0°. The nitroso compound separates as the hydrochloride in the form of a yellow crystalline substance soluble in water. The base can be obtained by careful neutralisation with an alkali and extraction with benzene or chloroform. The following is an example of the method employed for obtaining blue colouring matters. α -Naphthylamine hydrochloride is mixed with four times its weight of glacial acetic acid, and twice its weight of water. This mixture is heated to 60° in an enamelled pan, and one part of the nitroso-diethyl-*m*-amido phenol hydrochloride is gradually added under constant stirring. The temperature is then raised to 100° until the blue colour does not increase in intensity, when the melt is cooled to 30°, and mixed with two parts by weight of water which precipitates the colouring matter. To render it soluble it is converted into a sulphonie acid by dissolving it in eight times its weight of warm concentrated sulphuric acid, and pouring the mixture into the same weight of water, after which it is filtered, washed with sodium sulphate solution, pressed and dried. The colouring matter obtained from ethyl- α -naphthylamine requires to be salted out by means of chloride of zinc and salt. The colouring matters produced as above are basic, and dye animal fibres directly in a neutral or slightly acid bath. Vegetable fibres require a tannin mordant. The shades produced are similar to those of methylene blue.—T. A. L.

The Manufacture of a New α -Naphthol Disulphonic Acid. C. D. Abel, London. From The Actiengesellschaft für Anilin Fabrikation, Berlin, Germany. Eng. Pat. 4625, March 26, 1888. 6d.

WHEN naphthalene is treated with fuming sulphuric acid below 100°, and subsequently with nitric acid, two nitro-naphthalene disulphonic acids are formed, which, on reduction, yield amido acids, whose sodium salts differ in solubility. The less soluble one corresponds to the α -naphthol disulphonic acid of Ger. Pat. 40,571, and the solution when filtered yields crystals of a new amido-naphthalene disulphonic acid when hydrochloric acid is added. 20 kilos. of naphthalene are dissolved in 100 kilos. of fuming sulphuric acid containing 23 per cent. of sulphuric anhydride at a temperature not exceeding 60°. 14 kilos. of nitric acid of 45 B. are then added at a temperature below 40°, and under constant agitation. When the reaction is complete the melt is dissolved in water, limed, and the filtered solution concentrated. The nitro-naphthalene disulphonic acids are then reduced with iron and sulphuric acid, and converted into the calcium salts by boiling with milk of lime. The filtered solution is decomposed with sodium carbonate, and, after filtering, the solution of the sodium salts of the amido-naphthalene disulphonic acids is evaporated to crystallisation. The filtrate on treatment with an excess of hydrochloric acid yields crystals of the acid sodium salt of a new amido-naphthalene disulphonic acid, which is purified by crystallising it from five parts of boiling water, when it separates in long white needles having the composition—

When distilled with lime α -naphthylamine is produced. Its diazo-compound precipitates in colourless needles and is decomposed by boiling with water, acidified with sulphuric acid, into the new α -naphthol disulphonic acid, of which the sodium salt crystallises in long colourless

needles. The new acid differs from that described in the Ger. Pat. 40,571 by not forming "Brilliant yellow" when treated with nitric acid. By acting on it with the diazo-compounds of diphenyl, ditolyl, stilbene, &c., blue dye-stuffs are formed which dye unmordanted cotton from a soap-bath.—T. A. L.

Improvements in Colour Mixers. A. F. Wenger, Hanley. Eng. Pat. 5234, April 9, 1888. 8d.

THE vessel containing the colouring matter is basin-shaped, open at the top, and turns on trunnions near its base, so that it may be swung over and emptied when necessary; at the bottom may be a steam space for heating its contents. In it is a pear-shaped muller revolving about an axis inclined at about 45° to the horizontal, and having motion communicated to it by means of a pair of bevel cogs from a short shaft bearing a fast and loose pulley, the whole of this arrangement is carried by a frame working on trunnions, so that the muller may be lifted out of the basin when requisite. To facilitate this, from one side of the frame springs a lever carrying a counterweight, sliding upon it, and capable of being fixed at any point by means of a set screw; this lever is hinged at the point where it joins the frame, so that it can be moved over until it is on the same side of its fulcrum as the muller, thereby increasing the pressure on the latter. The muller is provided on its upper side with an adjustable scraper parallel to its surface, which removes any colouring matter clinging to it, and prevents it creeping on to the axle.—B. B.

Improvements in the Manufacture of Colouring Matters. H. H. Leigh, London. From R. G. Williams, Albany, U.S.A. Eng. Pat. 5404, April 11, 1888. 4d.

RED and bluish red colouring matters which dye unmordanted cotton from a soap-bath are formed by the action of tetrazo-diphenyl and its homologues and sulphonie acids on dihydroxytoluene, its homologues, substitution products, and sulphonie acids. 28 lb. of benzidine sulphate suspended in 200 lb. of water and 25 lb. of hydrochloric acid, 22° B., are diazotised at a low temperature with 14 lb. of sodium nitrite in 70 lb. of water, and the solution is then added to 28.4 lb. of orcinol, 100 lb. of sodium acetate, and 10 lb. of caustic soda dissolved in 100 gallons of water. The brown precipitate formed after 15 hours is filtered off, washed, and dried.—T. A. L.

New Blue Colouring Matters and in the Manufacture of the same. S. Pitt, Sutton. From Leopold Casella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 5852, April 19, 1888. 4d.

THE *p*-nitroso derivatives of secondary and tertiary amines combine with diphenyl-*m*-phenylenediamine, or its homologues, with the formation of blue colouring matters. 2 parts by weight of nitrosodimethylaniline hydrochloride are heated in alcohol or other solvent with 1 part of diphenyl-*m*-phenylenediamine, or a corresponding amount of one of its homologues. When the reaction is complete the melt is diluted with water, filtered, and the colouring matter salted out. The dye-stuff is more violet if less of the nitroso compound be used. It dissolves in strong sulphuric acid with a black shade, and dyes wool, silk, and mordanted cotton a dark blue, which is fast to washing.

—T. A. L.

Manufacture of Blue Colouring Matters. C. D. Abel, London. From The Actiengesellschaft für Anilin Fabrikation, Berlin, Germany. Eng. Pat. 5909, April 20, 1888. 6d.

BENZIDINE, tolidine, diamido-stilbene, and the methyl, or ethyl ether, of diamido-diphenol, when diazotised and combined with α -naphthol disulphonic acid (Eng. Pat. 4625 of 1888, see above), gives rise to blue colouring matters, which dye unmordanted cotton more evenly and stronger than those at present on the market. A bluish-violet dye-stuff is obtained in the following manner:—

21 kilos. of diamido-stilbene are dissolved in 58 kilos. of hydrochloric acid and 1,000 litres of water, diazotised by means of 14 kilos. of sodium nitrite in 50 litres of water, and added to a solution of 35 kilos. of sodium α -naphthol disulphonate, and 41 kilos. of sodium acetate in 1,000 litres of water. The intermediate compound thus formed is again combined with an alkaline solution of 35 kilos. of α -naphthol-disulphonic acid. The mixture is allowed to stand for some hours, then heated, and the colouring matter formed is salted out, filter-pressed, and dried. The second molecule of the sodium α -naphthol-disulphonate in the above example may be replaced by salts of α - and β -naphthol, their mono- and disulphonic acids with the formation of similar bluish-violet dye-stuffs. The diamido-stilbene may also be replaced by an equivalent quantity of its sulphonic acid, of benzidine, *o*-tolidine, dianisidine, or diphenetidine—

The colouring matter from dianisidine dyes a very green shade of blue.—T. A. L.

Manufacture of Azo Colouring Matters. C. D. Abel, London. From The Actiengesellschaft für Anilin Fabrikation, Berlin, Germany. Eng. Pat. 5910, April 20, 1888. 6d.

By combining the new α -naphthol disulphonic acid (Eng. Pat. 4625 of 1888, see previous page) with diazo compounds, colouring matters are obtained which dye red, brown, violet, and bluish-black. 15.75 kilos. of xylylene hydrochloride are dissolved in 100 litres of water and 12 kilos. of hydrochloric acid, and diazotised with 6.9 kilos. of sodium nitrite in 50 litres of water. The diazo solution is poured into 700 kilos. of water containing 34.8 kilos. of the sodium salt of the new α -naphthol disulphonic acid, the solution being kept alkaline with sodium carbonate until the reaction is complete. The dye-stuff formed is salted out, pressed, and dried. It dyes wool yellowish red from an acid bath. The following are the various shades obtained from different amines and their sulphonic acids:—Camidine dyes red; α -naphthylamine, brown; β -naphthylamine, red-brown; amido azo-benzene or toluene dye brown; naphthionic acid dyes brown red; β -naphthylamine- β -sulphonic acid, red; sulphamic acid azo- α -naphthylamine, brown; β -naphthylamine- α -sulphonic acid-azo- α -naphthylamine, brown; α -naphthylamine disulphonic acid-azo- α -naphthylamine, red-violet; and β -naphthylamine disulphonic acid G-azo- α -naphthylamine, bluish-black.—T. A. L.

Improvements in the Manufacture of Colouring Matters. H. H. Leigh, London, From R. G. Williams, Albany, U.S.A. Eng. Pat. 6743, May 5, 1888. 6d.

This is an extension of Eng. Pat. 5104 of 1888 (page 280), and provides for the production of colouring matters by combining one molecule of tetrazo-diphenyl, its homologues and substitution products, with one molecule of dihydroxy-toluene, its homologues or substitution products, and afterwards with another molecule of a different dihydroxy derivative or substitution product of toluene or its homologues. The colouring matters as above dye unmodified cotton in an alkaline-bath, and the colours are fast to soap.

—T. A. L.

Improved Process or Method for effecting the Separation of Isomeric Xylidines from Commercial Xylidine in a Pure State for the Production of Colouring Matters. L. Limpach, Manchester. Eng. Pat. 6899, May 9, 1888. 6d.

The method depends upon the fact that when crude xylidine is treated with acetic acid only *m*-xylidine ($\text{CH}_3:\text{C}_6\text{H}_4:\text{NH}_2 = 1:3:4$) forms a solid acetyl compound. The following example is given to show the method employed: 121 grms. of commercial xylidine are treated with 30 grms. of 100 per cent. acetic acid and allowed to stand for 24 hours. Crystals separate out which consist of pure *m*-xylidine acetate which can be converted into the base by known methods.

The mother liquors are treated with hydrochloric acid, and after standing 3–4 days about 20–25 per cent. of *p*-xylidine separates out as hydrochloride. The filtrate from this contains principally derivatives of *o*-xylidine.—T. A. L.

Improvements in the Process for the Manufacture of Azo Colouring Matters. H. H. Leigh, London, From R. G. Williams, Albany, U.S.A. Eng. Pat. 15,654, October 30, 1888. 6d.

TETRAZO-DIPHENYL or one of its homologues is combined with two molecules of "a sulpho acid of diazo-amido-benzene" or its homologues* and two molecules of an amine or a phenol are then substituted for the two molecules of the "diazo-amido-benzene sulpho-acid" employed. The following are the amines employed: aniline, its alkyl derivatives, homologues and sulphonic acids, the naphthylamines and their sulphonic acids. The phenols mentioned are: phenol and cresol, the naphthols, resorcinol, orcinol, dioxy-naphthalene and sulphonic acids of all the preceding. It is to be noted that the colours obtained by this method are identical with those described in Eng. Pat. 6687 of 1887 (this Journal, 1888, 430), which claims the combination of tetrazo-diphenyl and its homologues with the sulphonic acids of amido azo-benzene, and subsequent replacement of these latter by amines and phenols. The following examples are given in the present invention. To obtain Congo-red, 28 lb. of benzidine sulphate are diazotised and the solution is run into 60 lb. of the sodium salt of the "sulpho-acid of diazo-amido-benzene," and 60 lb. of sodium acetate dissolved in 50 gallons of water. The compound separates as a brown flocculent precipitate, and is kept stirred for 12 hours. It is then run into a solution of 55 lb. of sodium naphthionate and 60 lb. of sodium acetate dissolved in 200 gallons of water with constant stirring, which is continued for 12 hours. The colour is then filtered off "and converted into its soda salt." If in the above example 31.2 lb. of tolidine sulphate be employed in place of the benzidine, the colour known as Benzopurpurin is obtained. Congo 4 R. is obtained in a similar manner by using tolidine and replacing one of the two molecules of sodium naphthionate by one molecule of resorcinol.—T. A. L.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

PATENTS.

Improvements in Immersion Rollers used in Printing, Dyeing, Bleaching, Sizing, or other like Purposes. T. Winter, Blackburn. Eng. Pat. 1357, January 30, 1888. 8d.

IMMERSION rollers constructed as heretofore have a solid core or centre, or solid core with corrugated circumference. In this invention the solid core is dispensed with. End pieces or flanges have secured to them a series of laths or strips of copper, brass, or other metal placed so as to radiate from a common centre. These laths are strengthened by supports placed at intervals of their length. The warps or other material under operation are wound on the outside edge of the laths so that the dye or size is better able to permeate through the material than when wound on solid rollers.—W. E. K.

Improvements relating to the Washing or Scouring and Felling of Cloth and similar Materials. F. F. and M. L. Rohart, Paris, France. Eng. Pat. 1464, January 31, 1888. 6d.

THE fatty or greasy matters contained in woollen and similar stuffs are rendered saponifiable by treatment with alkaline hydrosulphides; the hydrosulphide is decomposed, the sulphur combining with the fatty matter, and the base

* The preparation of this body is not described in the patent.

dissolving the compound so obtained. In the case of cloth the operation takes place in the fulling machine. The piece is washed with pure water, left to dry for about 24 hours, then introduced into the fulling machine, into which the hydrosulphide is admitted in a thin jet. The formation of soap is almost instantaneous: one or two kilos. of hydrosulphide at 20° B., diluted to 2°—3° B., is sufficient for each piece of 30 metres. Sometimes it is necessary to add a certain proportion of olein to the fulling machine, preferably before the hydrosulphide is admitted. The cloth should be frequently "tried," and the addition of olein, hydrosulphide and water regulated according to circumstances; if the piece be too greasy, hydrosulphide is to be added, or olein if not sufficiently greasy, water being admitted when the soap is in too thick a paste or the cloth too dry.

After this operation the cloth is rinsed in water and soaked in a solution of carbonate of soda, the strength of which varies according to the more or less greasy state of the cloth; finally it is well washed in flowing water. Either monosulphides or polysulphides may be used, provided they be saturated with sulphuretted hydrogen, and the process is applicable to the washing of greasy wool and the scouring of woollen thread or fabric as well as in the fulling of woollen stuffs.—E. B.

Improvements in Apparatus for Washing, Cleansing, Dyeing or Steeping Fabrics and other like Purposes. W. P. Thompson, Liverpool. From A. Douleuron and E. van Meerbeeck, Ixelles-lez-Bruxelles, Belgium. Eng. Pat. 3232, March 2, 1888. *8d.*

The apparatus consists of a revolving perforated drum, made of copper or other material, which contains the clothes or fabrics to be washed, cleansed, dyed, &c. The lower part of this drum rotates in a pan or receptacle, preferably covered in, containing the washing or other liquid, and the remainder of the pan, not filled with liquid, is filled with steam or vapour. The pan is heated by a fire placed underneath. The form of the drum is cylindrical in cross section about the middle of its length, but its ends are closed by truncated cones. Besides the use for domestic purposes, it is stated the apparatus can find useful application in connexion with bleaching, dyeing, tanning, hat-making, glove-making, leather dressing, &c. A drawing is given.—E. B.

Improvements in Dyeing Apparatus. W. Mycock, Stockport. Eng. Pat. 3490, March 7, 1888. *8d.*

This invention relates to the dyeing of fabrics which have to be immersed successively in a number of dye-vats, and in particular to indigo dyeing of cloths printed with resist pastes, an operation usually performed by hand. The vats are, by preference, arranged as usual side by side in line, but this order may be varied. The cloth is fixed in rectangular hooking frames in the usual way. Extending over the row of vats is a carriage movable on girders and fitted with lifting appliances for raising or lowering a dip-frame, to or from which the cloth frames can be attached or detached by means of self-acting catches. By this arrangement the series of frames can be lifted, the cloth held in the air for the time requisite for the oxidation of the indigo, and the carriage then run forward and the frames dropped into the next succeeding vats. After the cloth frames have been immersed they are unhooked from the carriage and the latter is run back ready for the next lift of cloth frames.—W. E. K.

Improvements in Machinery or Apparatus for Washing or Cleansing Wool or other Fibrous Materials. J. and E. W. Petrie, Rochdale. Eng. Pat. 4786, March 29, 1888. *8d.*

The improvements relate to the mechanism in use for the transfer of the washed wool from the trough, where it has been cleansed, to the squeezing rollers, as described in Eng.

Pats. 43 of 1874 and 4261 of 1880, and also to the method of conveying wool from the trough to the squeezing rollers when these are placed in proximity to the trough, not being submerged in the same, but with the bottom roller placed below or partially below the level of the water-line in the trough. The improvements dispense with the fixed grid and its support, and the upper vibrating rake, described in Eng. Pat. 43 of 1874, and replace these appliances with a vibrating rake armed with one or more rows of prongs, by which the wool is conveyed to the fall plate and thence to the squeezing rollers. This vibrating delivery rake may be combined with the ordinary swing or vibrating rake and actuated by similar mechanical arrangement. In the case where the squeezing rollers are placed above or proximately above the water-line in the washing trough, the double-headed rake described in Eng. Pat. 4261 of 1880 is replaced by a single adjustable vibrating rake held by a jointed radial rod with a check or stop motion at the point of delivery, more effectually delivering the wool on to the slide bars or other travelling appliances used for conveying the same to the squeezing rollers. A drawing is given.—E. B.

A Composite Indigo Dye. La Société L. Durand, Huguenin et Cie., Bâle, Switzerland. Eng. Pat. 15,496, October 27, 1888. *4d.*

This invention describes the employment of indopheno ($C_{18}H_{16}N_2O$) (Eng. Pat. 1373, 1881) as a diluent for indigo thereby effecting a considerable saving in cost and time without impairing the fastness of the colour. The method employed is as follows:—1 kilo. of dry powdered indophenol is mixed with 100 litres of water, 10 kilos. of indigo paste (containing 20 per cent. of dry indigo), 10 litres of sodium bisulphite of 39° to 40° B., 2 kilos. of stannous chloride, and 2,500 kilos. of zinc powder. The mixture is agitated for an hour and is then treated with 8 litres of caustic soda of 38° B. It is again agitated, and on the following day diluted with twice its volume of cold water. After vigorous agitation it is allowed to stand until clear and may then be used for dyeing in the ordinary manner. The colour of the goods is increased 10 to 15 per cent. by passing them immediately after dyeing through a $\frac{1}{4}$ per cent. solution of potassium bichromate. Indophenol, when treated by itself in the above manner, is only reduced with difficulty and dyes a violet-blue colour which fades to a greyish-violet, and is only moderately fast. The composite dye, however, behaves exactly like indigo and resists moreover, better than indigo itself, the action of discolouring agents. (See also this Journal, 1889, 189.)—T. A. L.

Improvements in the Method of and in Apparatus for Dyeing, Scouring, or Washing Wool and other Materials. F. E. Anderson, New Jersey, and S. Hodgson, Mass., U.S.A. Eng. Pat. 17,271, November 27, 1888. *8d.*

This method of dyeing, &c. cannot be properly understood without reference to the drawings. The "staple" is submerged and subjected to the intermittent action of the liquids used, the material receiving, at the same time, a forward impulse. A receiving hopper, containing a toothed drum and flushing mechanism, is connected with a tube having an upturned delivery end; the tube gradually increases in diameter from the hopper to the delivery end. Twenty-two claims are made.—E. B.

Improvements in Hollow Perforated Tubes for Dyeing, Bleaching, or otherwise Treating Yarns in Cops. H. F. Lippitt, Providence, U.S.A. Eng. Pat. 18,317, December 18, 1888. *8d.*

This invention, which relates to the dyeing, &c. of yarn in cops by forcing or sucking liquids through the cops when mounted on hollow spindles, is an improvement on Graemiger's U.S. Pat. 368,715 of 1887. The improvement consists in narrowing or contracting the spindle in that portion of its length which is adjacent to the thickest portion of the cop, for the purpose of permitting a readier

passage of liquid where the cop is least readily traversed by the bleaching or dyeing liquor. The hollow spindle is closed at its upper end, has perforations in its wall for the passage of the liquid used, and at its lower end is an annular flange on which the cop rests. Drawings are given.

—W. E. K.

A new Mordant for Dyeing Purposes. E. O. Fankhauser, Burgdorf, Switzerland. Eng. Pat. 18,717, December 21, 1888. 4d.

This invention relates to a mordant termed "Fankhausine" by aid of which cotton and other fibres can be dyed direct "without requiring previous boiling." For its preparation 100 parts of castor oil are treated with 20 parts of sulphuric acid and neutralised with soda. Next, 7 parts of sumac extract are boiled with 20 parts of "olein soap" and, when cold, well stirred into the castor oil preparation. It is claimed that cotton or mixed fibres, when mordanted with this "sumac-oil-soap," takes up dye-stuffs readily.—W. E. K.

Improvements in Machinery for or connected with the Dyeing of Textile Matters in Skeins. P. Haddan, London. From E. Six-Serve, Tourneing, France. Eng. Pat. 18,776, December 22, 1888. 8d.

This specification does not admit of suitable abstraction. It describes an apparatus for supporting the skeins of yarn, immersing them in the dye-vessel, and constantly turning them during the operation of dyeing. The details are illustrated in eight drawings.—W. E. K.

VII.—ACIDS, ALKALIS, AND SALTS.

Notes on the Reactions in the Sulphuric Acid Chambers. A. Schertel. Chem. Ind. 12, 80—81.

LUNGE and NAEF found some time ago (this Journal, 1884, 258), that the oxidation of sulphurous acid is very energetic as far as the middle of the first chamber, after which it rapidly decreases. The percentage of sulphurous acid in the gases of the second half of a chamber is nearly the same throughout. When the gases pass from one into the next chamber, an energetic reaction sets in again, which diminishes as soon as the gases pass into the second half of the chamber. Schertel's observations confirm Lunge and Naef's results, but he does not consider their explanation satisfactory. He thinks that the mist of nitrososulphonic acid in the second half of the chamber remains undecomposed owing to want of steam, and consequently there is a scarcity of nitrous acid in the gases. When these enter the next chamber, the fresh steam introduced brings about the decomposition of the nitrososulphonic acid, accompanied by a liberation of nitrous acid, which latter is the cause of the renewed activity. Gradually a mist of nitrososulphonic acid is again formed, and thereby a partial suspension of the reaction. It is well known in practice that the oxidation of sulphurous acid is greatly accelerated by an increased admission of steam, and direct gas tests bear out the practical experience. Nitrososulphonic acid is a much more stable compound than is generally supposed, and requires a good deal of steam for its decomposition.

A portion of the gases, as they passed from the first into the second chamber, was passed into a long pipe filled with coke, and was allowed to traverse the pipe for several weeks. When the pipe was opened well-shaped crystals of nitrososulphonic acid were found on that side of the coke which faced the current of the gases. During the time of the experiment the acid formed in the pipe had a specific gravity of 1.49. This interesting phenomenon is quite compatible with Schertel's explanation given above, and it is perhaps possible to base on it a method for accelerating the sulphuric acid reactions.—S. H.

Ammonium Salts in Stassfurt Carnallite. W. Diehl. Chem. Zeit. 13, 64.

By distilling carnallite with sodium hydrate a quantity of ammonia was found in the distillate equal to 0.01—0.015 per cent. of ammonium chloride.—J. W. L.

Change of Rotation of Tartaric Acid in Mixed Solutions. R. Pribram. Ber. 22, 6—11.

OPTICALLY inactive substances alter the amount of rotation of tartaric acid, in some cases annihilating it entirely or even producing an opposite rotation. The aromatic hydrocarbons have a special influence in this direction. Thus a solution of 2 grms. of tartaric acid in 40 cc. of ethyl alcohol turns the plane of polarisation $\alpha_D^{20} = +37.9$. If a solution in 20 cc. of alcohol and 20 cc. of benzene be used the rotation becomes -41.1 . In the case of the higher homologues of benzene the effect is still more marked. The halogen substitution products increase the left-handed rotation, the nitro-substitution products have an opposite effect. The amido-group increases the rotation of tartaric acid. This is shown by experiments on urea and aniline. In the case of pyridine the effect reaches a maximum when about 50 per cent. of pyridine is present. It then decreases proportionately with the amount of pyridine in solution.—J. B. C.

Nitrogen Pentoxide. L. Meyer. Ber. 22, 23—24.

NITRIC anhydride prepared by distilling strong nitric acid with strong sulphuric acid mixes with phosphorus pentoxide without perceptible rise of temperature. This agrees with Thomsen's observation that P_2O_5 dissolves in water with 36,000 cals., whereas N_2O_5 dissolves with about 30,000 cals. According to Berthelot nitrogen pentoxide gives with benzene at 55° C. dinitrobenzene, and a solution of benzene and N_2O_5 in sulphuric acid yields dinitrobenzene at 160°.

—J. B. C.

Formation of Carbonyl Sulphide. C. Böttinger. Ber. 22, 306.

THE author finds that carbonyl sulphide is formed by heating a mixture of carbon and ultramarine, and the formation of this compound by analogy with the action of carbon bisulphide upon clay (see this Journal, 1889, 118) is probably due to the intermediate production of carbon bisulphide.—J. B. C.

A New Potassium Ferrocyanide Compound. F. Mahla. Ber. 22, 111—117.

THE liquor obtained by extracting the product from the gas-purifiers with water yields with ferric chloride a precipitate of Prussian blue, if after filtration a further addition of ferric chloride gives a violet precipitate, which is decomposed with caustic potash, forming a precipitate of ferric oxide. The filtrate, on evaporation, yields a crystalline potassium salt of a new iron cyanide. It contains water of crystallisation, which cannot be expelled without decomposing the salt entirely. Its aqueous solution yields with ferric chloride a violet, and with copper salts a green precipitate. The new salt has probably the formula K_3FeCy_3 .—J. B. C.

PATENTS.

Improvements in the Method of producing Aluminium Chloride. C. A. Faure, New York, U.S.A. Eng. Pat. 11,020, February 20, 1888. 4d.

THE ore is heated to redness by a direct flame, with excess of air, and is then subjected, after the air and flame have been cut off, to the action of a mixture of petroleum vapour, or other similar substance containing carbon, and a gas containing chlorine, such as hydrochloric acid. Chloride of aluminium is produced, and may be condensed in any suitable manner.—A. W.

Improvements in the Production of Sulphur from Sulphuretted Hydrogen. E. W. Parnell and J. Simpson, Liverpool. Eng. Pat. 4648, March 27, 1888. 6d.

WHEN sulphuretted hydrogen is burned with a limited quantity of air in a brick chamber with the object of effecting the reaction $\text{H}_2\text{S} + \text{O} = \text{H}_2\text{O} + \text{S}$, it has been found that the sulphur produced is always far short of the theoretical quantity, the loss being partly due to the escape of sulphuretted hydrogen and partly to the formation of sulphur dioxide and polythionic acids, which latter are found mixed with the wet sulphur deposited in the cooling chambers. The thionic acids are formed by a reverse action between the sulphur and the aqueous vapour. When sulphuretted hydrogen and sulphur dioxide are brought into contact in the presence of water, the following reaction should take place: $\text{SO}_2 + 2 \text{H}_2\text{S} = 2 \text{H}_2\text{O} + 3 \text{S}$, but in practice the simultaneous formation of polythionic acids diminishes the yield of sulphur. The sulphur formed is not precipitated in the solid form to any considerable extent, but remains in a quasi-soluble condition in the acids simultaneously formed. If these be neutralised by calcium sulphide, the sulphur separates out. If these thionates (after neutralisation) be subjected to the action of heat and pressure of steam, they are decomposed with precipitation of sulphur and evolution of sulphur dioxide. Again, if the polythionic acids be treated with sulphuretted hydrogen, decomposition ensues with formation of sulphur. These phenomena are made use of in carrying out this invention. Sulphuretted hydrogen is burned with a limited quantity of air, and the hot gases are conducted to a cooling chamber, where sulphur is deposited with polythionic acids. The gases escaping from the cooling chamber, which should still contain sulphuretted hydrogen, is treated with an aqueous solution of sulphurous acid in a scrubber, when sulphur is formed along with a certain amount of polythionic acids. The liquid thus obtained is allowed to settle, and the supernatant liquor which contains the polythionic acids returned for repeated use in the scrubber. The wet mud and the wet sulphur from the cooling chamber are agitated with a solution of an alkaline sulphide, until the mass has an alkaline reaction. The mass is then subjected to heat and steam pressure, whereby sulphur and sulphur dioxide are formed, and under certain circumstances sulphuretted hydrogen. The gases evolved are conveyed back to any suitable portion of the plant.—S. II.

Improvements in the Manufacture of Ammonia and Ammonia Salts. M. N. d'Andria, Stretford. Eng. Pat. 5762, April 18, 1888. 4d.

A SOLUTION of commercial ammonium sulphate is boiled with magnesia or magnesium hydrate, whereby ammonia is liberated and magnesium sulphate left in solution in the still, which can be obtained by crystallisation. Magnesium carbonate may be employed in a similar manner, and in this case magnesium sulphate and ammonium carbonate are obtained.—S. II.

Improvements in the Manufacture of Ammonia and its Sesquicarbonate. R. E. Chatfield, Sewardstone. Eng. Pat. 6152, April 25, 1888. 6d.

A SOLUTION of ammonium sulphate is heated with magnesia in a still, ammonia being given off and magnesium sulphate in aqueous solution remaining in the still, which can be crystallised and prepared for the market as Epsom salts. The ammoniacal gas is absorbed in water. For preparing ammonium sesquicarbonate a closed vessel is charged with a cold aqueous solution of ammonia, and carbonic acid is admitted into the upper part of this vessel above the ammonia solution, until the solution attains a strength of about 20° B. The solution is then heated, and an additional supply of carbonic acid being admitted, ammonium sesquicarbonate is sublimed from it and collected in suitable receptacles.—S. II.

Improvements in the Production of Sulphur from Sulphuretted Hydrogen. E. W. Parnell and J. Simpson, Liverpool. Eng. Pat. 6175, April 26, 1888. 6d.

WHEN sulphuretted hydrogen is burned with a limited quantity of air, thionic acids are formed as by-products. The object of this invention is the treatment of these acids so as to get sulphur from them. It has been found that the thionic acids, if brought into prolonged contact with sulphuretted hydrogen, are decomposed into sulphur and water (see Eng. Pat. 4648).—S. II.

Improved Furnace for the Production of Carbonic Acid Gas and the Burning of Calcareous Material. P. M. Justice, London. From C. Dietzsch, Saarbrück, Germany. Eng. Pat. 16,472, November 13, 1888. 8d.

THE furnace described is of the two-storied or stage pattern. Limestone is charged into the upper chamber, which forms a preliminary heater, and when the charge in the lower or burning chamber is withdrawn, the charge from the upper chamber is pushed into the lower one. The carbon dioxide given off during the process of burning passes through the upper chamber and escapes through a pipe for use. Air is admitted into the lower chamber through a channel below the furnace shaft.—S. II.

Improvements in the Process of Manufacturing Bicalcareaous Phosphate, called Precipitated Phosphate. G. C. Dymond, Liverpool. From C. E. D. Winssinger, Brussels, Belgium. Eng. Pat. 17,945, December 8, 1888. 6d.

THE object of the process is to prepare precipitated bicalcium phosphate free from iron and alumina, and completely soluble in ammoniacal citrate of ammonium. Caustic soda and gypsum are or may be obtained as by-products.

The phosphatic mineral is treated with sufficient sulphuric acid to give an impure solution of phosphoric acid (A), and by filtration a residue of impure or phosphated gypsum. The iron is precipitated from A by cautious addition of carbonate of lime and milk of lime; the filter-press mud from this process is mixed with a fresh quantity of phosphoric acid liquor A, giving on filtration a mud of impure gypsum, and a liquor to which lime is added until precipitation begins, when sulphate of soda is added in sufficient quantity to precipitate all the lime present as gypsum on boiling. After filtering off this gypsum the sodium phosphate solution is treated with enough sodium carbonate to remove the iron, which is filtered off. The filtrate mixed with lime gives a precipitate of pure phosphate of lime and a filtrate of caustic soda. This precipitate mixed with the solution of mono-calcium phosphate first obtained by the addition of a little lime to A, is converted into bi-calcium phosphate, which is filtered off and dried. The process may be shortened in various ways.—J. M. II. M.

Improvements in the Manufacture or Production of Bisulphite and Metabisulphite of Sodium or Potassium. W. B. Giles, A. Shearer, and F. G. A. Roberts, Stratford. Eng. Pat. 18,775, December 22, 1888. 4d.

SULPHUROUS acid gas is passed over or through solid sodium or potassium bicarbonate, the sulphurous acid being thereby absorbed and a bisulphite or metabisulphite produced according to circumstances. If the operation be performed at a temperature below 60° F. a bisulphite (NaHSO_3 or KHSO_3) is the product of reaction. If, however, the material acted upon be kept at a temperature between 212° and 257° F., a metabisulphite ($\text{Na}_2\text{S}_2\text{O}_5$ or $\text{K}_2\text{S}_2\text{O}_5$) is produced. If no special means of cooling or heating during the operation be taken, a mixture of bisulphite and metabisulphite will be the final product.—S. II.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

PATENT.

Improvements in Gas-fired Kilns for Burning or Heating Pottery, and for other Purposes. J. Holroyd, Leeds, and A. Wilson, Stafford. Eng. Pat. 3583, March 8, 1888. *Sd.*

HEREIN is described an arrangement of plant whereby two or more kilns may be worked with one regenerator, although, as this latter is divided into two parts, there are practically two regenerators. Attached to each kiln are two chambers which act alternately as combustion chambers and as means of outlet for the burnt gases, whilst the two halves of the regenerator alternately heat the air or gas supply, and abstract heat from the escaping products of combustion.—A. R. D.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Metallic Salts of Resin Acids for Preserving Wood. M. Kretschmar. Chem. Zeit. **13**, 31.

Owing to the rise in price of carbolic acid (phenol), both in the crude and pure form, the author recommends the substitution of metallic salts of various organic acids for the purpose of preserving timber.

Colophony in conjunction with copper or zinc is recommended by the author, and is to be applied in the following way:—1,000 parts of colophony are dissolved in 3,000 parts of a 10·5 per cent. solution of sodium hydroxide by the aid of heat. The copper or zinc salt is dissolved in distilled or soft water to a 10 per cent. solution. The solution of the metallic salt is first applied with a brush until it is no longer readily absorbed, when it is allowed to dry and the solution of the resin in soda applied. A second coating of colophony is applied after the first has become dry, but in cases of soft wood, the fibres of which are readily acted on by the sodium hydroxide, the timber is afterwards washed with 5 per cent. acetic acid. Lastly, it is recommended that in case the wood is required to remain constantly in contact with water, an excess of colophony should be dissolved in the sodium hydroxide solution, which must be done by adding the last portions of colophony in small quantities at a time. After painting the wood with it and allowing it to dry for two days, any excess adhering to the outside may be rubbed off with tow.—J. W. L.

Various Chemical Wood-impregnating Substances. R. Rittmeyer. Dingl. Polyt. J. **271**, 228—239.

THIS paper is a historical description of the various methods which have been proposed and employed for impregnating wood for various purposes with preservative materials, together with a few results as to the efficiency of these materials and the methods of using them. The materials which have been used are:—Sulphates of copper, iron, zinc, and barium, chlorides of mercury and zinc, creosote, &c., and various mixtures of these substances. Tables by different authorities of the cost of impregnation are also given, as well as tables showing the quantities impregnated in one or two countries.—A. W.

X.—METALLURGY, MINING, Etc.

Silicon and Boron. L. Gattermann. Ber. **22**, 186—197.

Ir magnesium powder and quartz be heated in a test tube over the flame, a violent reaction occurs, and according to the proportions either silicon or magnesium silicide is produced—

If 1 grm. of sand and 1·5 grms. of magnesium powder be heated together and the blue half-melted product be introduced into concentrated hydrochloric acid, silicon hydride is evolved, which ignites spontaneously. If one part of magnesium powder be heated with four parts of sand, free silicon is obtained, and by fusing the product with zinc and allowing it to cool, the zinc may be dissolved and crystallised silicon obtained, or if chlorine be passed over the heated mass obtained by the above method, 100 grms. of magnesium yield 300 grms. of pure silicon chloride. Silicon bromide and iodide may be obtained in a similar manner. To obtain silicon chloroform the product of the above reaction is treated with dilute hydrochloric acid to dissolve out the magnesium oxide and then dry hydrochloric acid gas passed over the purified product; using 10 grms. of magnesium, 15 grms. of silicon chloroform are obtained. Silicon bromoform has also been prepared.

Boron may be obtained by heating anhydrous borax with magnesium powder. The product contains excess of borax, magnesium oxide, boron nitride, magnesium compounds, and boron. The first is dissolved out by water, the second with strong hydrochloric acid, and the boron may be obtained in the graphite form by dissolving in aluminium in a plumbago crucible. By passing chlorine over the crude product the trichloride of boron may be prepared; with 8 grms. of magnesium, 15 grms. of the trichloride are obtained. Magnesium powder may also be used for the reduction of other oxides.—J. B. C.

Amorphous Bismuth. F. Hérard. Compt. Rend. **108**, 293.

By applying to bismuth the method that was used to obtain amorphous antimony, amorphous bismuth has been obtained. Pure crystallised bismuth is heated to bright redness in a current of pure nitrogen; greenish vapours rise and are condensed in the cold parts of the tube in the form of a grey powder. Viewed under the microscope this powder presents the form of little beads in strings like amorphous antimony and amorphous arsenic.

The presence of nitrogen is necessary as in the case of antimony; other gases gave no result. The analytical numbers are 99·5 to 99·7 for 100 of bismuth; by taking the mean we get 99·6 for 100 of bismuth, 0·4 per cent. being oxygen. If the grey powder be heated in a current of hydrogen it loses 0·4 per cent. of its weight and a corresponding quantity of water is formed. The powder is therefore a mixture of bismuth and oxide of bismuth. This fact explains the melting point, which is 410° instead of 247°, the melting point of crystallised bismuth; but it does not explain the density obtained, which is 9·483, the density of a mixture of bismuth and oxide corresponding to the grey powder being 9·665. This makes it probable that the substance is amorphous bismuth.

The extreme state of division in which amorphous bismuth occurs makes it more sensitive to reactions than crystallised bismuth. Thus it is attacked so rapidly by nitric acid that it disappears instantaneously.—A. J. S.

On the Volatility of Iron and the Penetrating Power of its Atoms on Welding the same to Nickel. T. Fleitmann. Stahl und Eisen, 1889, 9.

THE author found that on welding iron and nickel together the iron penetrated into the nickel beyond the weld, and to such an extent that, on separating the two metals with dilute acid and dissolving off successive layers of metal from the welded side of the nickel plate with stronger acid,

it was not until three-fourths of the thickness had been removed that he found the metal contained only that amount of iron originally present. The nickel did not penetrate into the iron plate in the same manner. To ascertain the real nature of this, some nickel plates 0.7 mm. thick and 5 cm. square were placed alternately with plates of iron of the same size and 6 mm. thick, in a muffle, and heated for 64 hours to a red heat. The nickel plates were then fractionally dissolved and the iron estimated in each successive solution with the following results:—

Solution.	Weight of dissolved Metal.	Weight of Iron in Solution.	Percentage of Iron in the dissolved Metal.
1st	Grms. 0.595	Grms. 0.3236	54.4
2nd	0.590	0.0546	18.2
3rd	0.792	0.0209	2.7
4th	5.911	0.0620	1.05
5th	1.653	0.01925	1.16

The original nickel plate contained 1.10 per cent. of iron. The explanation given of the above is that iron is volatile at a temperature far below its melting point; and this is borne out by the fact that when iron is heated in the same neighbourhood with nickel, but out of contact with it, the surface of the latter becomes gradually impregnated with iron.

The ease with which a metal welds is influenced by the difference of temperature between its softening and fusing point. If a metal softens long before it melts, it readily welds; if the melting and softening temperatures be close together, the reverse is the case. Impurities which lower the weldability of a metal may do so either by lessening its softening power or by lowering its melting point and bringing it nearer the softening point. Thus the impurities of iron spoil its weldability. On the other hand, a small quantity of magnesium added to nickel raises its melting point 100° and very much increases its weldability. —A. W.

The Gold Mines of the Siebenbürgen. O. N. Witt.
Chem. Zeit. 13, 63.

THE gold of these mountains does not appear under the same circumstances as in the case of the mines of California or Venezuela. It is found here in the fissures which occur throughout the trachitic rock of this range, and which vary in width from 1—50 cm. The minerals which are contained in them do not as a rule completely fill them up, but merely coat them, the space left having been then at a much later period filled up with calcite, slowly deposited by the water which has trickled through. The gold occurs in the pure state, and also alloyed with silver, and at Nagyag as a telluride, and frequently as a double telluride of silver and gold and lead and gold. The former of these is sylvanite or "Schrifterz." The latter is called Nagyagite, and has the appearance of galena. It is a ditelluride of lead containing varying quantities of tellurides of precious metals. It also occurs in Offenbanya and Borneo.—J. W. L.

Improvements in Metallurgy. Dingl. Polyt. J. 271,
214-227.

PERINO'S method for treating copper pyrites, without roasting, with nitrate of iron for the extraction of copper, according to the Eng. Pat. 2019 of 1888, and Ger. Pat. 44,498 of 1888 (see this Journal, 1888, 389) is described. It is found that copper sulphate only goes into solution, and that the silver remains in the residue. Moreover, in the recovery of the nitric acid, only 5 per cent. of that originally employed is lost.

The method of Jurisch, precipitating basic sulphate of iron and afterwards oxide of zinc from waste liquors from copper extraction (see this Journal, 1888, 124) is also described. Mellmann makes phosphor-copper and phosphor-tin by converting in one operation alkaline phosphates, silica, and carbon into alkaline silicates, carbon monoxide and free phosphorus, which latter at the moment of liberation combines with the metal, according to the following reaction:—

A reverberatory furnace or a crucible is preferably employed, but a cupola may also be used. In the two former cases it is advisable to add some flux, such as soda or fluor spar, and in the latter clay should be used instead of silica, and the mixture made into briquettes.

In Parkes' process for treating gold and silver ores, 12 to 16 per cent. of lime or chalk and 5 per cent. of soda in the case of sulphides is found to be the best mixture. Ger. Pat. 45,013 of 1887. (See this Journal, 1887, 823.)

Rössler treats the silver obtained by cupellation with silver sulphate in order to eliminate the lead and bismuth it contains. The silver is melted in a graphite crucible, a little sand thrown on to prevent the latter being attacked, and molten silver sulphate is then gradually added. Lead passes out first as sulphate, and the bismuth towards the end of the operation. The last portions of slag are therefore kept separate and treated for bismuth.

Matthey separates gold and silver from bismuth by adding 2 per cent. of zinc to the molten bath. The noble metals rise to the surface with the zinc, leaving the bismuth pure. The scum is melted in a crucible with borax to recover gold. Lead and bismuth may be separated by a kind of Pattinson process, as the alloys of these two metals melt at lower temperatures than does the bismuth. Matthey also shows that bismuth can be purified from a small quantity of copper by melting it with bismuth sulphide. If arsenic, antimony, lead, and tellurium be present, they are separated first in the usual way. By this process pure bismuth can be obtained from material containing from 0.1 to 1.0 per cent. of copper.—A. W.

The Croselmire Zinc Process. Eng. and Min. Jour.
1889, 135-136.

THIS is a description of the practical working of Croselmire's patent which has already been described (this Journal, 1888, 678). The blende is crushed (or tailings containing blende may be used) and made into bricks with clay by an ordinary brick-making machine, each brick having three transverse holes an inch in diameter through it. These when dry are piled in a cylindrical kiln, one on the other, so that the holes form a series of flues. On the inside wall of the kiln are tiers of steam pipes, each having a number of iron nipples which project into the interior. At the base of the kiln are four fire-boxes in which the heat is generated to start the process. When the sulphur of the ore commences to burn the firing is stopped, and steam and air are introduced by means of the jets. The operation lasts about a week, the temperature all this time never being allowed to rise above a dull red heat. After the operation is complete, and when the kiln is cold, the bricks are removed and leached with hot water, when the zinc, which is in the form of sulphate, is, together with some iron, dissolved out. The liquor is decanted, the iron precipitated as oxide, and from the solution the zinc is precipitated with soda-ash. The residue from the leaching vat contains the lead, silver, and gold of the ore, and when mixed with the oxide of iron precipitate is sold for smelting. It contains, however, 4 or 5 per cent. of zinc. It is maintained that the process is easy of manipulation, and inexpensive, 1,000 lbs. of slack being used for a charge of 30 tons of tailings, containing 24 per cent. of zinc. The by-products also can be made use of, the sulphurous acid for vitriol making, and the final liquor for sulphate of soda.—A. W.

PATENTS.

Improvements in the Treatment of Refractory Gold and Silver Ores, and in Apparatus therefor. H. Hutchinson, London. Eng. Pat. 16,270, November 26, 1887. 8d.

THIS is a form of furnace for roasting or chloridising gold or silver ores. Gases from a gas-producer are made to burn in a vertical chamber through which pass a series of tubes, and the products of combustion are passed into and down another vertical chamber, in which the ore is calcined. This calcining chamber contains a series of shelves or baffle plates, from one to the other of which the ore, which is introduced at the top, falls in its passage downwards. The series of tubes, through which air passes, also open into this chamber, so that the ore in its descent is subjected to the action of heated air as well as to the heat of the burnt gases. The gases from the calcining chamber are passed into and through a large chamber, to allow the fine dust to settle, and then through flues at the top, whereby the upper surface becomes heated, and can be used as a drying plate. The calcined ores can be afterwards treated for gold and silver by any known method. Drawings are given.—A. W.

Improvements in Appliances for Amalgamating Auriferous and Argentiferous Substances. E. J. Ball and B. H. Brough, London. Eng. Pat. 16,862, December 7, 1887. 8d.

THE amalgamator consists of a series of conical plates A A' on a spindle supported at D, under and around each of

which runs a slanting circular plate F F' attached to an outside removable casing G. The pulp is fed in through the distributor B, and is washed alternately over these series of cones and plates into the chamber H, either or both of which series can be made to revolve. K and K' are sweepers, to prevent undue settling and blocking, and I is a water-supply pipe, to assist in the removal of the tailings through L. Electricity may be employed with this apparatus, and conoidal or pyramidal surfaces, with or without corrugations, are also claimed.—A. W.

Improvements in the Treatment of Zinc and its Ores. A. Watt, London. Eng. Pat. 3369, March 5, 1888. 6d.

IN a previous specification (this Journal, 1888, 328) the patentee claims the use of vegetable acids for preparing the electrolytic bath. He finds, however, that when lead is present, it interferes with the proper deposit of the zinc.

He now claims the idea of adding to the bath sulphuric acid, which precipitates the lead as sulphate. Impure zinc, containing lead, can be used as the anode in this case. When lead is present in large quantity, the ore or metal is treated first with acetic acid, which dissolves the lead, and afterwards with dilute sulphuric acid. The lead is precipitated from the acetate solution by scrap zinc, and the solution of acetate of zinc so produced added to the solution of sulphate to make up the bath for electrolysis.—A. W.

Improvements in the Manufacture of Ingot Iron and Steel. T. Wynam, London. Eng. Pat. 5084, April 5, 1888. 6d.

OXIDE of iron in any form, but not too silicious, is mixed with coke dust, and evenly placed on the hot bed of a neutral or basic-lined open-hearth furnace. This is covered with a layer of lime, upon which is charged pig-iron, which may be rich in phosphorus but not in silicon. The pig, which may be run in molten or placed in the furnace cold, should amount to not less than one-third the quantity of iron in the ore or oxide used. The charge is melted, rabeled, and worked down into ingot iron in the usual way.—A. W.

Improvements in Blast Furnaces. W. Evans, Merthyr Tydvil. Eng. Pat. 5665, April 17, 1888. 11d.

AN extra set of tuyeres, similar in construction and arrangement to the ordinary, are placed higher up in the furnace, preferably about 8 or 10 feet below the boshes. Suitable arrangements are made for governing the blast through these tuyeres. By their use it is maintained that a large yield of metal with a moderate pressure of blast is ensured, that the life of the furnace is prolonged, and that "scaffolding" is prevented, and consequently a better and more regular product obtained. Full drawings are attached.—A. W.

Improvements in the Method of and Apparatus for Reducing Ores or Compounds of Zinc, Iron, Phosphorus, Sodium, and other Substances. G. M. Westman, New York, U.S.A. Eng. Pat. 17,336, November 28, 1888. 8d.

BY an elaborate system of pipes and valves, and with the aid of a blast engine, carbonic oxide gas is drawn through a regenerator, where it becomes highly heated, into a reducing furnace, wherein are the ores to be reduced, through condensers and coolers, back again into the regenerators. Zinc or iron ores are reduced by this plant, the former being mixed with coal. The zinc is volatilised and condensed. In the case of iron, the ore is introduced alone into the furnace, and becomes reduced to a sponge. Phosphorus and sodium can also be manufactured by using mixtures of phosphate, silica and coal, and carbonate of sodium and coal, respectively. Six drawings are given, showing the general construction and arrangement of the furnaces, &c., and some of the valves used.—A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Electrolysis of Cryolite. W. Hampe. Chem. Zeit. 13, 29 and 49—50.

THE author has made the following further experiments:—

When cryolite and sodium chloride are melted together at a temperature of 700°—1,000° no aluminium chloride is evolved, nor even formed in the flux, the only substances passing out of the retort neck being a small quantity of volatilised cryolite and a gas which etches glass, besides sodium chloride. The reduction experiments were carried out preferably in crucibles of retort graphite or powdered coke, to which latter a small quantity of tar was added. The current obtained from a zinc-iron battery varied from 0.5 to 50 amperes.

If pure cryolite be electrolysed at a temperature approaching to or exceeding $1,054^{\circ}$, the melting point of copper, the liberated sodium is evolved in the form of vapour. Fluorine is evolved from the anode, while bubbles of sodium form and rise from the cathode. The latter are, however, absorbed for the most part by the cryolite, a lower fluoride of aluminium being formed. This circulates through the liquid mass and becomes gradually changed again to the original fluoride by the fluorine evolved at the anode. In consequence of this reverse action taking place the amount of aluminium obtained is extremely small. In one experiment, lasting for 20 minutes, with a current strength of 2.7 amperes, 0.0875 gram of aluminium instead of 0.505 was obtained from a copper regulus of 8.829 grams.

If, on the other hand, the electrolysis of pure cryolite be conducted at a temperature but little above its melting point, sodium is deposited at the negative pole as a liquid which reduces the aluminium in the form of globules, which, owing to the lesser surface exposed to the melted cryolite, do not form the lower fluoride so rapidly, and the aluminium forms, too, a bronze with the copper, which further retards the formation of the lower fluoride. This solvent action is however by no means altogether overcome, and the amount of aluminium obtained varied up to one-fourth or one-third the theoretical quantity. The addition of common salt to the cryolite lowers the melting point of the latter, and thus enables the reduction to be carried out at a lower temperature, and a somewhat larger production of aluminium is attained. Experiments showed that another source of loss of aluminium arises towards the end of the electrolysis, when the sodium does not readily come in contact with aluminium fluoride, and an alloy of sodium aluminium is formed and rises to the surface, there burning to the respective oxides.—J. W. L.

Electric Welding. Engineering, 1888, 571.

THE process of electric welding invented by Professor Elihu Thomson has been subjected to a number of tests at the United States Arsenal, Watertown, Mass. The test pieces included wrought iron, octagonal steel, steel and wrought iron, copper, brass, brass and wrought iron, and copper and German silver. The bars varied in diameter from .25 in. to 1.74 in. The general results of the tests shows that an electric weld, like a hand-made one, may be good or bad. The proper conditions for constant success do not appear yet to be understood, but the experiments, so far as they have been made, justify the expectation that the new method will become of great practical value. The apparatus used is of two forms. Either the current is supplied to the bars by the aid of an alternate current transformed, or directly from an alternate current dynamo. The bars to be welded are held by clamps, so that the ends to be welded are in contact. When the bars are in connexion with the source of current, the metal softens at the joint, and the clamps holding the bars are fed forward so as to force the two surfaces together. The process is complete in a time varying from a fraction of a second to two minutes. With the large bars, the current employed amounts to thousands of amperes.—W. W. H. G.

Electric Welding. Eng. and Min. Jour. 1889, 136.

A NUMBER of illustrations are given contrasting the welds made by hand and by the Elihu Thomson electrical method. They show that the line of junction for electrically welded iron bars is stronger for an equal sectional area than the original bar, apparently owing to the elimination by the process of fusion of the cinder present in all wrought-iron bars. If the welded bar be filed down to the centre line to obtain a section of the joint, the microscope will show that the iron at the weld is denser and more homogeneous in structure than the other parts of the bar. With an ordinary hand-made weld, the actual separation of the surfaces supposed to be welded may be seen without the aid of a microscope.—W. W. H. G.

Apparatus for obtaining Aluminium. Centr. für Electro-techn. 1888, 10, 844.

THE apparatus as used by the Schweizer metallurgischen Gesellschaft in Neuhausen is thus described. Two dynamos giving together 12,000 amperes at 20 volts produce the necessary current, the magnets of which are excited by means of a small dynamo. Each armature possesses two collectors of considerable length, on which six sets of six brushes each are caused to rub. The convolutions of the armatures are presented to the collectors alternately, so that two separate armature convolutions are, as it were, on one centre. The brushes of similar polarity on each collector are connected with the centre of the collector by means of strong cables. The dynamos make 180 revolutions per minute, the motion being transmitted by means of a turbine, itself worked by the flow of the Rhine. The reduction is carried out in a cube-shaped carbon crucible, which is bound round by a metal casing, and which is connected with the negative pole of the dynamo. The positive pole consists of a bundle of carbon plates, which are let into the crucible. Aluminium bronze and ferro-aluminium are the products of the Héroult process.—J. W. L.

The Disintegration of Anodes by Electrolysis. E. Wohlwill. Dingl. Polyt. J. 271, 222—223.

THE author discusses the so-called disintegration of copper regulus anodes, and explains the action in the following manner:—It is known that cupric sulphate takes up metallic copper from the anode of a copper-refining bath with the formation of cuprous sulphate, this being afterwards decomposed into cupric sulphate and metallic copper again. So also in the case of the regulus the compound richer in copper is produced at and around the anode, and becomes decomposed again directly it gets outside the sphere of formation. It is to the copper derived from this decomposition that the phenomena observed are due, and not to any real disintegration of the regulus itself. It is found that the action diminishes with the density of the current employed.

—A. W.

PATENTS.

Improvements in the Method of and Means for Separating Matters in Solution by Osmose, Dialysis, or Diffusion, or by Electrolysis, or by a Combination of those Processes. J. Marx, Ulm, Germany. Eng. Pat. 2367, February 16, 1888. 8d.

IN the processes of separating matters in solution by dialysis, diffusion, or electrolysis, or by a combination thereof, as hitherto conducted the soluble bodies sooner or later cause a stoppage of the process. The author removes "the prime cause of this evil" by precipitating the soluble bodies after the reaction has commenced but before it could be stopped again by the increasing accumulation in the solution of the soluble bodies; and the effect of the new process is greatest if the precipitation be effected by the measure of "the diffusion or production of these soluble bodies." The present invention relates to the use of a process for the precipitation of dialysed bodies, and to means and methods, by osmose and electrolysis, for treating compounds yielding soluble products under electrolytic action, and by a combination thereof. The process is preferable in which osmose is combined with electrolysis, when the electrolytic products may be led off continuously; or the osmose may be worked along with electrolysis assisted by the precipitation method. A special diagram is described, made by arranging together rods, sticks, pipes, &c., in any suitable manner.—B. T.

Improvements in Electrical Batteries and Methods of Closing the same. F. L. Rawson and W. White, London. Eng. Pat. 4593, March 26, 1888. 8d.

A STOPPER of hard wood is fixed in the outer case of the cells and acts as a stuffing-box, having a receptacle at the top to contain material such as glass or slag wool, through which the gas generated can pass easily, but through which the liquid can only pass slowly.—B. T.

Improvements in Fusible "Cut-Outs" for Electrical Circuits. A. H. Walton, Barnsbury. Eng. Pat. 5233, April 9, 1888. 8d.

Each lamp wire in a building is brought to one central position where it is attached through a fuse to a contact bar connected with the mains. Contact is made with the fuse by a spring.—B. T.

An Improvement in Plates for Voltaic Batteries. E. Hermite, E. J. Paterson, and C. F. Cooper, Dalston. Eng. Pat. 5528, April 13, 1888. 4d.

WIRE of a costly material, such as platinum, is used for battery plates, the inventors draw the material out into fine wires, and then weave these wires into a gauze, thus obtaining a large surface, able to withstand rough usage, with a comparatively small expenditure of the metal.—B. T.

The Production of Chalybeate Waters by Electrolytic Action, and Apparatus therefor. W. Webster, London. Eng. Pat. 5723, April 17, 1888. 6d.

SALTS of iron are formed in potable water containing chlorides, sulphates, &c., by immersing in the water a plate of iron and passing an electric current through it, using this iron as the positive electrode. A second plate of iron separated from the first by a porous partition may be used as the negative electrode.—B. T.

Improvements in and relating to the Preparation of Non-Metallic Porous Surfaces for Electro-Metallurgical Deposits. H. Steinach, Munich, Germany. Eng. Pat. 5790, April 18, 1888. 6d.

THE surfaces are immersed in melted tar which has been purified by means of sulphuric acid and soda lye and to which 10 per cent. of paraffin has been added. To remove any superfluous tar, the objects are exposed to a blast of hot air or dry steam.—B. T.

Improvements in the Manufacture of Depolarisers for Electric Batteries. M. Leclanché, Paris, France. Eng. Pat. 8354, June 7, 1888. 6d.

A SOLUBLE pulverulent material, such as potassium carbonate or copper sulphate, is added to the depolarising mixture before it is moulded, and is afterwards dissolved out, leaving the agglomerate body very porous.—B. T.

Improved Machines for Making Battery Plates. O. E. Madden, Boston, and A. F. Madden, Newark, U.S.A. Eng. Pat. 15,252, October 23, 1888. 8d.

THIS apparatus consists of a die and plunger for stamping out battery plates of the desired form, and includes an arrangement for shaving off and removing the surplus metal. The plunger has a serrated face to prevent spreading of the metal.—B. T.

Improvements in Secondary Batteries. P. A. Fichet and A. Nodon, Paris, France. Eng. Pat. 15,369, October 25, 1888. 8d.

IN the construction of their reversible batteries, the authors, to obtain simple reactions indefinitely reversible, give preference to primary combination taking place by two elements only, e.g., combination of a metal and a halogen, chlorine, bromine, or iodine, with formation of a metallic chloride, bromide, or iodide. The halogen is employed in a state of chemical combination from which it may be easily taken as required to be furnished to the metal. Several combinations of halogens with alkaline or alkaline-earth metals may be employed, and to increase the stability of these in the presence of water, they are dissolved in a solution of a salt which has combined with water with great evolution of heat. The single element is composed of a recipient and two electrodes separated by a porous diaphragm. If in series, one side of a carbon plate may be used as the positive electrode, and the other side as the negative electrode. The carbon plates are impregnated with paraffin which has been subjected to the action of chlorine.—B. T.

Improvements in or relating to Secondary or Storage Batteries. W. P. Thompson, Liverpool. From C. H. Thompson, Detroit, U.S.A. Eng. Pat. 16,048, November 6, 1888. 8d.

MOLTEN lead is poured into a mould of suitable size filled with a soluble, coarse, granular salt, able to stand a high temperature, and the whole mould is heated to ensure that the lead shall fill all interstices. When cool, the lead is cut into plates of the desired thickness and the salt dissolved out, leaving a very porous lead plate, the pores of which may be filled with the salts of lead proper to a secondary battery.—B. T.

Improvements relating to the Generation of Electricity and the Simultaneous Production of Zinc Chloride and other By-Products. L. Paget, New York, U.S.A. Eng. Pat. 17,225, November 27, 1888. 8d.

CHLORINE gas is generated by the action of sulphuric acid on bleaching powder and is then passed into a galvanic cell, where it acts as the excitant. The by-products obtained by this process are valuable commercially.—B. T.

Improvements in Electro-Depositing Cells. P. M. Justice, London. From E. L. Smith, Ansonia, U.S.A. Eng. Pat. 17,340, November 28, 1888. 8d.

THE copper to be deposited is cast in plates of the proper size and form, these plates being suspended in layers horizontally in the solution. The bottom layer rests at the ends on two strips of wood, the upper layers being held the right distance apart likewise by strips of wood. Cotton cloth is stretched from strip to strip between each layer to separate and save the insoluble foreign substances obtained, pure copper only being deposited on the upper surface of the plates. The top layer is used as the anode and the bottom as the cathode, the spaces between the layers forming separate cells in series. Thus copper is deposited from the under surface of the top layer upon the top surface of the second layer, and so on through the series, until the original copper of each plate has been deposited upon the plate below.—B. T.

Improvements in Apparatus for Indicating the Completion of the Charging of Secondary Galvanic Batteries. S. C. C. Currie, Philadelphia, U.S.A. Eng. Pat. 17,645, December 4, 1888. 8d.

THE spray rising from accumulators in which the liquid is in a state of ebullition, is deposited on plates arranged over the cells, where it collects in drops, and in this state bridges over two pieces of metal arranged close together, thus completing an electric circuit and ringing a bell to attract attention.—B. T.

Improved Apparatus and Connections for Charging and Discharging Storage Batteries. W. P. Kookogey, Brooklyn, U.S.A. Eng. Pat. 319, January 8, 1889. 8d.

BY means of an automatic commutating device, when lamps are being lighted from the storage battery, the cells are all connected in series and disconnected from the charging system, but, when no lights are on, the storage cells are connected in parallel and are in circuit with the charging system, but disconnected from the lamp circuit.—B. T.

Dry Galvanic Cells. C. H. Mehner, Berlin, Germany. Eng. Pat. 434, January 9, 1889. 4d.

INSTEAD of sponge, saw-dust, &c., being used as the vehicles for absorbing the liquid excitant, a "mineral gelatin" consisting of crystallised hydrated basic chloride of magnesium is employed, which is itself an exciting agent.—B. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Refuse from Olive-Oil Factories. Sestini and O. Tobler. Chem. Centr. 1888, 634.

In Italy, the water used in pressing the crushed olives passes through a series of tanks, and the deposit which collects in the last tanks of the series is used as a manure, and is known as "morchione."

Two samples of "morchione" from a good mill were found by Sestini to have the following composition per cent. :—

From	Undried Mud.	Air Dried.						
	Water.	Water.	Ash.	Organic Matter.	Fat.	N.	P ₂ O ₅ .	K ₂ O.
Last tank but one :.....	68.20	20.10	20.33	59.57	0.59	2.01	0.17	0.10
Last tank :.....	71.26	27.82	7.52	64.65	1.51	2.18	0.17	0.12

whilst a sample from another mill with fewer tanks contained H₂O, 7.87; oil, 11.28; organic matter, 76.21; ash, 4.64; and N, 1.63 per cent. respectively.

Tobler points out that these residues are not economically employed as manure or fuel, since, owing to the large percentage of fat and albuminoids they contain, they form a good food for cattle. Taking the nutritious value of hay at 6.5 frs. per 100 kilos., these residues have a value of 11.95 frs., and they cost on the spot only 7 frs. per tonne (20 ctrs.).—D. A. L.

PATENTS.

Improvements in obtaining Fatty Acids and Glycerin from Fats and Oils. J. Lewkowitsch, Leeds. Eng. Pat. 5985, April 21, 1888. 6d.

The fats and oils are decomposed by superheated steam in the usual manner, but the whole process is conducted in a partial vacuum ("a minus pressure of 10 to 13 lb.") at about 460° F., instead of 600° as usual. The supply of steam may be less, and the temperature may vary within much wider limits than in the ordinary process as conducted at atmospheric pressure.—W. L. C.

An Improved Soap. T. S. Saunders, London. Eng. Pat. 5981, April 21, 1888. 4d.

Small quantities of unsaponified fat are incorporated with finished soap to neutralise the free alkali and the alkali set free when the soap is dissolved in water in its ordinary use.—W. L. C.

Method of Extracting or Winning Wool-Oil ("Lanolin") in a Mechanical Way. A. J. Boulton, London. From O. Korschelt, Zittau, Germany. Eng. Pat. 6669, May 4, 1888. 6d.

The dirt is separated from the previously warmed washwaters by a centrifugal machine with several concentric drums, and the waters are then conducted into a series of separators. The greasy emulsion here obtained is put into settling reservoirs, where the wool-oil rises to the surface.—W. L. C.

Method of Extracting or Winning Wool-Oil ("Lanolin") in a Mechanical Way. A. J. Boulton, London. From O. Korschelt, Zittau, Germany. Eng. Pat. 6671, May 4, 1888. 4d.

The wool emulsion, previously freed from dirt, is subjected to continuous agitation in a mechanical agitator. The lanolin separates on the surface in small particles, which rapidly agglomerate.—W. L. C.

An Improvement in the Manufacture of Soaps. J. Taylor, Leith. Eng. Pat. 7830, May 29, 1888. 4d.

MELTED paraffin, or petroleum seal or wax, is incorporated with the soap as it is removed from the soap-pan.—W. L. C.

Improvements in or relating to the Treatment of Oil-Bearing Substances during the Expression of the Oil, and in Presses applicable for Receiving and Discharging such Substances without intermission. W. P. Thompson, Liverpool. From M. Crawford, Brooklyn, U.S.A. Eng. Pat. 14,526, October 9, 1888. 8d.

This press is continuous in its action, and the material under treatment is heated while in the press. It consists essentially of two steam-jacketed cylinders, mounted eccentrically, so that when they are revolved the material between them is subjected to a gradually increasing, and finally enormous, pressure. End plates prevent the escape of solids, while the expressed oil runs away through porous material. No claim is made for any single individual piece of mechanism, but for the combination forming the machine. Drawings are given.—W. L. C.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

Egyptian Blue. F. Fouqué. Compt. Rend. 108, 325—327.

This is a blue colouring matter which was used by the Romans in the first few centuries of the Christian era, but ceased to be manufactured about the time of the invasion of the barbarians. It figures in several beautiful frescoes in the Vatican, and has also been found at Pompeii. The author has discovered the composition to be that of a double silicate of calcium and copper, CaO, CuO, 4 SiO₂, devoid even of traces of alkali. The substance is crystal-

line, and is hardly attacked by any chemical reagents, which explains the perfect state of its preservation in the paintings for which it was employed 1,900 years ago. It may be prepared at a bright red heat, but this temperature must not be exceeded, as it is then decomposed into cuprous oxide, wollastonite, and a clear light-green glass. The higher the temperature the more of the latter is formed, and finally wollastonite disappears entirely. By the old method of preparation, described by Vitruvius, fine sand and soda are intimately mixed with copper filings, then moistened with water, formed into cakes, and the latter dried. The cakes are then fused in an earthen pot until the blue colour is produced. The author finds this method practicable, but uses potassium sulphate in preference to soda as a flux. He has not found it possible to replace chalk or lime by magnesia. The ancient Romans employed a large excess of silica, whilst the author employs more basic mixtures, finally purifying the product with hydrochloric acid. The exquisite colour of this mineral body, the fact that it is absolutely unaffected by moisture, light, and most chemical reagents, as well as the facility and the low price of production, render it desirable that its manufacture should be again resumed.—A. R.

On the Optical Properties of Genuine and Spurious Amber. G. Weiss and Erekmann. *Compt. Rend.* 108, 376–377.

IMITATION amber is now largely manufactured from shavings of natural amber, presumably by strong pressure. Real amber shews double refraction since light is transmitted through two Nicols placed in opposite positions by interposing a segment of amber. This light varies on turning the amber, and there is total extinction for two positions of 90°. Imitation amber is also doubly refracting, but instead of the shade of the transmitted light being uniform the same phenomena are observed as with a segment of rocks containing crystals lying in different directions. For all practical purposes it is only necessary to examine the piece of amber in polarised light by means of an analyser and magnifying glass to see at once whether the article be genuine or spurious.—A. R.

PATENTS.

Improvements in the Manufacture of Enamel and other Paints or Varnishes. F. Fisher, Belfast. *Eng. Pat.* 5878, April 20, 1888. 6d.

THE patentee heats the "spirit, shellac, and varnish, or other solvent," until 25–35 per cent. of it has evaporated, "and all the volatile oil has been driven out of the crude spirit, and a perfect mixture of the solvent completed," and adds, after cooling, the necessary pigments or resinous substances, then continues the cooling to as near 32° F. as possible, transfers the mixture to cans capable of being closed air-tight, introduces a few drops of some perfume, seals the vessels and shakes to effect perfect admixture.

—B. B.

Compositions for the Coating and Preservation of Iron, Steel, or Metal Structures from Corrosion, and Apparatus for the Application of the same. E. F. Wailes and E. J. Dove, Newcastle-upon-Tyne. *Eng. Pat.* 6012, April 23, 1888. 8d.

A SOLUTION is made of 1 cwt. of natural or manufactured asphalt, together with 28 lb. of "grease or oil," in 20 gallons of "spirits of naphtha." The metal structures to be treated are coated with this, used slightly warm, and when dry, one or more coats of a composition consisting of 1 cwt. of natural or manufactured asphalt, 50 lb. of pitch, 25 lb. of chalk, 35 lb. of Portland cement, 1 gallon of oil, and 7 lb. of resin, are put on hot. To conveniently effect this, the mixture, after being melted in one main cauldron near the place where it is to be used, is distributed to the work in steel cans provided with an outer casing and heated by spirit or oil lamps, or by coke or charcoal. Drawings of the paint-can are given.—B. B.

An Improved Composition or Varnish for the better Protection of Iron Plates, Tanks, Ships, and the like from the Action of Petroleum and similar Substances. A. Andrews, New Southgate, Eng. *Pat.* 12,827, September 5, 1888. 6d.

Six lb. of shellac are dissolved in 16 lb. of methylated spirit, 1 lb. of boiled oil added, and 2 lb. of oxide of iron stirred in; the proportions may be varied and gum mastic and graphite used in addition. The novelty claimed is the use of the boiled oil to give elasticity to the product.—B. B.

Improvements in the Manufacture and Application of Waterproof Fabrics. D. Nicoll, London. *Eng. Pat.* 13,971, September 28, 1888. 6d.

THE patentee mixes anthracene or some similar hydrocarbon with two of the ingredients mentioned in *Eng. Pat.* 2480 of 1867, viz., "cotton foots' pitch" and "epurée" (purified pitch) of Trinidad in the proportion of 15 parts of the first to 200 of the second and 85 of the third, producing a composition that can be used for waterproofing any suitable woven fabric, which can be then manufactured into tubes, troughs, pontoons, tarpaulin, &c.—B. B.

New or Improved covering Composition applicable for Protecting Ships' Bottoms and the like. F. J. Binns, Ripon, and R. J. Paris, Liverpool. *Eng. Pat.* 17,946, December 8, 1888. 6d.

SIXTY to 80 per cent. of zinc in powder is mixed with 20 to 40 per cent. of carbon in the form of graphite or gas carbon, and made into a paint with any suitable vehicle such as oil, tar, or varnish. An appropriate pigment may be added if desired. The composition when applied to ships' bottoms is said to prevent the formation of marine growths thereon, a result attributed to electric currents set up by the action of the salt water on it.—B. B.

Improvements in the Manufacture or Production of Lead Pigments. J. Y. Johnson, London. From A. G. Fell, New York, U.S.A. *Eng. Pat.* 722, January 15, 1889. 6d.

THE pigment patented is a basic lead sulphite, which may be produced by the action of sulphur dioxide on any suitable salt of lead, such as the basic acetate. In general the process is carried out as follows:—"The lead in a granulated or spongy condition is placed in a series of suitable vessels (e.g., wooden tanks), and the first of these filled with dilute acetic acid containing about 2.5 per cent. of the anhydrous acid; digestion is allowed to proceed for about 30 minutes, when the liquid is drawn off into the second vessel, where it remains for the same length of time, and so on to the end of the series (three vessels are generally found sufficient). The lead, after the acid liquor is drawn off, oxidises by contact with the air and yields more acetate on passing the liquor over it again; the final product has a density of 15°–20° B., and consists of a solution of basic lead acetate. Through this solution, contained in deep tanks, sulphur dioxide is forced, precipitating lead sulphite, which is filtered off and steamed either when in the press or afterwards; the steaming probably removes a portion of the combined sulphur dioxide and leaves a basic lead sulphite, which is dried and ground in oil ready for use. In the case of a lead salt less soluble than the basic acetate being selected, it is treated in the form of a paste in shallow troughs with the sulphur dioxide.

The advantages claimed for the pigment are its great "body," comparative resistance to the action of sulphuretted hydrogen, and the certainty of the manufacture as compared with that of white lead. Further, the acetic acid can be used repeatedly, being recovered in the form of the filtrate from the lead sulphite.—B. B.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENTS.

Improvements in and relating to the Tanning of Hides and Skins. G. W. Rhodes, North Finchley. Eng. Pat. 1818, February 7, 1888. 8d.

A TANK is used divided into compartments or channels communicating at their ends in such a way that a continuous current of tan liquor can be sent through by means of a suitable motor. The hides are hung in rows in this pit and electrodes are placed in between them in such a way that the anodes and cathodes follow each other alternately. The cathodes are of copper and the anodes of platinum gauze or carbon, and are placed in porous diaphragms. The electric current should be used intermittently. Any tanning liquor may be used, and the tanning is much helped by warming to 96° F. A drawing is given, and for further particulars the specification must be consulted.—B. II.

Improvements in the Treatment of Bones and Animal Waste or Refuse generally for the Purpose of rendering the same more suited for Fertilising Purposes, and for obtaining Gelatin, Glue, and Size. A. H. Hobson, London. Eng. Pat. 4765, March 28, 1888. 6d.

THIS invention is for rendering bones and other animal refuse more suited for use as a manure, and also for obtaining glue or size therefrom. For the production of manure only the bones in the form of powder are heated with about 10 per cent. of their weight of caustic potash, or equivalent of other alkali, and an equal weight of water to 180°–210° F. for 9–10 hours. The mixture may be used either as liquid manure or evaporated to dryness before using. When size and manure are both wanted the bones are heated with about 3 per cent. of caustic potash for 5–15 hours at 180°–200° F. The solution is separated from the sediment, and evaporated at about 160°–180° F. to a suitable consistency for use as size, &c. More potash may then be added to the sediment and the heating continued till all the nitrogenous matter is dissolved.—B. II.

Improvements in Tanning. H. Levick, Grantham. Eng. Pat. 6491, May 1, 1888. 8d.

THIS invention is for lifting apparatus for raising the hides from the tan-pits and dispensing with the use of hooks, which often cause injury to the grain of the leather. For this purpose ropes are employed which pass beneath the bottom hide in the pit. One end of each rope is fixed near the top of the pit on one side, and the other end is brought up out of the pit on the other side. By tightening the ropes all the hides are raised and can be removed one by one by the workmen. A winch is employed to shorten the ropes when desirable. Drawings are given.—B. II.

An Improvement in the Treatment of Hides for Belting and such like Purposes. C. L. Royer, Halifax. Eng. Pat. 7007, May 10, 1888. 4d.

IN preparing hides for belting, &c. it is usual after unhairing to partially tan the hides, dry them, soak them in water, and after seasoning to grease and full them. The improvement consists in drying the hides after unhairing, "but without any tanning," steeping them in water, and then fulling them with non-oleaginous substances such as keratine, flour, glycerin, ox-gall, and soap. After fulling, the hides are soaked in water for several days, and the substance used for fulling removed. The hides are then tanned, greased, and dried, and after the excess of grease is removed the hides are ready for being cut into belting.—B. II.

A New or Improved Process for the Preservation of Extracts and Liquids Containing Tannin, and Used for Tanning Purposes, by Means of Creosol, Naphthol, Creosotic Acids, Naphthoic Acids, and their Soluble Salts, as well as a Process for Preserving Kips, Skins, or Hides by Means of Creosol, Naphthol, and their Carbon containing Acids in suitable Solution or Mixed with suitable Solvents. J. Hauff, Feuerbach, Germany. Eng. Pat. 18,307, December 14, 1888. 6d.

AFTER stating the inefficiency of phenol and salicylic acid and the objection to salts of mercury on account of their poisonous properties, the patentee states that by adding one part of creosotic acid to 2,000 parts of the liquid to be preserved, and one part of either α - or β -hydroxy-naphthoic acid to 5,000 of the liquid, complete preservation is effected. To preserve tan liquor the proper amount of the acid or of its soluble salt should be added to it with constant stirring. 100 kilos. of an extract containing 25 per cent. of tannin is dissolved to a lye of 5 per cent., and to it is added 100 grms. of the sodium salt of hydroxy-naphthoic acid. Kips or skins may be preserved by having the substance rubbed over them, or they may be treated with a solution of the substance in alcohol or glycerin.—B. II.

XV.—AGRICULTURE, MANURES, Etc.

Manurial Efficacy of Various Phosphates. J. Raulin. Comp. Rend. 108, 64–66.

EXPERIMENTS with maize in 1887, and with wheat in 1888, show that coprolites and phosphates, if finely ground, will give results comparable with those given by superphosphate and precipitated phosphate, provided that in the first year they are applied in five or six times the usual quantity. The author gave coprolites equal to 200 kilos. of P_2O_5 per hectare in the first year, and in the second year to 40 kilos. of P_2O_5 . The Crenzot slag or basic slag gave bad results, but they are attributed to the fact that the mixture employed contained ammonium salts, the ammonia being rapidly expelled by the alkaline slag.—J. M. H. M.

Early and late Varieties of Sugar Beet. C. Violette and F. Desprez. Compt. Rend. 108, 66–69.

THE rich varieties of sugar beet cultivated of recent years in France are late in habit. The authors' experiments show that by judicious selection, seed roots combining earliness and richness in sugar may be obtained. Of the 10 varieties of seed experimented with, four are classed as early and rich, four as late and rich, and two as early and poor. Those in the first category produced ripe roots in the last fortnight of September, at Cappelle (Nord).—J. M. H. M.

Absence of Nitrates in Forest Trees. E. Ebermayer. Ber. d. deutsch. botanisch Gesell. 1888, 127.

THE author attributes the absence of nitrates in forest trees to the lack of these substances in the soil. Numerous analyses of forest soils, peat moors, of waters from moors, and of springs and brooks emanating from wooded mountains, demonstrate the total absence or the presence of only extremely small quantities of nitrates. From this it is concluded that there are not nitrifying organisms in forest and peaty soils, and that conditions are unfavourable in soils containing only vegetable humus. The decomposition of the nitrogenous plant constituents seems in such cases to end with the formation of ammonia, from which it is inferred that forest trees are only capable of taking up their nitrogenous nutrition in the form of ammonium salts or amides.—D. A. L.

Indian Wheat. T. Dietrich. Landw. Versuchsstat. 35, 309—318.

THREE hard varieties, 1—3, four soft, 4—7, and some other samples, were examined with the following results. The

hard wheats yielded a good gluten, the gluten from the soft varieties was not so good. The albuminoids are higher in the hard than in the soft varieties, but nevertheless the percentage in the latter is nearly equal to the percentages obtained in similar wheats cultivated in Germany.

Detection of Nitrates in Soils. Kreusler. Landw. Jahrbuch, 1888.

See under XXIII., page 306.

Humus Substances of Arable and Peaty Soils. C. G. Eggertz. Bied. Cent. 18, 75—80.

The study of previous work on this subject has led the author to infer that humic and ulmic acids as obtainable from carbohydrates, &c., by the action of acids, do not exist ready formed in peat or similar decomposing matter, but that they are products of laboratory reactions. He also considers as doubtful the existence of the indifferent and insoluble substances ulmin and humin. Crenic and apocrenic acids are, however, regarded by him as existing as distinct compounds, although their composition is not definitely decided.

From the author's experiments it is shown that the products of the decomposition of vegetable matter consist of insoluble indifferent bodies, and soluble acids, the latter being of greatest interest, have been carefully investigated by the author.

The substances obtained from the decomposing matter direct, or from soil previously extracted with dilute hydrochloric acid, by extracting them with ammonia or potash, and subsequently precipitating with acid, are called by the author "mullkörper," to distinguish them from the "humuskörper" obtained from carbohydrates, &c. by the action of acids.

The mull and humus substances have many reactions in common:—They are alike soluble in water, alkalis, in ammonium carbonate, oxalate and phosphate, and in sodium and potassium carbonates, but are insoluble in acids, in ammonium chloride, sulphate and nitrate, and in potassium sulphate and phosphate. Their alkaline solutions are precipitated by most acids, but not by carbonic or boric. The calcium compounds are insoluble in water and alkalis, but dissolve to some extent in ammonium chloride, better in nitrate, and better still in sulphate; they also dissolve in ammonium sulphate without precipitation of calcium phosphate; they are, however, decomposed by ammonium oxalate and carbonate, also by sodium and potassium sulphate, with the formation of soluble alkali compounds. One great difference has been observed by the author: the ammoniacal solution of mull substances leaves, on evaporation over the water-bath, a residue perfectly soluble in cold

water: humus substances under similar circumstances leave a residue almost perfectly insoluble in that medium.

The author concludes from his experiments that the mull substances contain besides carbon, hydrogen, nitrogen, and oxygen, other elements, such as sulphur, iron, phosphorus, combined in the organic atomic complex. The composition of 13 of the samples analysed varied as follows:—

C, 40.86–56.18; H, 4.33–6.63; O, 25.09–37.98;

N, 2.59–6.43; SiO_2 , 0.37–10.47; P, 0.15–7.58;

S, 0.55–2.09; Al_2O_3 , Fe_2O_3 , 0.38–3.90.

Both mull and humus substances contain ash constituents which can scarcely be regarded as mere inorganic impurities, inasmuch as such impurities, when added, can be removed with comparative facility by washing. Besides the nitrogen present as ammonium mull salts, mull substances contain nitrogen which is not removed by repeated solution in alkali and precipitation with acid, although the mull substance by such treatment itself undergoes partial decomposition each time, which extends not only to the inorganic, but also to the organic matter, some of the latter becoming more soluble in acids. Experiments were made with eight samples of mull substances containing at the outset from 5.8 to 10.7 per cent. of nitrogen, and at the termination from 2.12 to 5.30 per cent. was retained in combination. Humus substances from starch or pure cellulose form soluble ammonium salts with ammonia, which are decomposed in the usual way by hydrochloric acid, but if they be exposed to a temperature of 110°C ., or if dry humic acid be treated with gaseous ammonia, then some of the nitrogen becomes combined with the organic matter. The same thing occurs when mull substance is treated with ammonia. Sulphur, iron, and phosphorus, are also shown to be integral constituents of the organic atomic complex of mull substances. The first two can only be detected after decomposing the mull substance, whilst the presence of the latter element cannot be attributed to adhering phosphoric acid, inasmuch as neither mull nor humus substances absorb that acid.

Silica is probably present as ammonium silicate, and any alkalis or alkaline earths present may be regarded as impurities.

On dialysing a sample of mull substance, organic as well as inorganic matter diffused, the former, after diffusing, being of different composition to that of the mull substance itself. With reference to the analyses, the author points out that dilute acids extract larger quantities of some constituents from the soil than strong acids do from the ignited soil; this is the case with silica and may happen with small quantities of potash, lime and magnesia. Partial ignition so as just to char the organic matter is objectionable, as constituents of the soil become soluble which were not previously directly assimilable by plants. The author finds even with phosphoric acid the amount soluble in dilute acid is increased by partial ignition. Roots can only assimilate directly those proportions of the plant foods in the soil which are extracted by cold dilute about 4 per cent. hydrochloric acid, and in most cases these quantities are too great and require to be divided by 2 or 3 if the true amount of assimilable constituents is to be ascertained, since hydrochloric acid, however dilute, can always dissolve more of these substances than the weak root-acids. A soil extracted with 4 per cent. hydrochloric acid would hence be quite sterile, although analysis might indicate the presence of plenty of plant nutrition. In fact those constituents of the soil which are in organic combination only become assimilable by the aid of oxidation; and in the author's opinion the constituents derived from the oxidation of mull substances are more important as a natural source of nutrition for cultivated plants than the mineral phosphates and silicates. Oats, which require relatively small quantities of mineral matter, can exist on the matter rendered assimilable during the oxidation of one season. Ordinary modes of working the land aid this oxidation; the favourable action of ammonium salts may in part be attributed to the mull substances being partially decomposed by them and so becoming more susceptible to oxidation. Lime would set free ammonia, which would then act as just described, and its favourable action can be, in part, explained in this manner.—D. A. L.

Onions as a Field-Crop in Australia. R. W. E. Macivor. Chem. Centr. 1888, 638.

Onions were cultivated in some districts in Australia; the harvest soon began to fall off, but was restored to previous abundance by dressing with ammonium sulphate, blood meal, superphosphate, and potash. Superphosphate alone exerted only a slight action. The onions contained, per cent., 89.48 of water, 10.10 of combustible matter, 0.237 of nitrogen, and 0.42 of ash. An average harvest of eight tons removes from the soil in lb. per acre—

PATENTS.

Improvements in the Process of Manufacturing Bicalcareous Phosphate, called Precipitated Phosphate. G. C. Dymond, Liverpool. From C. E. D. Winessinger, Brussels, Belgium. Eng. Pat. 17,945, December 8, 1888. 6d.

See under VII., page 284.

An Improved Process for Desiccating Blood and other analogous Substances. W. Barnsdale, Auckland, New Zealand. Eng. Pat. 18,429, December 17, 1888. 6d.

Blood, fish, or other animal matter is boiled by a steam coil, and passes down an inclined gutter between the spikes of a "masticator" or disintegrating roller, and thence between a pair of squeezing rollers, by which the liquid is expressed. The pressed solids are then spread on trays and dried in a special desiccating chamber heated by a steam coil and also by circulation of the furnace gases.

—J. M. H. M.

Improved Method of Manufacturing Nitrogenous Fertilisers. P. M. Justice, London. From W. J. Williams, Camden, New Jersey, U.S.A. Eng. Pat. 18,906, December 27, 1888. 4d.

Wool waste, hair, blood, tankage, or other nitrogenous matters are treated with sulphuric acid of 50° to 60° . Calcined and pulverised phosphate of iron or phosphate of alumina, or a mixture of both, is mixed with water, and the mixture added to the sulphuric acid and nitrogenous matter. The mixture is allowed to dry below 180°F . The quantity of water used should be just sufficient to allow the mass to set or harden on drying.—J. M. H. M.

XVI.—SUGAR, STARCH, GUM, Etc.

Improvements in the Manufacture of Starch, Dextrin, and Glucose. Dingl. Polyt. J. 271, 185–189; 329–336 and 363–374.

Glucose from Jerusalem Artichoke.—The composition of the artichoke is given by Petermann-Gembloux (*Revue Univer. de la dist.* 1886) as follows:—

	Per Cent.
Water.....	77.68
Carbohydrates convertible into sugar	14.33
Other carbohydrates.....	5.37
Fat	0.18
Protein.....	1.35
Ash	1.10
Total nitrogen	0.22
True albuminoids	0.79

Champy & Fils (Ger. Pat. 35,825 of 1885) treat the juice of the artichoke, or the tubers cut in pieces, at the boiling temperature with gaseous sulphurous acid in a series of communicating vessels. The levulin and inulin contained

in the juice are thus converted into glucose, and the solution is at the same time decolourised. The sulphurous acid is then removed by a current of steam. In case solid glucose is required the small quantity of sulphuric acid formed by oxidation from sulphurous acid is removed by means of barium carbonate.

M. Boudonnoir and G. Forêt have designed an apparatus for the preparation of sugar from starch-containing substances (Ger. Pat. 12,519 of 1887). The apparatus is similar to the diffusion battery used in beet-sugar manufacture, and consists of a series of extraction vessels fitted with false bottoms, with raised heaters between them. These consist of cylinders in which are set conical globes. Inside the globes are steam coils by means of which the fluid may be heated and caused to rise in the tube at top. Very dilute sulphuric, oxalic, or hydrochloric acid circulates over the starchy material, such as peeled maize, rice, rye, barley, oats, &c. contained in the extraction vessels, and converts the starch into glucose without changing the original shape of the grains. The exhausted materials are said to contain the bulk of the nitrogenous bodies originally present. The acid extract is worked up for glucose in the usual manner.

A. Schumann has patented a process for the manufacture of dextrin free from sugar, and similar in its properties to gum-arabic, and to be used as a substitute for it. (Ger. Pat. 41,931 of 1886, and 43,146 of 1887.)

Starch is mixed to a thick cream with cold water and treated with 1 per cent. of its weight of sulphuric, hydrochloric, or nitric acid. After 24 hours the mixture is washed free from acid. The prepared starch is either dried or again mixed with water to a cream, and heated in an oil-bath or by means of superheated steam to 160–170° C. till all the starch is converted into the soluble form. The solution is then refined and evaporated to dryness or to any desired consistency.—H. T. P.

The Estimation of Starch and Sugar in Feeding Materials.

E. F. Ladd. Amer. Chem. J. 10, 49.

Five grms. of the material to be examined are washed on a filter with distilled water till the washings measure 200 cc. The residue is dried and serves for the starch estimation. In the filtrate (10 cc.) the sugar is determined by Fehling's solution. Another portion is inverted by heating on the water-bath for half an hour with hydrochloric acid, neutralised with sodium carbonate, and "Fehlingised." The increased reduction represents substances soluble in water inverted by hydrochloric acid.

In the dried residue from above the starch is estimated. It is heated in an Erlenmeyer flask of 250 cc. capacity with 150 cc. of water and 5 cc. of strong hydrochloric acid for 12 hours at 100° C. on the water-bath. The flask is fitted with a cork and long glass tube to act as condenser. After heating it is allowed to stand 12 hours longer, filtered, rendered slightly alkaline with carbonate of soda, diluted to 200 cc., and "Fehlingised."—H. T. P.

The Composition of Iodide of Starch.

F. Seyfert. Zeits. f. angew. Chem. 1888, 15.

Assuming the starch molecule to consist of $C_{24}H_{40}O_{20}$, the formula of iodide of starch is $(C_{24}H_{40}O_{20})_6I_7$, or a multiple of it.

The author likewise describes the following rapid method of estimating starch in commercial starch powders: 1 gm. of starch is treated with 100–150 cc. of hot water and heated on the water-bath at 100° C. till perfectly gelatinised. The paste is washed into a 500 cc. flask and 50 cc. of an iodine solution, containing but little potassium iodide and about 12–13 grms. of iodine per litre, added, as well as 20 cc. of strong hydrochloric acid. The solution is diluted to 500 cc., well shaken, and allowed to settle. Two lots of 50–100 cc. are then pipetted off and titrated with sodium thiosulphate. Iodide of starch, according to the above formula, contains 22.865 per cent. of iodine. The iodine absorbed by the starch, multiplied by 4.37, will therefore give the quantity of starch.

Reference is made to the researches of F. Mylius (Zeits. f. phys. Chem. 11, 306) (see this Journal, 1888, 397) which assign to iodide of starch the formula $(C_{24}H_{40}O_{20})_6I_{11}$. This compound contains 24.489 per cent. iodine.—H. T. P.

Invert Sugar.

E. Jungfleisch and L. Grimbart. Compt. Rend. 108, 141–146.

The rotatory power of pure levulose varies considerably from the value obtained by calculation from the optical activity of invert sugar, considered as a mixture of equal parts of levulose and dextrose. This is shown in the following table:—

Temperature.....	0	5	10	14	20
(α) _D for pure levulose.	101.22	98.12	95.62	93.38	90.02
(α) _D for the levulose of invert sugar...	108.54	105.34	102.14	99.58	95.74

The authors ascribe these differences to a peculiar modifying influence of the strong acids on levulose. Dextrose added to a solution of levulose, in quantity equal to the levulose present, does not modify its specific rotatory power. Acids, however, have a powerful influence. A solution of pure levulose with 10 per cent. of HCl gave, at 12° C., (α)_D = –94.66°; after heating for half an hour to 68° C. with 5 per cent. of hydrochloric acid, (α)_D = –96.78°. Sulphuric acid used in a similar manner yielded (α)_D = –99.78°. The readings were not affected by neutralisation of the acids. This action of strong acids is exerted instantly and even at ordinary temperatures. Hydrochloric acid added in the cold to a levulose solution gave (α)_D = –96.50°. Oxalic acid has a similar action on heating. Acetic and formic acids employed at the rate of 5–10 per cent. have no influence on the specific rotatory power of pure levulose. The optical activity of dextrose is not influenced under any of the above conditions. Cane sugar inverted by Clerget's method (heating with one-tenth of HCl to 68° C. for 10 minutes) gives as the value for levulose at 12° C. (α)_D = –101.30°; when only one-twentieth of its bulk of HCl is used, and the time of heating prolonged to 30 minutes, (α)_D = –96.52°. This number corresponds very nearly with the value for pure levulose under the same conditions, (α)_D = –96.78°. When cane sugar is inverted by heating with 5–10 per cent. of formic or acetic acid to 100° C., the levulose of the resulting invert sugar possesses the specific rotatory power of pure levulose. Thus under conditions where pure levulose gave (α)_D = –94.66°, the levulose of invert sugar gave (α)_D = –94.75° (inverted by 5 per cent. acetic acid, 30 mins. at 100° C.), (α)_D = –94.48° (5 per cent. acetic acid, 60 mins. at 100° C.), (α)_D = –94.00° (10 per cent. acetic acid, 60 mins. at 100° C.), (α)_D = –94.80° (5 per cent. of formic acid, 30 mins. at 100° C.). On addition of HCl to the solutions thus inverted the readings were increased as before.

The authors come to the conclusion that:—

1. Strong acids modify the rotatory power of levulose more or less according to circumstances.
2. The levulose of invert sugar made by the ordinary process is not identical with pure crystallised levulose, but is a modification of it.—H. T. P.

The Extraction of Sorbite.

C. Vincent and Delachanal. Compt. Rend. 108, 147–148.

The authors indicate several methods by which an increased yield of sorbite may be obtained from the service-berry. Sulphuric acid and alcohol are employed to eliminate the potash and lime (which hinder the crystallisation of the sorbite) from the extract, in the shape of insoluble sulphates.

The fermented juice of the service is concentrated in vacuo to a third of its volume. A portion (10 grms.) is ignited with the addition of excess of sulphuric acid, and a determination of sulphuric acid made in the residual ash.

The quantity of sulphuric acid necessary to combine with the bases present is thus known. The calculated quantity of sulphuric acid, diluted with its own volume of water, is

added to the remainder of the extract, and then two volumes of alcohol. The precipitate is filtered off, the alcohol removed from the filtrate by distillation, and a slight excess of barium hydrate added. The clear liquid is treated with basic acetate of lead, followed by sulphuretted hydrogen; it is then concentrated in vacuo. The syrup yields a large amount of sorbite, but slowly. This slowness of separation is due to the influence of the barium salt of a certain acid or acids present in the extract, which are not precipitated by basic acetate of lead or the alkaline earths, are soluble in water, but nearly insoluble in alcohol. On this latter observation a method of separation is based. The liquid, treated as above, is exactly saturated with barium hydrate and evaporated in vacuo to a thick syrup. The syrup is extracted with boiling alcohol of 95 per cent., which dissolves out the sorbite only. By the evaporation of the alcohol a syrup is obtained, which, in the course of a few days, deposits an abundant crop of sorbite in long needles.

Mémier has shown that sorbite forms, with benzaldehyde, an acetal insoluble in water. A method for the determination of sorbite may be based on this fact. The authors proceed as follows:—The juice of the service, concentrated to a third of its volume in vacuo, is treated with basic acetate of lead in excess, followed by sulphuretted hydrogen, and then evaporated in vacuo to a thick syrup. The syrup is treated with its own weight of sulphuric acid (50 per cent.) and 80 per cent. of its own weight of benzaldehyde. The mixture soon solidifies, owing to the formation of the acetal. After 24 hours the mass is powdered and washed with water by decantation. The weight of the washed and dried precipitate is a measure of the quantity of sorbite present in the substance. The sorbite may be obtained from it thus:—The precipitate is heated with water containing a few tenths of sulphuric acid and benzaldehyde. After completion of the reaction, the aldehyde is distilled off in a current of steam. The residue is saturated with barium hydrate, filtered, and the excess of barium exactly precipitated by sulphuric acid. After cooling, the liquid is agitated with ether to remove the small quantity of benzoic acid formed by oxidation from the benzaldehyde. The liquid is then evaporated in vacuo and decolourised by means of a little animal charcoal. In a few days it deposits a considerable amount of sorbite in the shape of long brilliant needles.—H. T. P.

On Sorbite and its Presence in Fruit of the Family of Rosaceae. C. Vincent and Delachanal. *Compt. Rend.* 108, 354—356.

Sorbitol is contained in pears, apples, and Brittany cider. It is best separated and purified by means of the compound it forms with benzaldehyde. The specific rotatory power of pure sorbite is -1.73 for the ray D, at 15° . It is, therefore, twelve times as active as mannite in turning polarised light. Oxidised with potassium permanganate an acid and a reducing sugar are formed. Nitrosorbite is obtained by the action of fuming nitric acid and sulphuric acid in the cold. It is an oily liquid which burns when brought in contact with a fuse and explodes violently by concussion.—A. R.

Extraction of Raffinose from Raw Sugar and Raw Sugar Syrup. G. Burkhard. *Neue Zeits. f. Rübenzuck. Ind.* 1888, 16.

The raw sugar or raw sugar syrup dried with sawdust is extracted with methyl alcohol. The methyl alcohol is distilled off, the residue diluted with water and boiled for 20 minutes with sufficient strontium hydroxide to cause the separation of granular raffinose-saccharate, and yet to leave a visible excess of the hydroxide on the surface. The precipitate is separated, washed with boiling strontium solution, and decomposed by means of carbonic acid. The solution is evaporated down, and on warming with alcohol raffinose crystallises out.—D. A. L.

Compounds of Phenylhydrazine with the Sugars. E. Fischer. *Ber.* 22, 87—97. (Compare this Journal, 1888.)

The sugars yield with phenylhydrazine compounds known as "osazones," and these decompose with strong hydrochloric acid into oxidation products and phenylhydrazine. Thus phenylglucosazone yields a compound—

and phenylhydrazine. The author has given to these oxidation products the name "Osone." The above compound is therefore "glucosone." These bodies react with the primary and secondary hydrazines and *o*-diamines like glyoxal, and are reduced with zinc dust and acetic acid to levulose. This reaction is generally applicable, and has been studied by the author in the case of glucosazone, galactosazone, sorbosazone, lactosazone, maltosazone, α - and β -arabosazone, formosazone, arabinosazone, and the osazone of isodulcitol. Erythrosazone, glycerosazone, and glyoxal-phenylsazone act otherwise, and the osazones of the ketone acids are even more stable in presence of strong hydrochloric acid. Glucosone is obtained by adding strong hydrochloric acid to powdered phenylglucosazone at the ordinary temperature. It is shaken and warmed for a short time, and quickly cooled. It is filtered from phenylhydrazine, washed with dilute hydrochloric acid, excess of lead carbonate added to neutralise the acid and precipitate colouring matter. The filtrate is neutralised with baryta, and the osone precipitated with lead hydroxide. The lead is precipitated with sulphuric acid, &c., and the solution of the free glucosone evaporated in vacuo. It forms a solid amorphous mass; reduces Fehling's solution, turns polarised light faintly to the left, and does not ferment. With phenylhydrazine it readily unites to form phenylglucosazone, and with methylphenylhydrazine to form glucosomethylphenylhydrazine, $\text{C}_6\text{H}_5\text{N}(\text{CH}_3)\cdot\text{N}(\text{CH}_3)\cdot\text{C}_6\text{H}_5$. If an excess of methylphenylhydrazine is employed in acetic acid solution methylphenylglucosazone is obtained. It differs from phenylglucosazone by its greater solubility in alcohol and benzene.

The formula for this substance is doubtless—

Glucosone also combines with *o*-tolylenediamine in aqueous solution to form a compound of the formula $\text{C}_{13}\text{H}_{16}\text{N}_4\text{O}_4$. With hydrochloric acid it decomposes, yielding levulinic acid. Reduced with zinc and acetic acid it gives levulose, which with sodium amalgam, yields mannite.—J. B. C.

Synthetic Experiments on the Sugars. E. Fischer and J. Tafel. *Ber.* 22, 97—101.

ACROLEINBROMIDE yields with the alkalis or baryta a sugar, $\text{C}_6\text{H}_{12}\text{O}_6$, which combines with phenylhydrazine, forming the compound α -arabosazone. On reduction with zinc and acetic acid a base is obtained, which, with nitrous acid, gives a non-nitrogenous amorphous product to which the authors give the name of α -arose. α -Arabosazone behaves with conc. hydrochloric acid like glucosazone, and gives an "oson" corresponding to glucosone, and which is therefore called α -arosone. With phenylhydrazine arabosazone is regenerated, and it combines likewise with *o*-tolylene-diamine. Hydrochloric acid converts it into levulinic acid. With zinc dust and acetic acid a sugar is produced, which ferments with yeast, and with the exception of its inactivity on polarised light has all the characteristics of the glucoses. (Compare this Journal, 1888, 128.)—J. B. C.

Acrose from Formaldehyde. E. Fischer and F. Passmore. *Ber.* 22, 359—361.

By the action of lime-water on formaldehyde, a mixture of aldehyde or ketone-alcohols is obtained. One of these compounds combines with phenylhydrazine to form α -arabosazone from which acrose may be prepared. The following is an outline of the method adopted. A 3 per cent. solution of formaldehyde is converted by lime-water into Loew's

formose. The latter compound is treated with phenylhydrazine and acetic acid (50 per cent.) and heated on the water-bath. The product is treated with benzene and ether, and finally with water, which leaves a small residue of aerosazone. This, after recrystallisation, is converted by concentrated hydrochloric acid into the osone, which may be converted into the osazone. It is only in this way that the osazone can be purified. The substance is identical with the compound obtained by the action of phenylhydrazine upon aërose.—J. B. C.

Oxidation of Milk Sugar. E. Fischer and T. Meyer.

Ber. 22, 361—364.

If 1 part of milk sugar dissolved in 7 parts of water be treated with 1 part of bromine at the ordinary temperature, the greater part of the bromine disappears. The excess of bromine is driven off by a current of air, and the hydrobromic acid removed by lead carbonate and silver oxide. The aqueous solution contains the new acid lactobionic acid, which remains as a syrup on evaporating the liquid. If the syrup is triturated with cold glacial acetic acid impurities are removed and lactobionic acid is obtained in the form of a white amorphous mass. It does not reduce Fehling's solution. It is soluble in water, but not in alcohol, ether, or acetic acid. It is split up with dilute mineral acids into galactose and gluconic acid. This decomposition may be expressed as follows:—

—J. B. C.

Mannose. E. Fischer and I. Hirschberger. Ber. 22, 365—376.

MANNITE on oxidation with dilute nitric acid yields mannose. After neutralising the product with carbonate of soda, phenylhydrazine dissolved in acetic acid is added. The phenylhydrazone crystallises out. The compound is recrystallised. The yield is about 10 per cent. of the mannite.

Dissolved in four times its weight of hydrochloric acid (sp. gr. 1.19), phenylhydrazine hydrochloride separates out. The solution contains mannose, which after purification forms a colourless syrup. The yield is about 60 per cent. of the phenylhydrazone. The syrup may be precipitated by ether in the form of a white flocculent substance; but has not yet been crystallised. Mannose ferments with yeast as readily as dextrose, and may be reduced to mannite with sodium amalgam. It reduces copper solution and turns the plane of polarisation to the right. The specific rotatory power is $(\alpha)_D = 192.96$. Tested by Fehling's solution 1 cc. is equivalent to 3.307 mgrm. of mannose. Of all the different sugar-producing substances tested, the authors only succeeded in confirming the presence of mannose first discovered by Tollens and Gans in salep gum.

Mannose when heated in aqueous solution to 140 decomposes, yielding furfural; with concentrated hydrochloric acid, levulinic acid is formed.

Like other sugars it combines with hydrocyanic acid. Fifty grms. of mannose, 250 grms. of water, and 18 cc. of anhydrous hydrocyanic acid are mixed together in a stoppered flask and left at the ordinary temperature. A solid compound separates, which is the amide of mannose carboxylic acid. The solution contains the ammonium salt of the acid.

The latter readily forms salts. The free acid immediately passes into the lactone—a crystalline compound of the formula $\text{C}_7\text{H}_{12}\text{O}_7$. Mannose carboxylic acid reduced with hydriodic acid and phosphorus yields an oily liquid with acid properties having the composition of heptylic acid.

Mannose combines with phenylhydrazine to form an azone, which is identical with glucosazone from dextrose.

From the various reactions which mannose undergoes it is considered as an aldehyde of a constitution similar to

dextrose. The difference is due to geometric isomerism, there being four asymmetric carbon atoms in the formula for dextrose.

This explains the formation of the osazone in the case of both isomerides. It will therefore be best represented by the formula—

—J. B. C.

The Formation of Carbohydrates from Formaldehyde. O. Loew. Ber. 22, 470—478.

THE condensation of formaldehyde to formose depends upon the strength of the base, and the concentration of the formaldehyde solution. If the base is either too strong (caustic soda) or too weak (magnesia) no condensation occurs. Lime and oxide of lead produce condensation, as also metallic lead. The fact that bases affect condensation and not acids may be ascribed to the formation of intermediate compounds with the bases. A compound of this character is formed with lead oxide. In spite of numerous trials with a variety of bases no natural carbohydrate has been detected in crude formose. The author finds the best yield of fermentable sugar may be attained as follows:—10 grms. of formaldehyde are dissolved in 4 litres of water, 0.5 gm. of magnesia and 2—3 grms. of magnesium sulphate added, and the solution heated with 350—400 grms. of granulated lead to 60° for 12 hours.

The liquid may be evaporated at 50° to a syrup extracted with 80 per cent. alcohol, and the sugar precipitated with ether. This process is repeated and the precipitated formose redissolved in water and evaporated. The residual syrup has an intensely sweet taste and reduces Fehling's solution. It ferments readily with yeast, giving alcohol. The author considers formose to be allied more closely to levulose than to dextrose, as, like the former, it is decomposed by a 7.5 per cent. solution of hydrochloric acid. It yields a glucosazone similar to Fischer's phenyl glucosazone. From the osazone the sugar may be regenerated. The author considers this a distinct substance and calls it "methose."

—J. B. C.

Notes on Formose. O. Loew. Ber. 22, 478—482.

FISCHER has found that formose is not a simple substance. The author confirms this, and finds that from it three osazones may be prepared:—

1. An osazone readily soluble in ether, called formosazone. It is present to the extent of 75—82 per cent.
2. 16—12 per cent. of an osazone with difficulty soluble in ether, readily soluble in alcohol.
3. 3—4 per cent. of an osazone insoluble in ether, with difficulty in cold alcohol.

In preparing formose in very dilute solutions, with thin milk of lime in place of the thick paste, and using a 1 per cent. solution of formaldehyde, the amount of osazone decreases to 48—53 per cent. Formose, which name the author retains for the principal product of the reaction, is decomposed with hydrochloric acid, yielding furfural, and humus substances, but no levulinic acid. It undergoes the lactic but not the alcoholic fermentation. It is more rapidly attacked by bromine than levulose, but less rapidly than dextrose. It does not yield on oxidation an acid with six carbon atoms, and on this account the author regards it as a ketone alcohol, like levulose and sorbinose.

The rest of the paper is devoted by the author to vindicating his claim to be the first discoverer of artificial sugar.

—J. B. C.

PATENTS.

Improvements in and connected with Defecators or Eliminators for Saccharine and other Liquids. R. Harvey, Glasgow. From T. S. Cornish, Demerara. Eng. Pat. 6030, April 23, 1888. *Sd.*

This invention has reference to a modified form of pan for evaporating sugar or other solutions either in vacuo or at atmospheric pressure. The pan is of elongated rectangular shape in its horizontal section. Through one end of this pan passes an iron pipe capable of revolving on its axis. The vertical section of this pipe is of a B shape, thus forming two tubes in one. Steam is supplied into the upper tube, and after passing through a number of smaller tubes which branch off therefrom, returns into the lower tube, from which the condensed water escapes. The branch tubes pass through the length of the pan at an angle slightly inclined to the horizontal, dipping away from B, and then return, with a similar downward inclination, to the lower tube of the B. Thus the whole system of pipes through which the steam circulates is capable of revolving on B as an axis, and can be submerged in the liquor or revolved out of it at will. Moreover the part of the pan about B is the hottest part of the pan, and is the deepest, the other end shallowing off towards a lip, over which the scum escapes. For drawing off the clear liquor, there is another short pipe attached to the bottom of the pan by a swivel motion, so that the mouth of the outlet pipe may be lowered or raised to any particular level from which it is desired to draw off the liquor. Full drawings are given in illustration of the invention.—A. J. K.

Improvements in the Manufacture of Starch. H. Kiel, Bremen, Germany, and R. Stoltenhoff, London. Eng. Pat. 6778, May 7, 1888. *6d.*

In this process the starch-bearing grain is acted upon by caustic lye in vessels from which the air has been exhausted, and the vessels are arranged in series, the lye passing from one to the other in regular order. The cells of the grains are burst by the action of the vacuum, so that the lye is

able to operate more readily on their contents. It is also stated that by the absence of air and of carbonic acid contained therein, a re-precipitation of gluten, generation of fungi, and fermentation are practically prevented. The treatment is finished in about six hours. From the saturated lye the protein is precipitated by an acid, preferably by carbonic acid, and the precipitate contains about 90 per cent. of pure protein.—A. J. K.

Process for Manufacturing Crystallised Maltose. O. Lenz, Berlin, Germany. Eng. Pat. 75, January 2, 1889. *4d.*

Pure potato-starch or other starch is dissolved in water in proportion of 1 to 4, under a high pressure, and cooled at once to 40° C. 20 per cent. of malt is now thrown in, and the whole is cooled down to 20° C. At this point the mixture is well agitated and allowed to stand. After three hours all the starch has disappeared, and after 24 to 36 hours the whole of the dextrin is converted into maltose. The solution is now filtered mechanically, heated to 70°, and again filtered mechanically. Subsequently it is diluted and filtered through bone black. The filtered syrup is concentrated by evaporation, and finally crystallised with addition of a few crystals of pure maltose, previously prepared. The essential point in the process is the low temperature at which the conversion takes place.—A. J. K.

The extract from 15 wheat malts, calculated for 10 per cent. of water, varied from 71.40 to 76.0 per cent., whereas average barley malt contains 66.1 per cent. of extract. Comparative experiments on the fermenting of wheat and barley malt showed that from 100 grms. of wheat-malt 60.08 grms. of starch had been converted to alcohol, whereas from the same quantity of barley-malt only 52.03 grms. of starch had been converted to alcohol.—J. W. L.

Recent Advances in Brewing. Dingl. Polyt. J. 271, 375—383.

The Causes affecting the Consistency of the Endosperm of Barley. T. Adametz. (*Allgem. Brauer- und Hopfenzeit.* 28, 2182).—Glassy and steely barleys are distinguished by a close formation of the endosperm, and narrower spaces between the starch cells, while in mealy corns the texture is more open and consequently more air is contained in them. Sections of the endosperm of mealy corns, immersed in water, appear darker and less transparent than those of steely corns. On adding alcohol, far more air is expelled from mealy than from steely barley. Steely barley also contains a larger proportion of nitrogenous bodies. This factor is, however, not of much importance, since it depends not only on the mealy or steely condition of the grain, but also on soil, climate, manure, and the species of barley.

There is, further, a connexion between the shape of the corns and the percentage of nitrogen. The broader and

rounder the corns, the less nitrogen they contain; the specific gravity of the barley rises at the same time, and the heaviest barley contains least nitrogen. The nitrogen also diminishes with the increase of the absolute weight of the grains. Flat-grained barley also yields more chaff than round-grained barley.

The Bitter and Resinous Constituents of the Hop. Hayduck. (*Wochenchr. f. Brauer.* 5, 937.) See this Journal, 1889, 129—130.—H. T. P.

Effect of Drying on the Composition of the Malt, Wort, and Beer. P. Matz. (*Allgem. Brau- u. Hopfenzeit.* 1888, 2043—2044.

The barley employed in these experiments was white, thin-husked, with full and floury grains; 97.3 per cent. germinated and 1,000 grains weighed 49.32 grms.; it contained per cent. H_2O , 13.1; N, 1.29; albuminoids, 8.07; P_2O_5 , 0.83; ash, 2.65. A few grains were specked, but otherwise it was an excellent malting barley. On the floor the germinating average increased 2.7 per cent.; the temperature of the steeping water was 75° C.; of the steeping chamber, 125° C.; the steeping lasted 100 hours. It was 9 days 10 to 17 hours on the floors, the highest temperature being 12.5° C. The growth was long and uniform and the odour good. The effects of various modes of drying are seen in the following tables:—

Conditions of Drying.	Malt.					Wort.

Condition of the worts is also described.—D. A. L.

The Prevention of Foaming Fermentations. Honig. Zeits. f. Spiritusind. 11, 135.

THE author recommends the addition of a small quantity of mineral lubricating oil (25 cc. per 2,200 litres) to the potato mash at 50° C. and previous to the addition of the larger quantity of malt.

For the same purpose, *Christek* (*ibid.* 11, 203) strews a mixture of 10 kilos. of oat-malt grist with 0.5 kilos. of sulphuric acid previously diluted with a few litres of water, over the foaming tun. The foam completely disappears in 5–10 minutes, and active fermentation sets in, accompanied by rapid evolution of carbonic acid. It is necessary to repeat the treatment several times at intervals of 1–2 hours. After several repetitions the main fermentation proceeds normally, followed by an active after-fermentation. The spirit and wash are satisfactory in every way.—H. T. P.

The Influence of the Concentration of the Nutritive Media on the Propagation of Alcoholic Ferments and on Attenuation.

THIS question has been examined by *J. Archleb*; and *Windisch* quotes the results obtained in the *Zeits. f. Spiritusind.* 11, 243 and 248. The experiments were made with maltose solutions containing from 1–25 per cent. The temperature in all cases was the same, likewise the quantity of pitching yeast. After fermentation the alcohol and yeast were determined. The author draws the following conclusions from his results:—

1. The increase of yeast in nutritive media, containing from 1 per cent. to 25 per cent. extract, is not proportional to the strength of the solutions.
2. Certain concentrations seem to favourably influence the multiplication of the yeast; and several maxima can be found.
3. In solutions containing from 1–5 per cent. extract the yeast crop increases with the concentration. In a 5 per cent. solution the yeast is multiplied 6.6 times.
4. Between concentrations of 5–10 per cent. only a slight increase of yeast reproduction takes place. In a 10 per cent. solution it is 7.37 times. At 7 per cent. concentration it is only multiplied 5.96 times.
5. In media containing 10–14 per cent. extract the reproduction of yeast is most active, and rises rapidly from 7.37 to 14.2 times the pitching yeast, in 14 per cent. extract solutions.
6. The maximum of reproduction takes place in a 14 per cent. medium.
7. Between concentrations of 14–19 per cent. the amount of yeast production again falls, and in a 19 per cent. medium is 10.1 times that of pitching yeast.
8. Between 19–25 per cent. extract there is an increased yeast crop. At 25 per cent. the yeast is multiplied 12.53 times; at 24 per cent. extract, 12.84 times.
9. It is probable that in stronger worts the reproduction of yeast will be much less; for in such media diffusion can only take place slowly. An extract of 36 per cent. is probably the limit.

From these results it follows that in the manufacture of pressed yeast, the most suitable wort concentration is 14 per cent. The results also explain why a strength of 10–11 per cent. is best for the production of sound beers. For at these concentrations the yeast reproduction is greatest and, consequently, the bulk of those nitrogenous bodies which influence the stability of beer are removed.

Caution is recommended in the use of artificial wash as a feeding material (*Zeits. f. Spiritusind.* 11, 144) owing to the fact that out of 70 cattle which were fed with hot dilute wash, nine grew ill after the third day and one died. An examination of the dead animal indicated alcoholic poisoning. It is strongly insisted upon that the wash must only be used fresh, and that as high a temperature as possible should be employed during the mashing process, followed by boiling. The malt added must also be restricted to its lowest limit. If not employed at once it should be kept at a temperature of 56°–63° C., or at least boiled before use. The cleanliness of all the apparatus is also of extreme importance. When these precautions are attended to, the use of artificial wash or sweet mash is quite without danger. The amount of wash given to cattle should not exceed a quantity equal to 15 kilos. potatoes per 500 kilos. live weight.—H. T. P.

The Duty-Free use of Spirit for Technical Purposes.

THIS question was discussed before the German Federal Council on June 21st, 1888. The following decisions were arrived at.

40 grms. of oil of lavender or 60 grms. of oil of rosemary may be added to each litre of the general denaturising material, by those who are licensed to make it. In particular cases 5 per cent. of wood spirit alone may be used. The employment of animal oil, turpentine, sulphuric ether, and shellac for denaturising is permitted in certain instances. For the manufacture of vinegar, spirit may be denaturised by means of 200 per cent. of 3 per cent. vinegar, or 30 per cent. of vinegar containing 6 per cent. of acetic acid, 70 per cent. of water, and 100 per cent. of beer. 100 per cent. of wine may be substituted for the beer.

The general denaturising agents must conform to the following rules:—

(1.) Wood spirit. It must be colourless or only slightly yellow. On distilling 100 measures at 760 mm. pressure, 90 volumes must pass over at 75° C. No sensible turbidity must be produced on dilution with water. The amount of acetone must exceed 30 per cent. It must contain at least 1 per cent., but not more than 1.5 per cent. of bodies, decolourising bromine.

(2.) Pyridine bases. They should be colourless or only slightly yellow. The water must not exceed 10 per cent. On distilling 100 volumes at 760 mm. pressure, at least 90 volumes should pass over under 140° C. No appreciable turbidity must be caused by dilution with water, and the sample should contain no ammonia. The analytical examination of the various denaturising materials is then described in detail.—H. T. P.

The Microscopic Examination of Yeast. P. Lindner. Wochenschr. f. Brauerei 5, 450.

THE author recommends the treatment of the yeast, previous to examination, with potash or soda solution of about normal strength. By this means particles of resin and nitrogenous matter are dissolved, and conglomerations of yeast cells separated, while cells of other yeasts, especially *Pediococcus*, are unchanged. The author points out that mistakes are often made owing to the crushing of yeast cells under the cover-glass. The protoplasm is divided into small particles, which vibrate, and look very similar to small bacteria. The motion is, however, not progressive, but a lateral one, the so-called Brownian movement. The author further points out that errors frequently occur in testing for dead cells by means of an aniline colour, owing to the use of too strong solutions of dye, or owing to the addition of too little colour to a given amount of yeast. It is best to use a weak solution of the staining agent, and to add so much yeast that about 50 cells appear in each field.—H. T. P.

PATENTS.

An Improved Process of and Plant for Treating Cereals, Starchy or Farinaceous Substances for making Alcohol, Vinegar, and other like Products. E. Manbré, Garston. Eng. Pat. 3510, March 7, 1888. 8d.

IN this process the cereals or other starchy substances are first crushed between rollers, and the crushed meal passed through a convenient sieve, by which means from 15 to 20 per cent. of the bran is separated. The meal is then ground into flour and conveyed to a closed wooden mash-tun, where a sufficiency of water as well as a mixture of sulphuric, sulphurous, and nitric acids are added in the proper proportions. Steam is then turned on and the mixture kept boiling for about half an hour. It is then rapidly run into a high-pressure converter, where a temperature of 350° F. is gradually reached; as soon as conversion is complete the mixture is run off into a wooden receiver and neutralised, then filtered, cooled, and conveyed to the fermenting tubs, and yeast together with a mixture of cream of tartar and phosphate of potassium added. When the fermentation has ceased the wort so obtained is passed through an ordinary Coffey's still combined with a rectifier,

whereby continuous distillation and rectification are carried on in the one operation. For the production of vinegar a similar process of saccharification is adopted, yeast alone is, however, added at the fermenting stage, different earthy phosphates being added during the oxidation of the alcohol and its conversion into vinegar.—J. H.

An Improved Apparatus for ascertaining the Degree of Maceration of Barley when Malting. K. Berneruther and W. Kumpfmiller, Munich, Bavaria. Eng. Pat. 4616, March 26, 1888. 8d.

This apparatus consists of a small vessel formed of perforated sheet metal, the top and bottom being fitted with moveable covers of a conical or pyramidal form. A moveable rod is provided to screw into the upper cover and a handle is fitted to the rod. A certain quantity of barley is placed in the vessel, which can, on account of its form, be readily slipped into the malt in any desirable part and to any depth. When the vessel is withdrawn (the rod and handle being removed) it is carefully weighed, the increase in weight showing the relative amount of water absorbed.

—J. H.

Improvements relating to the Pasteurisation of Beer, Wine, and other Liquids. W. Kuhn, Clermont-Ferrand, France. Eng. Pat. 15,261A, October 23, 1888. 6d.

This invention claims that: 1st. The heating is effected in a uniform manner and without division of the material, so that no part of the beer shall at any moment be raised to a higher temperature than the final temperature at which the operation takes place, in order to obviate the unpleasant flavours imparted to the material by a change in the overheated parts. 2nd. No part of the beer shall remain at a lower temperature than the final degree at which the operation takes place, in order to obviate the ulterior fermentations that would be caused by the ferments which have not been rendered insensible and which are contained in these insufficiently heated fractions. 3rd. The beer is raised to the highest temperature which can be obtained in the shortest time possible, in order to obviate the flavour which the beer receives by exposing it too long to a high temperature. 4th. Nevertheless the heating agent must be of a temperature which differs as little as possible from the final temperature at which the operation takes place, and for this purpose it is necessary to provide for as large a surface of contact as possible between the liquid treated and the heating agent. 5th. The displacement of carbonic acid from one part of the beer to another is obviated in order that the elements which could be decomposed and remained present in the same proportions shall be able to re-constitute the compounds, thereby obviating one of the principal causes of the flavour of pasteurisation. 6th. The employment, as a cooling agent, of incongealable liquid or any other source of artificial cold susceptible of reaching -10° and capable of effecting a sudden decrease of temperature, which facilitates the re-constitution of the compounds.

—J. H.

Improvement in Rice-product and Process for preparing same. E. V. Donelson, Baltimore, U.S.A. Eng. Pat. 15,959, November 5, 1888. 4d.

See under XVIII. A., this page.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

Adulteration of Linseed Meal. E. Eidam. Landwirt. 1888, 475.

It has been noticed that cattle frequently refuse to eat linseed meal; at other times they have sickened or even

died after eating it. On examination some samples of linseed meal were found to contain besides ordinary impurities castor oil and hemp seeds as adulterants. The former contains a strongly poisonous constituent, and would account for the disastrous results referred to. The press residues of castor oil seed are only fit for manuring purposes. The microscopic appearance of the two adulterants is described.—D. A. L.

PATENTS.

The Manufacture of a Carbonated Oxygen Water. The Brin's Oxygen Company and P. B. W. Goble, London. Eng. Pat. 3530, March 7, 1888. 4d.

CARBONATED oxygen water is produced by charging the water with oxygen and aerating it with carbonic acid gas by any suitable means. The receptacles to contain the water must be filled with oxygen gas so as to exclude atmospheric air.—E. E. B.

An Improved Composition and Devices for Facilitating the Use thereof, chiefly Designed for Preserving Animal and Vegetable Substances. H. H. Lake, London. From S. F. Van Choate, Boston, U.S.A. Eng. Pat. 12,774, September 4, 1888. 8d.

This preservative composition consists of equal parts of caustic potash, chloride of potash, oxide of manganese, and chloride of potash with which a mixture of gum tragacanth and hydrogen peroxide may be incorporated to impart adhesiveness. The mixture is placed in conical moulds, of which the bottom and lower part of the sides are perforated, and the moulds then placed in pans of water in the chambers containing the articles to be preserved. The compound dissolves in the water, and when this evaporates the food, &c. becomes impregnated with the preserving vapour. "Partially decayed matter" is almost instantaneously restored to a condition of "absolute freshness" by dipping it into a solution of the compound.—E. E. B.

Improvements in Rice-product and Process for Preparing same. E. V. Donelson, Baltimore, U.S.A. Eng. Pat. 15,959, November 5, 1888. 4d.

THE rice grain is submitted to a moist heat to loosen the outer covering of cellular tissue, and afterwards passed through a pair of ordinary "burr" stones which remove the outer casing without breaking the grain. The grain is now again subjected to a straining process to thoroughly develop the soluble starch, dextrin, and sugar, still without destroying the form of the grains. Immediately on completion of this cooking process the hot grains are suddenly cooled by cold water or a blast of cold air to harden the outside of the grain. The cold grains are now "subjected to the treatment of rolls or mill," and the product dried. The product is wholly soluble, may be kept for any length of time, and is easily handled. It is useful for brewers and as an alimentary substance.—A. J. K.

(B)—SANITARY CHEMISTRY.

Purification of Effluent Waters. Comparative Purifying Effect of Caustic Lime and other Substances. H. Schrieb. Chem. Zeit. 13, 17—18 and 30—31.

IN the former experiments made by the author (this Journal, 1888, 862) the purifying effect of caustic lime alone on the organic matters of effluent waters was determined. The comparative effect of this reagent in conjunction with other substances was now tried, with the following results, representing the amounts of organic matter precipitated by the various reagents.

Purification with :—

—	Lime alone.	Lime and 0·2 Grm. of Siliceous Material per Litre.	Lime and 0·2 Grm. of Water-Glass per Litre.
	Megms. per Litre.	Megms. per Litre.	Megms. per Litre.
1	600	530	602
2	455	485	515
3	610	605	560
4	540	490	533
5	672	705	680
6	1,075	1,250	1,290
Average..	659	678	697

Purification with :—

—	Lime alone.	Lime and 0·2 Grm. of Aluminium Sulphate per Litre.	Lime and 0·2 Grm. of Ferrous Sulphate per Litre.
	Megms. per Litre.	Megms. per Litre.	Megms. per Litre.
7	500	535	545
8	550	530	295
9	210	205	260
10	247	252	220
Average..	342	330	330

Purification with :—

—	Lime alone.	Lime and 0·2 Grm. of Aluminium Sulphate per Litre.	Lime and 0·2 Grm. of Magnesium Sulphate per Litre.
	Megms. per Litre.	Megms. per Litre.	Megms. per Litre.
11	765	787	815
12	475	525	455
13	180	152	123
14	765	712	787
Average..	546	544	545

From these results the conclusion may be drawn that lime alone affects as great a purification as when the other substances named are used in conjunction with it. The author believes this to have been attained thus. The purifying quality of lime is due to the formation of precipitates, which cohering together in flocculent masses, carry down with them other suspended matters. These pre-

cipitates with lime consist of salts of organic acids and proteids. In addition to these precipitates it appears necessary that sulphate or carbonate of lime or both shall be formed in order that the precipitation shall be rapid and effectual, and for this reason the addition of such substances as ferrous and aluminium sulphates have been recommended in addition to the lime. The author however points out that the amount of inorganic sulphates and carbonates already present in the waters are quite sufficient in almost all cases (and he points out here that no general rule for the purification of affluent waters can be given) for the formation of the necessary precipitate to carry down the organic precipitates readily.

The objection to an excess of free lime in the clarified waters is met by the argument, that, in the majority of cases, this quantity is reduced to such an extent on the effluent joining and mixing with the main stream, that it cannot have any injurious effect on fish, &c., and that further a portion, if not all, of this excess of lime is precipitated rapidly by the carbonic acid and sulphates in the river water. Nevertheless the necessary amount of lime to be added and whether other salts such as sulphates should be added too, must be in each separate case determined.—J. W. L.

PATENTS.

An Improved Process for Softening and Purifying Water. R. E. Phillips, London. From F. S. Harwood, Carcavellos, Portugal. Eng. Pat. 2761, February 24, 1888. 8d.

THE lime, earthy, and organic matter held in suspension are precipitated by passing the water over non-oxidisable electrical conductors through which positive electricity is discharged into the water. The hydrogen gas evolved may be collected and utilised as required.—B. T.

An Improved Process for Disinfecting and Purifying Sewage. R. E. Phillips, Carcavellos, Portugal. Eng. Pat. 2762, February 24, 1888. 8d.

A CURRENT of positive electricity is passed through the sewage. The "ozonized oxygen" thus produced oxidises the organic matter and causes it to subside whilst the hydrogen which is liberated at the same time is collected in suitable receivers and utilised for heating or lighting purposes. The arrangement of the apparatus is shown in a drawing.—E. E. B.

XIX.—PAPER, PASTEBOARD, Etc.

PATENTS.

Improvements in Apparatus for Use in Boiling Esparto Grass and other Fibrous Materials. J. Turnbull, junior, Glasgow. Eng. Pat. 4931, April 3, 1888. 6d.

INSTEAD of causing circulation of the alkaline liquors through esparto by means of vomiting pipes as ordinarily, the

inventor attains the same result by means of the pumps A. In this way a partial vacuum is created in the chamber formed by the plates C² and C¹. The liquor is drawn away by the pipes B, and is discharged and spread over the grass by the pipes B². The boilers may be charged in the usual way, or the grass may be filled into cages D, which are then let down into the boiler.—E. J. B.

An Improved Process of Treating Fibre-bearing Plants and Fibrous Materials. S. S. Boyce and P. P. Steele, New York, U.S.A. Eng. Pat. 16,081, November 6, 1888. 6d.

This invention relates to the treatment of flax, hemp, china grass, &c., for the preparation of finer and stronger fibres than by the present methods of retting.

The dried stems are first crushed by passing them between fluted rollers. They are then treated in a bath of hot soft water for about five minutes, and afterwards passed again through rollers to expel the softened or partially dissolved glutinous matters.

The next step is to boil the material for about five minutes in an emulsion made by mixing alkali with any fixed animal, vegetable, or mineral oil—preferably the

natural oil derived from plants similar to those undergoing treatment. The material is then washed and dried. The last process consists in passing it through rollers for the purpose of removing extraneous matters, and separating the fibres.—E. J. B.

Improvements in Printing Designs upon Pyroxyline Compounds to be used for the Production of Collars, Cuffs, Shirt Fronts, Cards, and other Articles. O. Imray, London. From J. R. France, New York, U.S.A. Eng. Pat. 17,691, December 4, 1888. 4d.

For the purpose of producing indelible designs, sheets of celluloid in the "green" or "unseasoned" condition are printed in an ordinary printing-press, with any desired pattern, an ink being employed "in which chemicals or alcohols having an affinity for celluloid are mixed with a dye such as will mix with these chemicals and with the solvents contained in the celluloid." After being allowed to season for several days the sheets are pressed between "steam tables," at a temperature of 150° to 200° F., and at a pressure of from 1,500 to 2,000 lbs. to the square inch. The heat and pressure serve to incorporate the solid matter of the ink into the body of the sheet, and render the surface plastic and even.—W. E. K.

Improvements in the Manufacture of Celluloid and similar Compounds, and Apparatus therefor. O. Imray, London. From J. R. France, New York, U.S.A. Eng. Pat. 17,692, December 4, 1888. 8d.

The object of this invention is to enable the manufacturer to dry nitrocellulose expeditiously and safely. For this purpose the wet material is packed in the chamber of the press. The ram 6 is then raised by hydraulic pressure and maintained at a pressure of 400 lb. per sq. in. for one hour. The water thus expressed is removed by the perforations 16 at the bottom, and through the head 25 and pipe 34. The air cock 34 is then opened and compressed air allowed to enter from the receiver 32. By this treatment a further quantity of moisture is removed. The cock 34 is then closed and 95 per cent. alcohol is allowed to flow in through the pipe 31. In this way the remainder of the water is driven out into the vessel 41, placed on the weighing machine, which is so arranged that as soon as the weight 39, which is equal to the amount of water in the pulp, has been counterbalanced the electric bell 40 is caused to ring. When this happens the receiver 41 is changed for one to collect the alcohol, which is driven out of the press by means of compressed air. The nitrocellulose is then ready for treatment with solvents.—E. J. B.

Improvements in and relating to Boilers for Use in Treating Wood or other Fibrous Matters with Acid Solutions.
A. Lundberg, Northfleet, Kent. Eng. Pat. 17,376, December 7, 1888. 8d.

The inventor employs a lining composed of a thin backing sheet d of zinc, iron, copper, or copper alloy, coated with a layer of lead or lead alloy, &c.

The lead must be fused on to the backing so as to secure perfect metallic contact, for this purpose the surface should be previously tinned. The method of applying the coating is shown in Fig. 2, which is drawn half natural size. At 4

Fig. 1.

Fig. 2.

the backing plate is bent over the edge of the boiler-plate, and its lead coating hammered down as at *l*. The construction of the boiler and the way in which the coating is applied are also shown in Fig. 1.—E. J. B.

An Improved Manufacture of Paper and Cardboard.
A. Diana (formerly Lewis) Lesa, Italy. Eng. Pat. 18,658, December 20, 1888. 4d.

This invention relates to the manufacture of sheets of paper having two faces of different colours or qualities. The usual method of preparing such paper is to employ two wire cloths, one placed above the other. The two kinds of paper thus separately made are united together as they pass through the wet press. The present method consists in causing pulp in a liquid condition to flow on to the already formed sheet of paper before it leaves the wire cloth, the most suitable place being between the suction-boxes.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Report of New Discoveries and Applications of Medicinal Chemicals. Merck's Bull. 1, [6].

Camphoric Acid.—(This Journal, 1888, 865.)

The topical applications which showed styptic action on the mucous membranes within two minutes were in some instances as weak as $\frac{1}{2}$ per cent. The special cases for which particular strengths of solutions for topical application were recommended (Rep. of Berlin Med. Soc.) are as follows:—

In *Acute Angina*, *Acute* and *Sub-acute Pharyngo-Laryngitis* and *Trachitis*, *Acute Bronchitis*, and *Cystitis*. It is defined as a mild, non-irritant antiseptic.

Chromic Acid.—Described and recommended as a *Local Anti-diaphoretic*. Used by Official decree in the Royal Prussian War Department, as the best and most harmless preventive of foot-sweat in the case of marching troops. A 10 per cent. solution of the acid is used.

Bismuth Salicylate.—A true basic compound, in order to possess the properties desirable for its specific medical uses, especially the capability of being borne by the stomach without irritation, must be a definite chemical compound, not a mixture of an acid salicylate with bismuthous oxide. Its salicylic acid must therefore be so chemically united to the base that no solution of the acid can be effected by such solvents as ethylic alcohol, ether, or chloroform.

Basic Bismuth Salicylate (Merck), containing 63 per cent. of bismuthous oxide, all combined with salicylic acid, is recommended (E. Ehring) for the various gastro-intestinal complaints of infants. It is recommended, not in the form of powder, but as a mixture, and is described as an *astringent* and an *energetic disinfectant*.

Cerium Oxalate has proved a useful sedative in sickness, hysteria, and an astringent in gastro-intestinal catarrh. It exerts a peculiarly sedative action on the sympathetic nerves. No ill effects were observed from its use, even when doses as large as $1\frac{1}{2}$ grms. were repeated several times a day. Dr. Gardner, of New York, has pronounced it the best specific against sea sickness that has so far been made known.

Ephedrine Hydrochloride occurs in colourless needles, melting at about 210° C., easily soluble in water, less so in alcohol, but insoluble in ether. Its aqueous solution was found by Miura, of Tokyo, to be permanent under the influence of light. The simple alkaloid, discovered by Nagai, which is the base of the above salt, is also obtained in colourless crystals. From other species of *Ephedra* than that yielding *Ephedrine*, Merck has obtained a different alkaloid, termed by him *Pseudo-ephedrine*. Its hydrochloride is very readily soluble in water and in alcohol. From the ether-alcohol solution it crystallises in colourless needles, melting at 174–176° C.

From the evidences afforded by many experiments on the human subject, Miura infers that ephedrine hydrochloride is a convenient *mydriatic*, and a good substitute for homatropine in examinations of the fundus of the eye. The *Kava-resins* (from the root of *Macropiper methysticum*) are characterised by a peculiar sedative and benumbing effect. The root referred to is well known to the Polynesian natives, who produce from it an intoxicating liquor. Contact with the root causes a biting sensation on the tongue, which afterwards leaves that organ almost devoid of sensation for a certain time. Though the organic principle in the root producing the sedative and benumbing effects referred to may be different from that to which the diaphoretic and diuretic effects are due, yet the fact has been established that the various medicinal virtues of the kava-root are pretty fully concentrated in the two peculiar resins first isolated by Lewin, and termed *Alpha-kava-kava resin* and *Beta-kava-kava resin*. These resins present all the specific effects of the crude drug kava as local anæsthetics. Yet the crystalline, odourless and insipid neutral principle

Kavakin or *Methysticin*, isolated from the same root, is reported by Lewin as possessing no physiological action. It occurs as silky white needles, soluble in alcohol and in ether, and melting at 130° C. C. Pomeranz, in 1888, established its chemical individuality as that of a derivative of the methyl ether of catechol (pyrocatechin).—W. S.

Apiol. G. Ciamician and P. Silber. Ber. 22, 119—121.

If apiolic acid be heated with alcoholic potash to 180 in sealed tubes it yields a crystalline product with a smell of phenol, boiling at 298° and melting at 105—106°. It has the formula $C_6H_{10}O_4$. With ferric chloride it gives a dark violet colouration changing to brown. This body has probably the constitution $C_6H_2(OH)_2(OCH_3)_2$. The presence of two methoxyl groups was determined by Zeisel's method. (Compare this Journal, 1888, 399 and 583.)

—J. B. C.

γ- and δ-Isotropic Acid. C. Liebermann. Ber. 22, 124—130.

From a by-product from cocaine the author has isolated two acids, which from their similarity to Fittig's α- and β-isotropic acid, he calls γ- and δ-isotropic acid. The former can be converted into a new acid of the same composition, which is therefore named ε-isotropic acid. The γ-acid on distillation yields cinnamic acid and a small quantity of an oily by-product. The γ-acid also gives cinnamic acid on distillation, though in smaller quantity. On boiling the acids with acetic anhydride and sodium acetate the anhydrides are formed. The anhydride of the γ-acid yields on heating with an alkali the ε-acid. With cone. sulphuric acid, the sulphonic acids of γ- and δ isotropic acid are formed.

—J. B. C.

The Cocaines. C. Liebermann. Ber. 22, 130—133.

By bringing together 2 parts of ecgonine, 1 part of water and 2 parts of γ-isotropic-anhydride and heating on the water-bath, isotropyl-ecgonine is formed, which after drying may be mixed with isotropic acid, dissolved in methyl alcohol and saturated with hydrochloric acid gas. On evaporating off the methyl alcohol and the acid, dissolving in water and shaking out with ether, the ethereal solution leaves on evaporation isotropyl-cocaine of the formula $C_{19}H_{23}NO_4$. This substance is identical with the natural product.

By the same process the author has prepared anisyl-ecgonine and anisyl-cocaine.—J. B. C.

Occurrence of Cinnamic Acid among the Decomposition Products of Crude Cocaine. H. Franfeld. Ber. 22, 133—134.

THE crude cocaine is exhausted with boiling water, which takes up the greater part of the free acid. From the residue a cold dilute solution of alkalis dissolves γ- and δ-isotropic acid. The residual ethereal salts are decomposed by a boiling solution of caustic alkali and the γ- and δ-isotropic acids dissolve. The first aqueous extract contains cinnamic acid which may be isolated by means of its calcium salt.—J. B. C.

Morphine. L. Knorr. Ber. 22, 181—185.

METHYLMORPHINE-METHYL IODIDE is decomposed on boiling with silver oxide into methylmorphimethine—

This latter body decomposes into an amine and non-nitrogenous substance, which appears to be an anthracene derivative.

The methyl iodide of methylmorphine is treated in aqueous solution with silver oxide, which removes the iodine, and the hydroxide is evaporated in a distilling flask connected with a receiver containing hydrochloric acid. The contents of the flask gave up to ether a crystalline substance of the formula $C_{15}H_{10}O_2$. The receiver contained the

hydrochloride of trimethylamine. Methylmorphimethine, when heated with acetic anhydride to 160—200°, yields four different bodies, viz., acetylmethylidoxypheanthrene, an oil with basic properties, an oily ethereal salt, and a volatile base which was identified as dimethylamine.—J. B. C.

The Alkaloids in Cocaine. A. Einhorn. Ber. 22, 399—402.

THESE investigations were limited to the by-products in the preparation of ecgonine hydrochloride from cocaine. The cocaine is decomposed with concentrated hydrochloric acid into ecgonine, which is precipitated by the addition of alcohol and ether. The filtrate on evaporation leaves a syrupy liquid. The syrup is dissolved in water, filtered, and caustic soda added, which precipitates a light coloured compound. This precipitate when dry partly dissolves in alcohol, from which a crystalline substance is obtained. The new product has probably the formula $C_{20}H_{25}N_2ClO$. The filtrate from this compound, after acidifying with hydrochloric acid, yields on evaporation crystallised anhydro-ecgonine. This substance is decomposed by hydrochloric acid at 270° into hydrocarbons, methyl chloride, ammonia, methylamine, and also basic substances, one of which yields a nitroso compound and the other is unchanged by the action of nitrous acid, but forms a double chloride with chloride of gold. Both bases when distilled with zinc dust yield oils smelling of pyridine.—J. B. C.

The Salicylates of Cresol. H. Nencki. Compt. Rend. 108, 254—255.

THESE bodies are prepared by the same method as salol. Three well crystallised salts may be obtained insoluble in water, and with difficulty soluble in alcohol, viz., the derivatives of ortho-, meta-, and para-cresols melting respectively at 35°, 74°, and 39°. Their odour is not quite so strong as that of salol. The ether of o-cresol has a slightly burning taste, the para-compound is absolutely tasteless. Not only by the pancreatic juice, but also by the muscles, these substances are decomposed into their constituents, and their antiseptic action is identical with that of ordinary salol. The p-cresol produced thus by the decomposition of the corresponding salicylate, is partly eliminated from the body, combined with sulphuric acid, and partly oxidised to benzoic acid.—A. R.

Phenylpropionic Acid and Phenylacetic Acid. C. T. Williams. Pharm. Journ. and Trans. 1889, 701.

Phenylpropionic Acid, $C_9H_{10}O_2$, is described as occurring in acicular crystals of reddish-white colour, insoluble in water but soluble in spirit (1 : 6), and having a feebly acid reaction. The solution has a not unpleasant sour aromatic taste and a pleasant aroma. The alcohol solution was administered in 10 minim doses diluted with an ounce of water, which were generally increased to 20 minims in two ounces of water, three times a day. As a rule the medicine caused neither nausea, vomiting nor anorexia, except in two cases in which the nausea was overcome by further dilution of the medicine with water. As a result of the treatment, 13 cases improved, four remained stationary, and three became worse, and it was inferred that phenylpropionic acid exercises more influence on suppuration than on tuberculation. In the improved cases, there was decided increase of appetite and gain of weight, colour, and vigour.

Phenylacetic acid tastes like the foregoing, but has a more acid reaction. It dissolves in alcohol (1 : 6), and in this condition is taken up by a small quantity of water. The alcoholic solution was given in doses of 10 to 20 minims three times a day, to 19 cases of phthisis, for periods ranging from 21 to 29 days, and in no case gave rise to unpleasant symptoms. Thirteen of the cases improved greatly, four deteriorated, and three remained stationary, the improvement consisting in gain in weight, strength, and colour, partly due to diminution of cough and expectoration. From the general results of the experiments with the two compounds, it is concluded that phenylpropionic and phenylacetic acids given in phthisis promote appetite,

digestion, and assimilation, and are well tolerated in considerable doses; also that the use of phenylacetic acid is more indicated in cases of tuberculation and that of phenylpropionic acid in excavation cases.—W. S.

PATENT.

Improvements in Apparatus for the obtainment of Oxygen and Nitrogen Gases from Atmospheric Air. E. B. Ellice-Clark and L. Chapman, London. Eng. Pat. 3880, March 13, 1888. 1s. 1d.

THESE improvements relate to apparatus used in Brin's process, Eng. Pat. 157 of 1885. (This Journal, 1885, 568, and 1886, 34.) They comprise 11 claims bearing upon the shape, arrangement, luting and connexion of the retorts, the heating chamber or furnace, the water chamber, supports for the baryta, and other details of construction, for particulars of which the specification and sheets of drawings must be consulted.—B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

A Method for producing Photographic Emulsions not requiring a Base or Support as Photographic Films. E. S. Williams, Dublin. Eng. Pat. 4874, March 31, 1888. 6d.

THE sensitive emulsion itself forms the film and does not require to be placed upon any temporary or permanent support. The melted emulsion, containing a somewhat large proportion of gelatin, is thoroughly mixed with some chromium compound, preferably ammonium or potassium dichromate, and spread in the usual manner upon a levelled glass plate or some other suitable smooth support. When the emulsion has set, the support with the emulsion upon it is immersed in a solution of sulphurous acid or its salts until the dichromate is completely reduced. It is then thoroughly washed with water, dried, and the emulsion stripped from the support and cut up. The dried emulsion forms a perfectly insoluble film, which may be exposed from either side, and the resulting negative may be printed from either side without loss of sharpness.—C. H. B.

XXIII.—ANALYTICAL CHEMISTRY.

The Meldometer. J. Joly. Industries, 1889, 20.

THE meldometer is designed for the purpose of ascertaining the melting and boiling points of small quantities of substances. It consists essentially of two pairs of forceps mounted on a stage and carrying between them a thin platinum ribbon. Through this ribbon an electric current may be passed, the strength of the current being regulated by a carbon-mercury rheostat. The apparatus is mounted on the stage of a compound microscope, provided with a one-inch objective. The substance to be examined is placed in focus on the platinum ribbon, and then the current is gradually increased until the substance is melted or volatilised. Experiments made in this way show interesting phenomena, sufficiently characteristic in many cases to identify a substance at once. By arranging side by side different fragments it is easy to find their order of melting points with greater exactness than can be the case when the blow-pipe is employed.

The meldometer is also of value in studying sublimates. A piece of glass is held over the heated strip, and upon this the sublimate deposits. A long series of trials have led to the conclusion that the appearances so obtained are excellent as tests to the mineralogist and chemist.

—W. W. H. G.

Detection of Nitrates in Soils. Kreusler. Landw. Jahrbuch, 1888.

B. FRANK observed that certain quartz granules gave a blue colouration with diphenylamine even after repeated washing with water. This he attributed to a special surface attraction which enabled the granules to retain nitrates. The author of the present note points out that the blue colouration is produced in all cases where manganic or ferric oxides are present in a soil or sand, and suggests that Frank was most likely dealing with these oxides and not with nitrates.

—D. A. L.

Test for Glass by Colour Reactions. F. Mylius. Ber. 22, 310—314.

THE presence of free alkali in glass may be determined by the blue iodide of starch reaction. As the blue colour is produced only in the presence of an iodide, starch solution, mixed with an aqueous solution of iodine and a few drops of silver salt, to precipitate any free iodide, is added to the glass. The presence of alkali, by forming a soluble iodide, is indicated by an immediate blue colouration. The intensity decreases with different kinds of glass, in the following order:—

Lead glass.
Thuringian glass.
Thermometer glass.
Bohemian glass.

Another method is to place the glass in moist ether. The glass absorbs water, which, in its turn, dissolves alkali. If the ether be now replaced by an ethereal solution of free eosin or eosin iodide (not the alkaline salt), the dissolved alkali frees the colouring matter on the surface of the glass, and the intensity of the colour depends on the quantity of free alkali.—J. B. C.

Action of Chlorine on Carbon Dioxide. R. Lucien. Chem. Zeit. 13, 32.

EXPERIMENTS conducted in a variety of ways showed that chlorine has no action on dry carbon dioxide. In the presence of moisture chlorine disappears from the mixture of gases when passed through a red-hot tube, not in the form of carbonyl chloride, but as hydrochloric acid. Although it would seem as though the carbon dioxide did not take any part in the reaction, it was found that on passing a mixture of damp air and chlorine through a red-hot tube less chlorine united with the hydrogen of the water than when the mixture consisted of damp carbon dioxide and chlorine, the relative volumes remaining the same.—J. W. L.

Analytical Notes. C. La Harpe and F. Reverdin. Bull. Soc. Chim. 51, 163—165.

Detection of Carbon Monoxide in the Air.—The presence of carbon monoxide in the air can be detected as follows:—A moderately slow stream of the air to be tested, previously filtered through cotton or glass-wool, is passed to the bottom of a fractionation flask containing pure dry iodic acid and placed in an oil-bath heated to 150°C; the side tube is bent downwards into a vessel containing a solution of starch in distilled water. The carbon monoxide is thus oxidised to carbon dioxide, iodine is liberated, and the starch solution coloured blue. It was proved by experiment that an appreciable colouration is produced when 9 litres of air containing only 1 to 2 parts of carbon monoxide in 100,000 were passed in the course of about 20

minutes; it is probable that this gas could be detected when present in even smaller quantities provided a larger volume of air was employed. Any other reducing substances present in the air to be tested must of course be previously removed in the usual manner.

Modifications of Bausen's Apparatus for estimating Manganese and Chromates.—In estimating manganese or chromates by Bausen's method the bulb (a) often becomes filled with air or inert gas at the commencement of the operation. The liquid is thus driven back into the bulb (b), and there becomes heated. In order to obviate any such action and to prevent the liquid in the flask (c) from being carried over into the bulb-tube, the author employed the following apparatus:—

The tube *d* is provided with a small bulb, very loosely plugged with glass-wool and passes through a small condenser into the bulb tube *a*, which is provided with three hemispherical bulbs 1, 2, 3. At the commencement of the operation the inert gas, containing only small quantities of chlorine, is passed into *b* just above the bulb 1, so that it circulates from one bulb to the other and passes out free from chlorine. As soon as the gas evolved is completely absorbed the tube is pushed to the bottom of *b* and the operation concluded as usual.

In analysing chromates it is advantageous to add a little manganese dichloride as well as hydrochloric acid, as reduction then takes place much more quickly.—F. S. K.

Separation of Zinc from Nickel. II. Baubigny. *Compt. Rend.* 108, 236—238.

WHEN dilute solutions of zinc sulphate are treated with H_2S , all zinc is precipitated even in presence of six times the quantity of free acid contained in the sulphate. Thus 0.06 gm. of $ZnSO_4$ dissolved in 200 cc. of water containing 0.27 gm. of SO_3 is nearly completely precipitated as sulphide in eight hours, only 0.0015 gm. of $ZnSO_4$ remaining in solution. Likewise the presence of considerable quantities of acetic acid does not prevent the precipitation of zinc from solutions of zinc sulphate. This may serve as a means of separating zinc from nickel. Thus 0.3 gm. of the mixed sulphates is dissolved in 100 cc. of water containing about 10 per cent. of glacial acetic acid and treated at ordinary temperatures with H_2S . After standing a few hours, the ZnS is filtered off, and to the filtrate sodium acetate is added, and NiS precipitated by passing H_2S into the solution heated to 70° — 75° . Nickel sulphide should always be washed with water containing 1—2 per cent. of acetic acid, otherwise the wash-water runs off turbid. The sulphides are converted into sulphates, and dried at 400° . The numbers found in these experiments agree very closely with the quantities taken. When the mixture contains less than one-third nickel salt, it is superfluous to add acetic acid, since the free acid formed from the sulphate of zinc by the sulphuretted hydrogen suffices to keep the nickel sulphide in solution.—A. R.

On Cobalt and Nickel. G. Krüss and F. W. Schmidt. *Ber.* 22, 11—15.

IN determining the atomic weights of cobalt and nickel, the authors find that if the method of weighing the equivalent of precipitated gold by bringing the respective metals into a neutral solution of gold chloride or the sodium double salt be employed, small quantities of nickel and cobalt are left with the gold. The gold may be freed from nickel and cobalt by redissolving in aqua regia and precipitating with sulphurous acid. On washing the precipitate free from cobalt, the pink colour due to the cobalt gradually pales and then takes a greenish shade. This green solution on evaporation leaves a residue, which dissolves in hydrochloric acid with a green colour. The same kind of residue is obtained in the case of nickel. Larger quantities may be prepared by washing precipitated nickel sulphide with ammonium sulphide until the ammonium sulphide is no longer coloured brown. The oxide of the new substance may be also obtained by fusing cobalt and nickel oxides with an alkali, in which the former dissolves. The new element has the following properties:—The acid solution of the chloride is not precipitated by sulphuretted hydrogen, but by ammonium sulphide in a neutral solution, and forms a black powder. It yields with ammonia a white flocculent precipitate insoluble in excess of the precipitant. Caustic potash produces a similar white precipitate insoluble in excess. The oxide does not yield Thénard's blue, and is soluble in hydrochloric acid after strong ignition. It forms a colourless anhydrous chloride, which in solution changes to green. The metal obtained by reducing the chloride in a current of hydrogen or by electrolysis of the chloride is black.—J. B. C.

A New Acid of Tin. W. Spring. *Bull. Soc. Chim.* 51, 180—182.

A NEW acid is formed when a saturated aqueous solution of stannous chloride, containing sufficient hydrochloric acid to prevent decomposition, is treated with excess of pure barium dioxide at the ordinary temperature. The turbid liquid which is obtained contains a compound of tin in the colloidal condition and does not become clear, either on filtering or standing. The barium chloride in solution is completely removed by dialysis and, on evaporating the solution, a white solid substance is obtained. This compound, when dried at 100° , has the composition $2 SnO_3 \cdot H_2O$. The oxygen and the water were both estimated directly.—F. S. K.

Detection of Mineral Phosphates in Bone-Meal. N. v. Lorenz. *Oesterr.-Ungar. Zeits. f. Rubenzuck. Ind.* 1888, 270—272.

BONE-MEAL is first moistened with 1 : 1 sulphuric acid, but dissolved bones is treated direct with concentrated sulphuric acid. The evolution of hydrofluoric acid indicates the presence of mineral phosphates, as the latter generally contain calcium fluoride. It is stated that the addition of 10—20 per cent. of phosphoric acid to bone-meal can be detected by this means. The calcium fluoride in the bones takes no part in the reaction, and is found by the author to be present in much smaller quantities than is generally supposed.—D. A. L.

New Reaction of Acetanilide. M. Denigès. *Arch. Pharm.* 1888, 529.

MINUTE quantities of acetanilide boiled with a small quantity of sodium hypobromite in alcoholic solution cause the formation of a yellow-red precipitate, while at the same time the smell of methyl-cyanide becomes perceptible. All anilides which form salts and free aniline when boiled with an excess of free alkali react in this way, the free aniline reacting with the hypobromite with formation of the red precipitate.—J. W. L.

On the Estimation by Weight of Glycerol by oxidising it with Potassium permanganate in Acid Solution. H. Grünwald. Zeits. f. angew.Chem. 1889, 34.

PLANCHON'S method for the estimation of glycerol was found by the author to yield very good results. The glycerol is oxidised by potassium permanganate in the presence of sulphuric acid to carbonic acid according to the equation $C_3H_5O_3 + 7 O = 3 CO_2 + 4 H_2O$. The absorption of carbonic acid took place, however, in caustic potash instead of soda lime, as Planchon recommends. The steam was retained by a calcium chloride tower, with which was connected a calcium chloride tube. The acid mixture was heated in a round flask on a wire gauze, and the experiment does not require more than one hour. A number of analyses is given which speak for the excellence of this method.—A. L.

On the Estimation of Resins. Zeits. f. angew. Chem. 1889, 35.

THE most complete examination of resins has been made by M. v. Schmidt and F. Erban. They took three factors into consideration. (1.) How many milligrammes of caustic potash 1 grm. of resin requires for saturation. (2.) How many milligrammes of caustic potash is fixed by boiling 1 grm. of resin with an excess of alcoholic caustic potash (Köttstorfer's number). (3.) How many per cent. of iodine resin is able to fix (Hubl's iodine number).

Experiment No. 1 is made in the following manner:—1 grm. of the finely crushed resin is boiled under reversed condenser with alcohol of 95 per cent., filtered if necessary and phenolphthalein added to the solution. It is then titrated with caustic soda. To obtain Köttstorfer's number, 1 grm. of resin is boiled with 25 cc. of alcoholic caustic potash for 5 to 15 minutes under reversed condenser; then 100 cc. of alcohol are added, and the excess of alkali is titrated, after once more boiling, with hydrochloric acid and phenolphthalein. The third number is obtained by dissolving 1 grm. of resin in hot alcohol, and adding, after cooling, 25 cc. of iodine solution. If the solution be soon discoloured, a fresh portion of iodine solution is added until the mixture remains reddish-brown after prolonged standing. After 24 hours the excess of iodine is ascertained by back titration. The following table contains the three numbers of some of the most important resins used for technical purposes:—

Resins.	No. 1. Acid Number.	No. 2. Kött- storfer's Number.	No. 3. Hubl's Number.	
			With Residue.	Without Residue.
Colophony.....	146.5	168.2	..	116.8
Sandarac.....	141.4	174.4	..	66.8
Benzoin.....	136.3	164.7	..	57.4
Storax.....	130.6	205.6	64.7	58.6
Copal of Angola, white, melted	93.6	118.8	44.9	41.6

Copal of Zanzibar, melted...	..	36.8	12.6	7.6
Asphaltum.....	..	8.1	22.2	3.5

When the resins were dissolved in alcohol or turpentine, the solvent was distilled off with steam. The remaining resins, however, show nearly always a lower acid figure and a lower Köttstorfer's number, part of the acid having been removed by the steam, as the following table shows:—

Resin.	Acid Number.	Köttstorfer's Number.	Iodine Number.		Solvent.
			With Residue.	Without Residue.	
Sandarac.....	139.7	167.8	..	90.1	Alcohol.
House Colophonium.....	130.4	146.8	..	109.6	Turpentine.
Copal of Angola, white, melted.....	81.8	106.1	58.2	56.9	Turpentine.
Venetian Turpentine.....	81.0	110.3	..	103.6	..
Mastic.....	53.5	76.5	81.0	62.4	Turpentine.
Shellac.....	35.7	209.1	8.5	7.9	Alcohol.
Copal of Angola, red, melted.....	32.0	72.3	54.4	47.0	Turpentine.
Elemi.....	29.6	43.3	..	40.9	Alcohol.
Dammar.....	27.7	40.5	66.1	57.4	Turpentine.
Copal of Zanzibar, melted.....	20.3	65.6	52.8	51.3	Turpentine.
Amber, melted.....	..	37.9	20.7	16.4	Turpentine.
Asphalt.....	..	52.1	28.7	16.3	Turpentine.

R. Williams, who has probably no knowledge of this research, estimated the whole quantity of the required caustic potash by boiling for half an hour with half normal alcoholic potash and by titrating the excess with half normal hydrochloric acid and phenolphthalein. For esti-

imating the acid the resin was boiled with strong alcohol and titrated with half normal caustic potash. Hubl's iodine number was found in the usual way. The loss of weight in drying was estimated by heating to 100° C.

To test for resin, a small quantity of it is dissolved in acetic anhydride, and to the cold solution one drop of sulphuric acid is very carefully added. The solution is coloured dark red to blue violet. The colourations disappear however, and the solution appears finally brownish-yellow and fluorescent.—A. L.

On the Determination of Organic Nitrogen by Kjeldahl's Method. C. Violette. *Compt. Rend.* **108**, 181—183.

THE author has determined the nitrogen of the product which remains after the fermentation of maize, and which is characterised by the difficulty of its combustion according to the methods of Dumas, Varentrapp, Will, and Kjeldahl; the results agree closely. The latter method was slightly

modified by the author, Nordhausen acid being employed instead of ordinary sulphuric acid, 25 cc. for 2 grms. of the substance under examination. Mercury, while favouring the reaction, renders the results very inexact, part of the nitrogen being retained.—A. R.

On Nitrogen Determinations by Kjeldahl's Method. E. Aubin and Alla. *Compt. Rend.* **108**, 246—248.

A comparison is drawn between Varentrapp-Will's and Kjeldahl's method, and the latter is found to be the better of the two. In the former the greatest importance attaches to the proportions in which the substance to be analysed is mixed with soda-lime, as well as the temperature employed. Thus with 1 gm. of linseed cake and a bright red heat, 7.53 per cent. of N were obtained; with 2 grms. and the same quantity of soda-lime: at a dull red heat 6.89 per cent.; at a bright red heat 4.62 per cent. The author therefore always employs 25—30 grms. of soda-lime for every 0.5 gm. of organic substance.

The best proportions in Kjeldahl's method are: 0.5 gm. of organic substance, 20 cc. H_2SO_4 of 66° B., and 0.5 gm. of mercury. The time occupied for complete decomposition is at most $1\frac{1}{2}$ hours, and the liquids obtained are perfectly colourless and limpid. By adding phosphoric acid the time of transformation is much abridged. There is no loss of ammonia whatever. For estimating nitrogen in soils the method is invaluable. As large a quantity as 1,000 grms. were employed for one determination.

A table is appended which shows that this method always gives slightly higher results than Varentrapp-Will's. An advantage of the former is the fact that the substance under examination need not be powdered, and if not homogeneous a large sample may be made into a paste with sulphuric acid and an aliquot part taken for the determination.—A. R.

Estimation of Fat in Butter-Milk by Soxhlet's Areometric Method. J. Sebelien. *Landw. Versuchs-Stat.* **35**, 335—337.

THE fat was determined in 19 samples of butter-milk from sour cream and in 12 samples from sweet cream, by the author's gravimetric method and by Soxhlet's areometric method. With the sour milk the Soxhlet method was in one case 0.3 per cent. too low; in three cases the error was greater than 0.1 per cent., and in the remaining 15 less than 0.1 per cent. of fat. With the sweet milk two results were respectively 0.2 and 0.13 per cent. too high, whilst in the remaining 10 samples the error was less than 0.1 per cent.—D. A. L.

The Detection of Fusel Oil in Alcohol. L. v. Udranszky. *Zeits. f. Phys. Chem.* **12**, 355.

THE author recommends the furfural reaction. He has examined the behaviour of numerous substances with a mixture of furfural, water, and sulphuric acid, and has found that many bodies give characteristic reactions with this mixture. α -naphthol is particularly sensitive, and by its means 0.0000026 gm. of furfural may be detected with certainty. On the other hand, certain impurities of spirit give a colour reaction with furfural and sulphuric acid. These bodies are removed by filtration over animal charcoal. The presence of these bodies as well as furfural, in spirits is, according to the author, the cause of the browning produced on heating with strong sulphuric acid. The author considers the reaction with furfural indicative of the presence of fusel oil in most cases. Other bodies, however, give the reaction, especially such as are extracted from the cask during storage.—H. T. P.

A Simple Method for the Detection of and Estimation of Impurities in Commercial Spirit. M. L. Godefroy.

THE method only varies from the usual one of adding strong sulphuric acid, in the addition of a little benzene, which strengthens the colourations. Windisch (*Zeits. f. Spiritusind.* **11**, 145) condemns this method altogether. For quantitative purposes it is quite useless, and for qualitative

purposes it possesses no advantages over other methods, but, on the other hand, may lead to errors. Windisch draws attention to the researches of F. L. Eckmann, as regards the fusel oil contained in corn brandy, and its detection. The author has shown that fusel oil contains of the higher alcohols, between ethyl and amyl alcohols, only normal propyl and isobutyl alcohols. The composition of fusel oil is—

Per Cent.

3—12 of propyl alcohol.

15—47 of butyl „

44—71 of amyl „

5—7 of remainder, volatile with difficulty.

—H. T. P.

PATENTS.

Improvements in and Apparatus for determining Temperatures and Barometric Pressures. J. G. Wiborgh, Stockholm, Sweden. Eng. Pat. 2673, February 22, 1888. 11d.

See this Journal, 1889, 214—215.

Improvements in Means or Apparatus for ascertaining the Specific Gravity of Liquids. J. J. Hicks, London. Eng. Pat. 4139, March 17, 1888. 8d.

The specific gravity of liquids is ascertained by dipping into them a glass tube open at top and bottom, and containing a number of loosely superposed glass bubbles carefully calibrated to different specific gravities, the heavier ones below, the lighter above. Upon the tube being inserted into the liquid, those bubbles which are of less specific gravity than the liquid will float, and thus indicate that of the liquid with an accuracy sufficient for many purposes.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Figures 1 and 2 show one modification, the glass tube being flattened in cross section, with bubbles to correspond. The instrument is provided with a hook at the side for suspension, and has sundry holes in its length for facilitating the entry and exit of the liquid. The bubbles may be marked with figures, or be made in different colours or shapes to indicate different gravities. The tube may also be used as a "pipette," in which case the upper opening is reduced in size and the intermediate holes are omitted. Another arrangement is shown in Figures 3 and 4, where the bubbles are held within a space formed by three upright glass rods instead of within a tube.—B.

Improvements in Clinical and other Thermometers. J. J. Hicks, London, and T. P. Salt, Birmingham. Eng. Pat. 4212, March 19, 1888. 8d.

CHEMICAL and other thermometers, under this patent, are made with a layer of ruby or other coloured glass behind the bore, backed by a layer of opaque enamel, through which means the contents of the bore as well as the divisions on the glass are more readily made visible and the instrument becomes more ornamental.—B.

New Books.

TECHNISCH-CHEMISCHES JAHRBUCH, 1887—1888. Ein Bericht über die Fortschritte auf dem Gebiete der Chemischen Technologie, vom April 1887 bis April 1888. Herausgegeben von Dr. RUDOLF BIEDERMANN. Zehnter Jahrgang. Mit 328 in den Text gedruckten Illustrationen. 1889. Berlin: Carl Heymanns Verlag. London: H. Grevel & Co., 33, Covent Garden.

OCTAVO volume bound in cloth and containing Table of Contents, List of Journals quoted from with abbreviated names, 558 pages of Subject-Matter copiously illustrated with 328 engravings, and a List of New Books on Physics, Chemistry, Chemical Technology, Mineralogy, Geology, and Botany; also Miscellaneous Subjects during the year. A full index of authors and of subject-matter closes the work.

The subjects treated of are as follows:—I. Iron and Steel. II. The Alkali Metals, Magnesium, and Aluminium. III. Gold and Silver. IV. Copper. V. Lead. VI. Zinc. VII. Tin. VIII. Nickel and Cobalt. IX. Manganese and Chromium. X. Antimony, Arsenic, &c. XI. Chlorine and Hydrochloric Acid. XII. Sulphur and Sulphuric Acid. XIII. Oxygen, Hydrogen, Carbonic Acid, &c. XIV. Soda. XV. Potassium Compounds. XVI. Ammonia. XVII. Alkaline Earths. XVIII. Alumina. XIX. Glass. XX. Earthenware and its Production. XXI. Cements. XXII. Artificial Stone. XXIII. Explosives. XXIV. Illuminating Agents. XXV. Fuels and Furnaces. XXVI. Sugar, Materials and Production. XXVII. Starches and Starch Sugar. XXVIII. Wine. XXIX. Beer. XXX. Spirits. XXXI. Fats, Resins, and Soaps. XXXII. Water. XXXIII. Foods. XXXIV. Manures. XXXV. Tanning and Leather. XXXVI. Organic Acids. XXXVII. Alkaloids. XXXVIII. Colouring Matters and Dyes. XXXIX. Textile Fibres, Bleaching, Dyeing, and Calico Printing. XL. Paper. XLI. Photography. XLII. Apparatus. XLIII. New Books.

CHEMISCH TECHNISCHES REPERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der technischen und Industriellen Chemie mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 1888. Erstes Halbjahr. Zweite Hälfte. Berlin: R. Gaertner's Verlagsbuchhandlung, Hermann Heyfelder. London: H. Grevel & Co., 33, Covent Garden.

OCTAVO volume in paper cover; the second issue for the first half-year of 1888. It contains 178 pages of subject-matter plentifully illustrated with wood engravings, and in these the following subjects are treated:—Food Stuffs; Paper; Photography; Manures, Refruses, &c.; Soaps; Explosives and Matches; Preparation and Purification of Chemicals; Chemical Analysis; Apparatus, Machinery, &c. Appendix. New Books.

Together with the foregoing is issued the GENERAL INDEX of the CHEMISCH TECHNISCHES REPERTORIUM from 1882 to 1886.

THE LIXIVIATION OF SILVER ORES WITH HYPOSULPHITE SOLUTIONS WITH SPECIAL REFERENCE TO THE RUSSELL PROCESS. By CARL A. STETEFELDT. The Scientific Publishing Company. New York: 27, Park Place.

IN this volume is described the Lixiviation process of treating ores. The work commences with the preface and table of contents, after which follow 223 pages of subject-matter, two plates containing plans of the Lixiviation plant and apparatus, and a carefully arranged alphabetical index. The text is embellished with 30 engravings and is sub-divided as follows:—Introduction. PART I. The Chemistry of the Lixiviation Process. Chap. I. The Chemicals. II. The Chemical Reactions. The Reactions of Sodium Hypo-sulphite solutions. Solubilities of Metals and Various Compounds in Sodium Hypo-sulphite Solutions. III. The Reactions of Extra-solutions. (i) Reactions of Extra-solutions with Caustic Soda and Sodium Carbonate. (ii) Decomposition of Extra-solution by heating. (iii) Decomposition at Ordinary Temperature. Solubilities of Silver, Gold, Lead, Silver Sulphide, and Gold Sulphide in Extra-Solution. The Effect of Extra-solution on Silver Ores and on Ores that have been subjected to a chloridising-roasting. IV. The Extraction of Gold. V. The Chemistry of the Wash Water. VI. The Chemistry of Sodium and Calcium Sulphide. VII. Laboratory Work. Lixiviation Tests with Extra-Solution. PART II. THE LIXIVIATION PROCESS IN ITS PRACTICAL EXERCISE.—Chap. XI. The Lixiviation Plant. XII. The Solutions. XIII. The Charging and Discharging of the Lixiviation Vats. The Second Wash Water. General Rules for Handling the Lixiviation Solutions. XIV. The Treatment of Roasted and Raw Ores.

Treatment of the Silver-bearing Wash Water. The Lixivation. XV. Through-Lixivation. XVI. The Precipitation of the Metals from a Lixivating Solution. XVII. The Construction, Cost of Erecting, and Expense of Running a Lixivating Mill. A. Notes on Construction. B. Estimated Cost of Mill Plant. C. Estimated Cost of Running a Lixivation Mill of 80 Tons Capacity per Day. XVIII. The Russell Process compared with Ordinary Lixivation and with Amalgamation.

The volume is strongly bound in cloth and is furnished with a supplement inserted in the book. It contains also a table of Errata.

HANDBOOK OF PATENT LAW OF ALL COUNTRIES. By W. PHILLIPS THOMPSON, C.E., F.C.S., Member of the Institute of Mechanical Engineers, &c., &c. Eighth Edition, Revised, 1888. London: Stevens and Sons, 119, Chancery Lane. New York: D. van Nostrand, 23, Murray Street.

SMALL 8vo, volume, bound in cloth, with table of contents, preface, and 154 pages of subject-matter.

With regard to British Patents, the following subjects are clearly and concisely treated of: Varieties of Protection; What can be Patented; Who can Patent; General Rules relating to Patents; First Step in Patenting; Procedure and Cost of obtaining Patent; Subsequent Taxes; Prolongations; Amendments; Revocation of Patents; Infringement of Patents; Legal Proceedings; Licenses and Assignments. The next class of subjects similarly dealt with is comprised under "General Hints." What Inventions are Profitable; How to Sell a Patent; Caution to Investors in Patents; How to Safely Invest in Patents; Searching. Then follows the important subject of the Registration of Designs, and finally, a concise and well-subdivided treatise on the Foreign Patent Laws.

BOOK OF CHEMICAL LABORATORY LABELS. Compiled by W. H. SYMONS, F.R.M.S., F.C.S., F.I.C. Henry Kimpton, 82, High Holborn, London, W.C.

THE labels in this book are printed with bold type in accordance with modern Chemical nomenclature. The size is such that the whole label may be seen from the front of most bottles. The name of the substance only is given, so that the same label may be used for crystal, powder, or solution. The type being uniform in character, the halves of two labels may be combined to furnish a label for an uncommon compound. As an experiment, labels for some of the most corrosive chemicals have been printed on parchment as well as on paper. The formulae and formula weights are given separately, and can be added to the label when they are required in this position. There are also a number of additional slips for use in special cases.

The set is published in three parts:—

PART I. contains 160 labels for common reagents, and 130 additional slips, together with sheets of formulae and formula weights. It is intended to supply the wants of the average student.

PART II. comprises about 400 labels, it includes special reagents and other substances required by the practising chemist.

PART III. contains 160 large labels suitable for stock bottles, volumetric solutions, &c.

Price for each Part, 1s.; for the set of three Parts, 2s. 6d.

A TREATISE ON MANURES, OR, THE PHILOSOPHY OF MANURING. A Practical Handbook for the Agriculturist, Manufacturer, and Student. By A. B. GRIFFITHS, Ph.D., F.R.S.E., &c., Lecturer on Chemistry in the School of Science and in the Grammar School, Lincoln, &c. London: Whittaker and Co., 2, White Hart Street, Paternoster Square, London, E.C. George Bell and Sons, York Street, Covent Garden. 1889.

THIS book forms one of the Specialists' Series issued by the above firm of publishers. It is an 8vo. volume, bound in cloth, and containing frontispiece, preface, table of contents, and including the introduction, 389 pages of subject-matter. An alphabetical index closes the work. The text is illustrated with 15 wood engravings, including the frontispiece. The following will serve to show the manner in which the subject is generally treated:—Chapter I. is principally devoted to Historic Treatment and the Rise and Development of Scientific Agriculture. II. Constituents of Plants, Root-absorption, Assimilation, &c. III. Soils and Manuring. IV. Sheep-fold, Blood, and other Animal Manures; Refuse as Manures. V. Artificial Manures. VI. Guano. VII. Coprolites and Mineral Phosphates and Fertilisers. VIII. The Manure Works and Processes. IX. Artificial Nitrogenous Manures. Their Valuation. X. Potash Manures, &c.; Gas Lime, Manganese Salts, &c. XI. Iron Sulphate as a Manure, and as a Precipitant and Disinfectant for Sewage. XII. Ville's System. XIII. Mixed or Special Manures. XIV. The Application of Manures, &c. XV. The Valuation of Manures. XVI. Analysis and Sampling of Manures. Kjeldahl's Method for Nitrogen. XVII. Conclusion. Comparative Value of Farmyard Manure, &c. "Artificiality." Agricultural Colleges.

APPENDIX.—Rotation of Crops. Useful Data concerning the Growth of Crops, about Pasture Grasses, Clovers, and allied Crops, &c., &c.

Trade Report.

(From the Board of Trade Journal and other sources.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

CLASSIFICATION OF ARTICLES IN CUSTOMS TARIFFS.

RUSSIA.

Note.—Pound = 35 lbs. avoirdupois. Rouble = 3s. 2d.

Materials for tanning known under the name of *algaborilla* and *tara*.—Category 108. Duty, 6 copecks per pound.

Saccharin.—Category 110. Duty, 2 roubles 40 copecks per pound.

NETHERLANDS.

Cocaine is taxed as soap not perfumed.

SWITZERLAND.

Note.—Quintal = 220'4 lbs. avoirdupois.

"Verdiline" (mordant used in dyeing).—Category 18. Duty, 2 francs per quintal.

Fluoride of aluminium and fluoride of sodium, analogous to cryolite.—Category 173. Duty, 60 cents per quintal.

SPAIN.

Note.—Peseta = 9'5d. Kilogramme = 2'204 lbs. avoirdupois.

Glucose is dutiable by gross weight. No matter what may be the form under which it is imported, it is subjected to duty under Category 249, viz., 30 pes. 80 cs. per 100 kilogrammes.

Subnitrate of bismuth.—Category 32. Duty, 10 cs. per kilogramme.

The product known as "Carbolineum avenarius."—Category 7. Duty, 41 cs. per 100 kilogrammes.

Nitro-benzine.—Category 32. Duty, 10 cs. per kilogramme.

Soap for household and industrial uses, but not adapted for the lubricating of machinery.—Category 206. Duty, 1 pes. per 100 kilogrammes.

UNITED STATES OF COLUMBIA.

Alterations in Import Duties.

Duty of 1 centavo.—Articles and stuffs used for refining metals by the chloric treatment.

Duty of 2½ centavos.—Quicksilver.

Duty of 5 centavos.—Dynamite for use in industry.

CUSTOMS TARIFF OF GABOON.

The following are the rates of import duty now levied on articles of chemical interest in the French Colony of Gaboon:—

Note.—Litre = 1'76 pints. Hectolitre = 22 Imperial gallons. Kilogramme = 2'204 lbs. avoirdupois.

Classification of Articles.	Rates of Duty now levied.
	Frs.Cs.
Oils, superior pure, olive and other.....	100 kilos. (gross) 6'00
Essences of turpentine, balsams, juices, &c....	Free.
Roots, herbs, leaves, flowers, fruits, and barks	Free.
Medicinal vegetables of any description, suitable for dyeing and tanning.....	Free.
Lime, cement, and plaster	100 kilos. (gross) 0'60
Pitch, tar, and coal tar.....	" " 0'50
Sea and rock salt	" " 0'40
All other chemical products.....	5 % <i>ad val.</i>
Alcoholic varnish	Hectolitre 100'00
Varnishes, other	100 kilos. (gross) 3'00
Colours of any descriptions	" " 3'00
Inks of every description	Pound 0'15
Soaps	100 kilos. (net) 20'00

Classification of Articles.	Rates of Duty now levied.
	Frs. Cs.
Alcoholic perfumes	Hectolitre 100 00
Non-alcoholic perfumes.....	100 kilos. (net) 16 00
Medicines, compounded.....	Free.
Vinegar	Litre 0 05
Manufactures of caoutchouc and gutta-percha	100 kilos. (gross) 20 00
Lucifer matches (wood)	100 kilos. (net) 12 00
Goods not otherwise distinguished.....	10 % ad val.

Note.—Goods of French origin imported in vessels of any nation benefit by a reduction of 60 per cent.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

ARGENTINE REPUBLIC.

The Drug Trade in Rosario.

According to the French Consul Rosario is, next to Buenos Ayres, the most important trade centre of the Republic. The tonnage of foreign vessels visiting the port has increased from 171,912 in 1880 to 1,032,783 in 1887. In that year the imports of prepared medicines were valued at 304,075 frs., of perfumery at 121,095 frs., and of raw drugs and chemicals at 877,080 frs. The imports of perfumery have increased elevenfold since 1880. Two-thirds of the whole is French perfumery. France also furnishes nearly one-third of the medicines, almost all patents, and about one-fourth of the chemicals. Yet there is not one single French drug-house in the town, the whole of that trade being in the hands of English, Swiss, Italian, and Spanish firms.

CHINA.

Insect Wax.

The steamer export of white wax (not bleached bees' wax, but the insect wax produced by the *Coccus Peltæ*) has increased greatly, writes the British Consul at Ichang. This curious and beautiful substance, though widely used in China, known to science, and repeatedly noticed in books on China, seems to be unfamiliar in our home market. Its dearthness has been against it, but the price has come down greatly. According to my information, the price at Kia-tzing Fu (in Szechuan, on the Min River, some 700 miles up river from Ichang) has lately been about 1s. per lb., avoirdupois. At Ichang there is at present no wholesale market for the article, but the wholesale cost, as yet for local consumption, is stated at about 1s. 3/4 per lb. Allowing for duty, freight, commissions, &c., the article might be placed on the home market at about 1s. 6d. per lb. In view of its beauty, hardness, and high melting point, it might be acceptable in the candle manufacture, to serve as a coating or otherwise.

Drug Exports.

The following are the exports of drugs from Ichang, one of the principal centres in the interior, during the last two years:—

Articles.	1887.		1886.	
	Lbs.	Value £.	Lbs.	Value £.
Galls	263,963	5,425
Medicines.....	..	63,915	1,978,363	47,794
Musk	2,900	53,469	1,180	19,696
Rhubarb	205,165	9,442	320,291	14,556
Safflower.....	111,208	12,302	75,913	8,314
Wax (Insect)	1,541,305	125,039	942,595	87,790

SIAM.

Gum Benjamin.

This gum, from the district bordering upon Tonquin, east of Luang-Prabang, is brought to the latter place by the Khmù tribe, who exchange it for manufactured goods with the Chinese dealers. The latter, in their turn, take it to Nong-Kai, the terminal point of

the trade road to the south, and from there, at great expense of carriage, to Korat, whence, by way of Sarabhoori and the Menam River, it is sent to Bangkok. In 1887 the exports amounted to 37,500 kilos., but it appears that shipments could be much more advantageously made by way of Saigon and by the Mekong River. If any French traders should penetrate from Tonquin to Luang-Prabang they will probably make gum benjamin one of their staple articles with the Laos country.

Stuck-lac.

This gum comes from the north and from the Laos country, and is sold on the Bangkok market in the same condition in which it is gathered, i.e., with the branches on which it is gathered adhering to it; the same lac, when finely broken and washed in hot water, is called seed lac. There is always a ready sale for this article on the local markets, as the Siamese dyers, who use it in their industry, compete for its acquisition with the export merchants.

SPANISH POSSESSIONS.

Patent Medicines.

A few patent medicines, notably Jaynes', Holloway's, and "Mother Seigel's Syrup," were formerly sold quite largely in Manila, but can come there no more unless the manufacturers consent to comply with the provisions of a decree issued in July 1888, which requires that the formula by which patent medicines are made shall be printed on the outside wrapper of each package, so that it can easily be read by all purchasers. This is considered by local druggists as an effectual bar to the entry of all patent medicines, as it is not probable that the manufacturers will consent to make public their formula except in very rare cases. When the supplies on hand are exhausted the medicine-takers will have to find new remedies for their ailments or give up being sick.

MISCELLANEOUS TRADE NOTICES.

EXPORT OF SICILIAN SULPHUR.

The *Handels-Museum* states, on the authority of a report by the Swiss Consul at Messina, that the price of sulphur in 1888 was slightly raised, in consequence of greater demands being made from abroad. This rise came at an opportune moment, for a maintenance of the prices paid during the last few years would have brought about the ruin of many of the proprietors of mines. There were exported from Sicily, in 1888, 350,000 tons of sulphur, as against 215,000 tons in 1887 and 330,000 tons in 1886. It is expected that the demand will continue to be in excess of the supply, and that a still greater rise in price will be the result.

The following table shows the manner in which the export of Sicilian sulphur to various parts of the world is distributed. The figures refer to the latter half of 1888. It will be observed that America takes nearly half the total export:—

	Kilogrammes.
England.....	18,921,199
France (South).....	24,490,800
France (North).....	347,700
Holland	1,741,600
Belgium.....	3,654,200
Germany (Elbe)	6,834,800
Germany (Baltic Sea)	858,900
Austria	3,957,700
Russia	12,503,200
Sweden and Norway.....	5,237,800
Australia	1,024,000
Spain	1,380,900
Portugal	231,400
Greece and Turkey	264,500
Italy	15,129,900
America	86,422,100
Other countries	186,400
Total	181,188,400

The amount in stock at Licata, Girgenti, and Catania was, at the end of December 1888, 211,905,500 kilogrammes, against 214,956,000 in 1887 and 243,237,000 kilogrammes in 1886.

CANADIAN PHOSPHATE INDUSTRY DURING 1888.

The annual report of the Canadian Department of Agriculture states, according to the *Canadian Gazette* for the 11th March last, that the total amount of phosphates shipped from Montreal during the season of 1888, according to the detailed returns furnished, was 14,432 tons, consisting of 14,392 tons in bulk, 384 bags, and 30 barrels of crude material. There were shipped to the United States 2,000 tons from the Ottawa Valley, 814 from the Kingston district, and 200 tons were used for home consumption, making a grand total of 17,446 tons. This shows a slight falling off, which is attributed by shippers to the difficulty of transportation from the mines. "I am credibly informed," says the Minister, "that an experiment was made during the past year with crude phosphate, which had been ground to an almost impalpable powder, on a field of potatoes in this district, half of it being treated

with this fertiliser and the other half with ordinary farmyard manure. The result was that the part of the field where the phosphate had been used yielded much larger and cleaner tubers than the other half, the soil in both cases being precisely the same." The above figures do not show the actual amount of phosphate mined during the year, but only what was actually shipped and consumed. The total output for 1888 is stated to be 23,200 tons, the difference between the output and the shipments being the amount left over at the mines waiting shipment next spring.

SOUTH AUSTRALIAN PIGMENT.

The *Adelaide Observer* for the 2nd February last says that about two years ago two deposits of pigment were discovered—one near Blackwood, in the hundred of Kuitpo, and the other near Wilunga. These paints have the advantage over the improved article, inasmuch as they can be mixed with oil without white-lead, and have been proved to be impervious to the action of air. The pigments were found in seams in a hole in apparently inexhaustible quantities, and there are twelve distinct shades of yellow, brown, red, and white. A company has been formed to place the colonial article on the market, and many tons of it have been sold already at a much lower cost than is paid for the imported paints. A substance similar to kalsomine has been named *australasomine*. Analysis of three samples of ochres resulted as follows:—Moisture at 100° C., 1.82, 1.92, 0.21; combined water, 6.48, 7.60, 4.00; silica, 11.20, 56.60, 65.20; oxide of iron, 38.40, 11.68, 5.76; alumina, 12.56, 19.12, 21.74.

DISCOVERY OF PETROLEUM IN SOUTH AUSTRALIA.

Respecting a discovery of petroleum springs in South Australia, the *Adelaide Observer* for the 2nd February last has the following note:—

"A valuable discovery of petroleum in a crude or liquid state has been found by Mr. A. Toechi, of Yorketown, and the Government have granted to him the exclusive right to search over an area of about 90,000 acres Crown lands at Southern Yorke's Peninsula to enable him to fix the position of the spring from which his discovery flows. Should his search be successful it will prove a valuable addition to the mineral wealth of the colony. Being situated close to the seaboard within 60 miles of Port Adelaide, the facilities for working the property will be very considerable. Estimates have been given by competent borers thoroughly conversant with petroleum in all its branches as to the cost of boring 1,500 feet, which will not exceed a pound a foot, and from information at Mr. Toechi's command he is very confident that he will be able to raise at any rate the crude oil at once. When Mr. Toechi has completed his search he will be entitled to take up an area of 10,000 acres for commercial operations."

STATISTICS OF SICILIAN BRIMSTONE.

We are indebted to Mr. A. S. Maclemonson for the following interesting statistics, showing the exports and prices per ton of 2,240 lbs. of brimstone, free on board, Sicily, during the past six years. Prices have ranged as follows:—

The total export from Sicily was divided as follows:—

—	1888.	1887.	1886.	1885.	1884.	1883.	—	1888.	1887.	1886.	1885.	1884.	1883.
United States..	128,265	89,419	98,590	99,378	94,920	96,620	Spain.....	3,433	5,873	5,890	2,243	3,920	5,242
France	52,983	56,222	51,280	58,264	65,098	63,692	Belgium	6,951	5,318	6,580	9,516	6,793	7,660
Italy	47,634	48,997	48,658	49,415	56,292	69,810	Holland	2,793	1,747	2,990	1,237	696	1,256
United Kingdom	35,634	30,097	30,236	33,402	40,760	41,788	Sweden.....	3,004	1,169	1,916	328	744	1,010
Greece,	5,809	18,370	19,697	13,664	7,063	10,494	South America	95	710
Portugal	15,851	16,587	39,943	17,769	11,018	15,298	Australia	885	600
Russia.....	22,013	13,411	10,570	13,420	12,831	10,113	Denmark	464	202	..	810
Germany.....	12,402	9,700	8,698	6,103	6,622	7,292	Total tons ..	347,775	341,302	329,446	314,582	314,058	335,392
Austria.....	8,942	6,702	5,800	5,965	6,037	4,915	Stocks in Sicily, Dec. 1st	167,569	199,200	202,392	193,700	181,500	193,707
Turkey	1,457	6,238	4,398	3,977	1,285	3,913							

Of the amount shipped to the United States during 1888, 72,173 tons were best unmined seconds, and 55,092 tons best thirds, against 66,710 tons of the former and 52,709 tons of the latter shipped during 1887.—*Engineering and Mining Journal*.

PRODUCTION OF STASSFURTH SALTS IN 1888.

Statistics of the production of potash salts at Stassfurth, which have just been published, show that the year 1888 was, on the whole, satisfactory. 16,571,600 centners of carnallite and 2,528,180 centners of kainite (and schornite) were obtained, and yielded 2,619,000 centners of potassium chloride and 600,000 centners of sulphates (potassium magnesium sulphate and potassium sulphate). In addition, 4,945,967 centners of kainite were sold for agricultural purposes. Large factories are in course of erection, which are to be open in the spring for the preparation of potassium chloride and potassium sulphate from the double salts of potassium and magnesium. Experiments are being continually carried on with a view to utilise the large quantities of magnesium chloride obtained in the mines.—*Industries*.

CAYOTA, A NEW TANNING MATERIAL.

This is a reddish-brown bark obtained from Mexico, where it is used for tanning thick sole leather, to which it gives great consistency and solidity. It contains about 25 per cent. of tannin, has a resinous odour, and is easily powdered. M. Villon, who has examined this new tannin, finds it to consist of yellow scales soluble in 15 parts by weight of water, and its molecular weight is equal to that of the tannin from oak bark. Although having a resinous odour, the bark or extract contains only a trace of resinous matter, and is therefore superior to Quebrado. It can also be used as a substitute for sumac.—*Industries*.

PLATINUM.

A noteworthy discovery has been lately made. Platinum has been found in place in the nickeliferous ore of Sudbury, Canada, by Professor F. W. Clarke. This discovery was made accidentally, in the course of determinative and analytical work upon the ore, which presents other peculiarities. While the amount found is of little or no commercial importance, it has a very great scientific significance, and is certainly something new. Platinum grains have been found in secondary rocks, such as recent sandstones, conglomerates, &c., but never before, so far as we are aware, in vein stuff, although it has long been looked for, and such an occurrence was to be expected. There is, therefore, always the chance that actual veins of platinum-bearing material, so often falsely reported, may actually be found, and that perhaps some of them may be of a paying grade. The number of localities and their wide distribution in this country points to such an outcome.—*Engineering and Mining Journal*.

PRODUCTION OF QUICKSILVER AT THE ALMADEN MINE (SPAIN) IN 1888.

	Flasks.
January	8,246
February	7,972
March	7,956
April	6,856
May	1,950
October	3,318
November	7,609
December	7,965
Total	51,872

We are indebted to the courtesy of Mr. J. B. Randol, of San Francisco, for this information concerning the production of the Spanish Almaden mine in 1888. It will be observed that the total production for eight months, the usual working period of the year, was 51,572 flasks, while all our Californian mines for 12 months in 1888 made only 33,250 flasks, or 18,622 flasks less than the product of the glorious mine of Almaden, rightly entitled to be called not only "The Jewel of the Crown," but also "The Jewel of all Mines."—*Engineering and Mining Journal*.

PROPOSED POTTERY WORKS AT JUBBULPORE.

Messrs. Burn and Co., the well-known contractors of Calcutta and Ranigunge, have, it is rumoured, applied for permission to take up land on a comparatively large scale in Jubbulpore for pottery works. The kaolin there has been analysed by experts in England, and found to be of the very best quality, while the quantity available is large. Hitherto there has been a difficulty about felspar, but it appears that this has now been discovered in considerable quantity near the Umaria coal mines. A pottery at Jubbulpore would not only give employment to a large number of persons locally, but would facilitate the construction of pipes for the Benares drainage works now in contemplation, and many other projects of a similar character that will soon be aboot in Northern India.—*Indian Engineer*.

PETROLEUM WORKS IN THE PUNJAB.

The Kattan Petroleum Works have, it appears, now passed beyond the experimental stage. An agreement has been definitely entered into to supply the works at the Khojak tunnel with about 34 million gallons of the oil. The wells, which are 42 miles from the

railway, have been connected with Babar Kuch on the Sind-Pishin line. The saving to the State from the use of the petroleum on the Khojak works alone will, it is estimated, be enough to cover all the cost of the Kattan experiments, and leave a balance of over five lakhs of rupees. And there is no reason to anticipate that the benefits of the apparently inexhaustible supply should end here. On the contrary, in a country like Beluchistan, where every stick of wood is worth its weight in silver, the demand for the new fuel must be great; and in addition to other advantages its use may be expected to put a stop to the destruction of the forests, which, until recently, was going on at an alarming rate. It is now intended to replace the expensive and wasteful system of camel carriage by laying a pipe-line from the wells along the Babar Kuch road; and should Government decide on sanctioning this, it may be confidently expected that the capabilities of Kattan will emerge once for all from the cold shade of neglect and scepticism in which an exaggerated idea of its remoteness has left it so long.—*Indian Engineer*.

THE EXPERIMENTS AT ROTHAMSTED.

It is satisfactory to observe that Sir John Lawes's munificent arrangement for devoting the sum of 100,000*l.* to the perpetuation of his valuable field and laboratory experiments is about to be completed. The sum will be placed in the hands of three trustees, who will have granted to them a lease of the laboratory and the experimental fields at Rothamsted, with power to purchase land for the purposes of the trust. The income of the fund will be handed over to a committee of nine persons, consisting of four Fellows of the Royal Society, one Fellow of the Linnean Society, two members of the Royal Agricultural Society, one Fellow of the Chemical Society, and the owner of Rothamsted for the time being. The committee will be appointed for five years, and will be eligible for reappointment. Sir John Thorold and Mr. Charles Whitehead have been appointed to represent the Royal Agricultural Society.

—*Standard*, 5.4.89.

CASTOR OIL v. OLIVE OIL FOR LUBRICATION.

The Italian Admiralty have recently caused to be carried out a number of experiments with a view to testing the comparative merits of castor oil and olive oil for lubricating purposes on board ship. From the results obtained they have given orders that henceforth all exposed parts of machinery are to be lubricated exclusively with castor oil, while mineral oils are to be used for cylinder and similar lubrication.—*Ironmonger*.

GERMAN METAL PRODUCTION IN 1888.

The metal production in the German Empire in the year 1888 is reported as follows:—Zinc, 133,224 tons, average value, 327 m. 9 p. per ton (1887, 130,693 tons and 280 m. 45 p.); block lead, 93,995 tons, average value, 256 m. 18 p. per ton (1887, 91,929 tons and 236 m. 99 p.); block copper, 29,872 tons, average value, 1,461 m. 11 p. (1887, 29,202 tons and 877 m. 24 p.); zinc ores, 667,760 tons, average value, 20 m. 59 p. (1887, 900,712 tons and 11 m. 13 p.); lead ores, 161,775 tons, average value, 102 m. 83 p. (1887, 157,570 tons and 101 m. 6 p.); silver, 406,527 kilos, average value, 126 m. 49 p. per kilo. (1887, 367,633 kilos, and 130 m. 99 p.); gold, 1,810 kilos, average value, 2,791 m. 13 p. per kilo. (1887, 2,251 kilos, and 2,799 m. 85 p.).—*Ironmonger*.

MANGANESE ORE IN NEW ZEALAND.

Manganese ore has been discovered in large quantities, and of splendid quality, near Dunedin, from which a valuable export trade is expected to result. A sample was sent to London, and a cable message has been received placing a value on it that leaves a large margin for profit. The quantity of this ore exported from New Zealand up to 1885 amounted to 12,000 tons, valued at £3,000*l.*, but of late years the shipments have fallen off largely. It came chiefly from the Bay of Islands, and was not nearly so pure as the present discovery, which assays 80 to 90 per cent. of pure peroxide.—*Ironmonger*.

THE YTTRIA MINERALS.

In connexion with the subject of the rarer minerals at the last meeting of the New York Academy of Sciences, Mr. George F. Kunz said that during the last year large quantities of gadolinite were sent from near Bluffton, in Llano County, Texas, 22 miles from Burnett. The occurrence of this gadolinite was somewhat similar to that of allanite in Amherst County, Virginia; it has more than ordinary interest, from the fact that it contains from 40 to 50 per cent. of yttria. About 1,000 lb. were found in a single pocket, associated with xenotime, cerussite, and xenotime. One crystal of gadolinite was exhibited weighing 11 lb.; another was found weighing 13 lb., and a group weighing 40 lb. The productions of this locality exceed in quantity and size of crystal anything yet obtained.—*Engineering and Mining Journal*.

AMERICAN PAPER GOING TO ENGLAND.

It may be considered remarkable, and it will doubtless create some excitement, and perhaps dismay, among the paper-makers of Great Britain, to learn that an English journal of importance has offered to contract with one of our leading American manufacturers of paper for its supply of paper for one year. This offer results from a trial of the paper, and is an earnest of the fact that we are able to produce goods which, as to quality and to price, will meet the competition of foreign manufacturers, even on the latter's own ground. Nor is this likely to be the only instance of such a contract, for it is intimated that one more is pending, and that still another English journal is ready to use American paper.—*Engineering and Mining Journal*.

AMERICAN OZOKERITE.

A company has been formed, under the laws of New York State, to develop large deposits of ozokerite, a natural paraffin wax existing in the Wasatch mountains of Utah Territory, about 113 miles east of Salt Lake City. These mines are said to contain the only deposits of this mineral known to exist outside of Galicia, in Austria, whence the entire world's supply of this product has, until recently, been obtained. The uses of this mineral are constantly enlarging, and in this country alone the consumption amounts to 500 tons yearly. The price of refined ozokerite, commercially known as ceresin, ranges from 20 c. per lb. for chemically pure white, down to 6 c. per lb. for crude black of a poor quality. The company proposes to mine 1,500 tons of wax yearly, and pay 7 per cent. on a capital stock of 1,250,000 dols. The first shipment from the American mines arrived in New York in January this year, and attracted considerable comment. — *Engineering and Mining Journal*.

PAPER FROM SUGAR CANE.

The *Revue Scientifique*, of Paris, states that at New Orleans, samples of bleached paper of the quality made from sugar cane are being exhibited. Having regard to the low value of sugar, and the increasing demand for paper, it might be worth while to introduce this industry into places where the sugar cane is grown.

BELGIAN PRIZES TO CHEMISTS.

The Belgian Academy of Sciences have published the list of prize queries proposed for the year 1890. The following are of interest to chemists and physicists: — (1) Establish, by means of new experiments, the theory of the reactions presented by bodies in what is called the nascent state. (2) Expose and discuss, with the help of new experiments, the works relating to the kinetic theory of gases. The prizes offered are gold medals, worth 800 frs. for the first, and 600 frs. for the second. Memoirs may be written in French, Flemish, or Latin, and must be handed before August 1, 1890, to M. Liagre, Perpetual Secretary, Palais des Académies, Brussels. The usual academic conditions—that is, the enclosure of the writer's name in an envelope marked with a motto repeated on the memoir—are of course to be observed.

CHEMISTRY IN NANCY.

By a law, published on April 11, the City of Nancy has been authorised to borrow 20,000*l.* for establishing a chemical and an anatomical institute. The rate of interest must not exceed $\frac{1}{2}$ per cent., and the principal is to be refunded within forty years.

ADULTERATION OF FOOD IN BELGIUM.

See Board of Trade Journal for April, p. 464.

SUPERPHOSPHATES AS MANURE.

Some quite unusual results were brought out in experiments on an oat crop on a hill farm near Exmoor, as described by Mr. T. D. Acland in the "Journal" of the Bath and West of England Agricultural Society. The oats were sown after four years of grass, which succeeded a root crop fed on the land. There were duplicate plots in each case, and the yield shows the average. Where no manure was used 11 bushels 23 lb. of bread corn were produced; on plots dressed with 1 cwt. of sulphate of ammonia, 40 bushels; where 1 cwt. of nitrate of soda was used, 40 bushels 7 lb.; after 3 cwt. of superphosphate, 49 bushels 32 lb.; from the application of 1 cwt. of nitrate of soda and 3 cwt. of superphosphate, 58 bushels 12 lb.; and as the result of using 1 cwt. of sulphate of ammonia and 3 cwt. of superphosphate, 60 bushels. It is clear that the land was so deficient in phosphates that no extra yield beyond that of the unmanured plots could be obtained from the use of nitrogenous manures alone. The phosphatic manure by itself gave a large increase of corn, and that increase was more than doubled when nitrogen was added. On another farm in Cornwall the same nitrogenous manures produced a small increase in the oat crop, but not sufficient to be remunerative; while the addition of 3 cwt. of superphosphate to the nitrate of soda or sulphate of ammonia brought forth double the yield of the adjoining unmanured plots, and paid well. These results, like those of the Norfolk experiments, recently referred to, show in a striking manner the need of trials of the kind in all parts of the country. — *Standard Agricultural Reports*.

STATISTICS.

BOARD OF TRADE RETURNS.

The trade and navigation returns for March are thoroughly satisfactory. An increase of 11 per cent. has taken place in the imports, and the exports have gone up 12 per cent., so that the apparent hang-back of February is now more than made good. Prices to some degree account for this improvement, but not so far as to neutralise the importance of the gain in volume which the foreign trade of the country is now showing. Among imports the

solitary class showing a decrease in value is "metals," and the falling off there is not due, as might seem probable, to the reduction in the price of copper, but to tin, which compares unfavourably, both in quantities and price, with the figures of a year ago. The export figures are uniformly good, for the slight decrease in the value of articles of food and drink exported may be let pass unnoticed. A revival is exhibited under woollen and worsted manufactures, and "metals and ironwork" and "machinery and mill work" continue to display greater prosperity than they have done for years. This prosperity is, in part, the result of the liberal lending of the country to foreign countries, and of the large amount of capital poured into South Africa by mining companies; but Continental Europe is also a better customer than it was, for steam engines at least. For the first quarter of the year the imports have amounted to 106,526,000*l.*, an increase of 9,617,000*l.*, or 9½ per cent. on the corresponding quarter of 1888; and the exports to 60,470,000*l.*, an increase of 3,847,000*l.*, or 6½ per cent. March has, therefore, done much better than the average of the quarter. Subjoining are the usual tables for the month:—

Imports.

Compared with March 1888.

	Total.	Increase.	Decrease.
	£	£	£
Animals living.....	618,755	145,441	..
Articles of food and drink (duty free)	10,917,240	1,921,447	..
Articles of food and drink (dutiable)	2,341,522	123,998	..
Metals.....	1,936,125	..	312,694
Chemicals	1,204,573	187,267	..
Raw materials for textile manufacturers.....	9,912,335	594,798	..
Raw materials for other industries	2,698,190	463,819	..
Manufactured articles	5,771,197	454,697	..
Miscellaneous articles	1,333,957	56,289	..
	36,225,883	3,947,756	312,694
		312,694	
Net Increase.....		3,635,062	

Exports.

Compared with March 1888.

	Total.	Increase.	Decrease.
	£	£	£
Articles of food and drink...	793,644	..	43,885
Raw materials	1,326,189	340,713	..

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

- 4687, T. W. Duffy. Apparatus for transmitting heat to fluids, applicable also for condensing or cooling. March 18.
 5155, J. Anderton. An improved polariscope for the use of brewers, sugar manufacturers, analysts, and others. March 26.
 5156, J. W. Wailes. Improvements in liquid valves for produce and other gases and air. March 26.
 5197, J. C. Mewburn.—From La Société des Générateurs à Vaporisation Instantanée (Système Scrpellet), France. Apparatus for generating steam. March 26.
 5326, T. F. Shillington and J. A. Hanna. Appliances for heating liquids by steam. March 28.
 5373, P. W. Turner. Improvements in wooden vessels for carrying or holding corrosive substances. March 29.
 5493, M. W. Household. Apparatus for raising or forcing liquids. March 30.
 5497, M. W. Household. Apparatus for raising or forcing hot liquids. March 30.
 5539, H. Bernzer. Centrifugal separating machines. Complete Specification. April 1.
 5592, W. L. Wise.—From Escher Wyss and Co., Switzerland. Improvements in the manufacture of clear ice, and in apparatus employed therein. April 2.
 5731, G. C. Webb. An improved valve for gases under pressure. April 2.
 5752, R. W. Holden. Heating apparatus. April 4.
 6102, P. Cornish, jun. Improved means for drying or desiccating substances or materials. April 9.
 6217, W. Bergh. Centrifugal machines for the separation of fluids of different specific gravities. April 11.
 6242, R. Haig. Mechanical retorts for the treatment of animal, vegetable, and mineral matters. April 12.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

- 4402, W. P. Thompson.—From The Porcelain Dental Art Company. Hydrocarbon furnaces. March 27.
 7061, I. S. McDougall, J. T. McDougall, R. K. Hartley, and T. Sudden. Boilers or vessels lined with lead or other acid-resisting metal or alloy. April 17.
 7411, A. Horn. Saccharometers. March 27.
 7674, H. Lane. Method and means for measuring air, gas, and other fluids. April 3.
 7768, S. Spencer and J. S. Lord. Method and apparatus for forcing and drawing chemical and other liquids. April 3.
 8053, G. Fletcher.—Partly from G. Brocklehurst. Evaporating pans. April 3.
 8064, F. W. Scott, jun.—From A. Freitag. Tubular vacuum pans. April 17.
 8078, J. Watt. Apparatus for causing or increasing circulation in liquids during ebullition, and for removing sediment therefrom. April 10.
 8290, J. Y. Johnson.—From La Société Française des Alcools purs. Apparatus for separating liquids having different boiling points. April 3.

1889.

- 5644, J. J. Meldrum. Apparatus for distributing air or gases to liquids. April 10.
 5963, W. Prickarts. Reverberatory and roasting furnaces. April 17.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 4686, J. S. Balfour and J. P. Houston. Improvements in the manufacture of fuel from coal slack and similar substances, and in apparatus used therein. March 18.
 4726, R. A. Gilson. Improved means of utilising the waste heat of a gas-flame for warming purposes generally, and for increasing the luminosity of the flame. March 18.
 4807, W. J. Taylor. Improvements in the art of firing furnaces and converting solid fuel into gaseous fuel, and of apparatus for the conduct thereof. Complete Specification. March 19.
 4858, J. Grossmann. Improvements in apparatus for purifying coal-gas. March 20.
 4820, D. Irving and A. Cochey. Improvements in apparatus for extracting ammonia, sulphur, and other impurities from coal gas. March 20.
 4880, J. Bead and G. C. Fowler. Improvements in night-lights and in the method of manufacturing the same. March 20.
 4942, H. H. Yates. Improvements in spirit or vapour torches for lighting purposes. March 21.
 4920, P. Tarrington and D. S. McDonald. Improvements in portable apparatus for manufacturing gas. Complete Specification. March 21.
 4955, Birt's Oxygen Company and K. S. Murray. Improvements in or connected with apparatus or means employed in producing oxygen and the like. March 21.
 5108, J. Somerville and A. Allan. An improved hydraulic main for gas manufacture. March 25.
 5332, T. H. Gray. Improvements in the treatment of mineral oils. Complete Specification. March 25.
 5334, G. H. Turnbull. Improvements in the trays or grids of gas-purifying apparatus. Complete Specification. March 25.
 5345, J. H. R. Dinsmore. Improvements in the manufacture of gas for illuminating and heating purposes, and in or connected with apparatus therefor. March 26.
 5381, W. M. Cosh. Improvements in apparatus for the manufacture of illuminating or heating gases. Complete Specification. March 26.
 5380, A. J. Boulton.—From H. G. Weber, United States. Improvements in the manufacture of artificial fuel. March 29.
 5447, W. Boggett. Improvements in obtaining light. March 29.
 5535, G. Bamberg. Automatically maintaining the internal temperature of retorts at a full red-heat, and also preventing use of temperature beyond full red-heat. April 2.
 5697, B. F. Kelly, J. H. Spencer, and H. Spencer. Improvements in fuel blocks. April 2.
 5880, W. C. Hicks. An improved apparatus for admitting oxygen, air, or other gas or gases into coal-gas main in proportion to the make of such gas, and for varying this proportion at will. April 6.
 5974, D. S. Hawks.—From E. L. Brady, United States. An improved anticorrosive lubricant and lubricating vapour for carbon-disulphide and other vapour motors. April 8.
 6079, W. Hubbard. Improvements in or relating to compressed fuel blocks. April 9.
 6090, F. H. Briggs. Improvements in or relating to apparatus for the manufacture of water-gas. April 9.
 6130, S. Fox and E. Blass. A method of and apparatus for adding volatile substances to gases. April 10.
 6131, S. Fox and E. Blass. Improvements in apparatus for and in the manufacture of water-gas. April 10.
 6263, W. Schooling. Improved means for the filtration of the products of combustion. April 12.
 6325, R. B. Main, A. P. Main, and H. Darwin. Improvements in refractory balls or humps for incandescent gas fires. April 13.
 6326, R. B. Main, A. P. Main, and H. Darwin. Improvements in gas fires. April 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

- 6019, J. Thornecloe. Manufacture of fire-lighters. April 3.
 7490, T. H. Lien.—From J. Flannery. Process and apparatus for making illuminating and heating gas from water in combination with carbonaceous substances. April 17.
 13,679, S. Pitt.—From D. Aikman. Treatment of peat. April 3.

1889.

- 411, J. S. Chapman. Appliances and compositions for lighting fires, &c. April 17.
 4124, J. Mactear. Increasing the luminosity of ignited gas. April 17.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

4825. J. Inray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France. Manufacture of azo colouring matters. March 15.

5032. J. Inray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France. Manufacture of colouring matters giving grey, brown, and analogous tints. March 22.

5079. B. Willecox.—From The Farbenfabriken vormals F. Bayer & Co., Germany. New or improved manufacture of periodides of phenols and salicylic acid. March 23.

5549. O. Inray.—From The Farbenfabriken vormals Meister, Lucius, and Brünig, Germany. Improved manufacture of green and bluish green colouring matters. April 1.

5695. E. de Pass.—From Messrs. Ewer and Pick, Germany. Improvement in the manufacture of azo colours. April 2.

5785. J. Y. Johnson.—From F. von Heyden, Germany. A process for the production of oxymethoxybenzoic acids. April 4.

COMPLETE SPECIFICATION ACCEPTED.

1888.

7997. H. H. Lake.—From K. Oehler. Manufacture of colouring matters. April 10.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

4991. J. Yates and G. Kay. Improvements in open soapers for dunging and soaping fabrics. March 22.

5582. A. W. Montgomery. Improvements in the treatment of sisal hemp. Complete Specification. April 2.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

1851. R. Philips. An improved apparatus for bronzing, colouring, or otherwise ornamenting and dusting paper or other material. March 20.

4865. S. Spencer and E. Barlow. Improvements in the method of and means for bleaching and dyeing or otherwise similarly treating raw, spun, or woven fibres. March 20.

1870. G. Young and F. Pearn. Improvements in mechanism or apparatus for dyeing and bleaching cotton, wool, silk, and other fibrous materials in the raw and manufactured, or partly manufactured, state. March 20.

5125. W. H. Caldwell. Improvements in and connected with the sizing of paper. March 25.

5590. E. Bentz, C. Edmeston, A. Edmeston, and E. Grether. Improvements in scouring or cleansing and bleaching textile fabrics, warps, and yarns formed of cotton or other vegetable fibres, and in apparatus to be used for the purpose. April 2.

5995. D. G. FitzGerold. Improvements in bleaching by the agency of chlorine and certain of its compounds. April 8.

COMPLETE SPECIFICATION ACCEPTED.

1888.

18773. R. P. Frist. Linings for bleaching keirs, vats, dye-tanks, &c. April 17.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

4674. D. Herman. Improvements in apparatus for use in the manufacture of sulphate of soda. March 18.

4692. W. Law. Improvements in and relating to the evaporation and concentration of caustic soda lyes and other liquids, and appliances therefor. March 18.

4701. S. Daw. A method of treating waste or spent sulphuric acid pickle produced in the manufacture of tin,terne, and black plate. March 18.

4723. F. Maxwell Lyte. The conversion of ammoniac chloride into ammonia and chlorine or hydrochloric acid. March 18.

5355. H. Kenyon. Improvements in utilising and heating Leblanc waste and other matters. March 23.

5088. J. Plummer. Improved ammonia process to manufacture soda and bleaching-powder. March 25.

5224. M. Cannon. Improvements in the manufacture of acetic acid. Complete Specification. March 26.

5225. R. Dormer. Improvements in or relating to obtaining chlorine. March 26.

5340. G. A. H. Gabet. Process of manufacture of ammoniacal calcic phosphate. March 28.

5341. G. A. H. Gabet. Process of manufacture of potassic and sodic alkalis. March 28.

5779. J. W. Kynaston and J. Sutherland. Improvements in the treatment of the recovered ash of paper mills. April 4.

6945. A. Smith. A process for manufacture of nitrate of potash from nitrate of soda. April 9.

6118. H. H. Lake.—From J. L. Alberger, H. Williams, and L. R. Alberger, United States. Improvements in apparatus for the manufacture of salt. Complete Specification. April 9.

6172. F. M. Lyte. Improvements in the production of magnesic chloride and of magnesic oxychlorides. April 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

5086. W. J. A. Donald. Manufacture of chromates. April 3.

5371. G. J. Geary.—From A. Keiller. Manufacture of sulphide of zinc for pigments or other purposes. April 17.

5353. L. G. G. Daudenart. Extracting magnesia from sea water, and apparatus therefor. April 10.

5351. G. S. Page. Process and apparatus for obtaining anhydrous liquid ammonia. April 17.

9763. J. S. Rigby and A. McDonald. See Class IX.

9858. J. Lowe. Manufacturing sugar of lead. April 17.

17,969. H. H. Lake.—From O. B. Peck. The desulphurisation of ores, and decomposition of metallic salts and similar compounds. April 3.

1889.

1189. E. Augé. Manufacture of salts of alumina. March 27.

4286. J. Winskill, jun. Kiln for burning limestone. April 17.

4325. G. E. Carleton. Method and apparatus for calcining limestone. April 17.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

4759. J. R. Kempe. Improvements in the method of and apparatus for moulding fireclay and earthenware closet pans, lavatories, baths, sinks, urinals, syphons, gullies, stretch-traps, basins, jugs, and other fireclay and earthenware articles. March 19.

5048. D. Rylands. Improvements in moulds for forming bottles by the pressing and blowing process. March 23.

5138. A. W. Turner and G. Tomkinson. See Class X.

5691. J. A. Edwards. An improved method and apparatus for supporting articles of earthenware or porcelain whilst being fired. April 2.

5775. J. D. Denny. An improvement in facing bricks, tiles, terracotta, &c., in various patterns and colours, glazed or otherwise, and appliances for making the same. April 4.

5922. J. Rhodes. An improvement in the manufacture of china and earthenware saucers. April 8.

6088. J. Gimson and C. Challinor. A connecting socket pin for supporting china, earthenware, and tiles in glost ovens and enamelling kilns. April 9.

6247. J. Howie. Improvements in enamelling or glazing pipes, traps, and like articles made of earthenware or clay. April 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

3598. C. E. Mumford. Tiles for malt-kiln floors. April 10.
 6905. J. M. Day. Manufacturing glass bottles. April 17.
 8518. A. E. Letalle and P. Billing. Photographic stained glass. April 17.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

4683. H. Edis. Fireproof and noncombustible asbestos wall and ceiling papers. March 18.
 4806. Sir E. J. Harland, Bart. Improvements in the manufacture of elastic tiles. Complete Specification. March 19.
 4848. T. Hydes. Improvements in the manufacture of cement. March 20.
 4946. R. R. Clinis. Improvements in bricks. March 21.
 5133. C. J. Howe. The production of a cement or plaster suitable for rapid fireproof plastering, and for all other purposes for which Keen's and other similar cements or plasters are used, and which is capable of being produced at about the price of ordinary plaster of Paris. March 23.
 5157. J. W. H. James. Improvements in the manufacture of cement. March 26.
 5185. H. Ghurshkovitch. Improvements in cement pipes and apparatus for making the same. March 26.
 5190. St. G. T. C. Bryan. Improvements in and relating to the treatment of slag for a variety of important uses, such as making it cellular for pavements, walls, and the like. Complete Specification. March 26.
 5205. H. L. Boulton and S. H. Leech. Improvements in the manufacture of blocks of terra-cotta and like materials, and in machinery for that purpose. March 26.
 5363. B. Rhodes. An improved non-corrosive material, suitable as a cement packing or covering to resist acids. March 28.
 5412. T. K. Ferguson. Improved combination of ingredients for use as mortar, plaster, and the like for building purposes. March 29.
 5919. W. S. Lea and H. M. Lynam. Improvements in the manufacture and composition of refractory or fire-resisting cement or cements. April 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

5808. A. C. Ponton. Manufacture of artificial stone. April 10.
 6807. P. Stuart. Pavements. April 10.
 7456. J. S. Rigby. See Class XVI.
 7618. W. Ross. New form of brick for building purposes, called "the Culloden partition brick." April 10.
 7915. A. Fleiner, H. Haenschild, and A. Bauermeister. Manufacture of Portland cement and apparatus therefor. April 10.
 7925. H. T. Holloway and H. Holloway. Block floors or pavements. April 3.
 8879. T. C. Fawcett and T. Castle. Combination of machinery for mixing or making cement. April 17.
 9763. J. S. Rigby and A. MacDonald. Manufacture of cement from the calcium sulphide waste of Leblanc soda manufactories. March 27.

1889.

2632. J. Sugden. Artificial building materials. March 27.
 2919. C. C. Gilman. Fireproof ceilings. April 3.
 2921. C. C. Gilman. Fireproof floors and roofs. April 3.
 2922. C. C. Gilman. Fireproofing wood or iron posts or columns. April 3.
 2923. C. C. Gilman. Construction of fireproof floors and ceilings. April 3.
 2926. C. C. Gilman. Pavements or side walks. April 3.
 3288. E. Prime. Apparatus for grinding cement, &c. March 27.
 3875. R. Haddon. --From S. E. Haskin. Seasoning or preserving woods. April 17.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

4719. T. R. Jordan. Improvements in machinery or apparatus for the extraction of gold and silver from their ores. March 18.
 4731. W. C. Roberts-Austen, E. J. Ball, and A. Wingham. Improvements in the purification of iron and steel. March 18.
 4765. T. H. Johns. Improvements in tinning and finishing tin andterne plates, and an appliance used therefor. March 19.
 4832. T. Sharp. Improvements in and connected with the manufacture of sheet iron. March 20.
 4836. T. Doughty. A new and improved method of casting and treating steel ingots. March 20.
 4882. P. C. Gilchrist. Improvements in the manufacture of copper. March 20.
 4956. C. Jones. Improvements in the treatment of steel. Complete Specification. March 21.
 5027. G. W. Webber, J. T. Niblett, and T. A. B. Carver. Improvements in the extraction of mercury from its ores. March 22.
 5037. D. Owen. Improvements in means or apparatus for the purification of molten tin or its alloys. March 23.
 5078. A. E. Barthel. Improved process for the production of fixed or detachable deposits of homogeneous iron in any form, size, or thickness from iron ores or steel, or iron in any form. March 23.
 5082. E. C. Miller. --From The Magnolia Anti-friction Metal Co., United States. Method of preparing or treating metals for the manufacture of compositions or alloys for anti-friction purposes. March 23.
 5089. J. Smith. Improvements in rollers for rolling iron, steel, or other metals. March 23.
 5138. A. W. Turner and G. Tomkinson, Birmingham. Improvements in annealing furnaces. March 26.
 5195. J. Lones, C. Vernon, E. Holden, and R. Bennett. An improvement or improvements in the manufacture of buffer iron or steel for the buffer cylinders of railway carriages, trucks, and waggon. March 26.
 5224. E. B. Parnell. Improvements in the extraction of metals from their ores and in apparatus therefor. March 26.
 5351. J. Lones, C. Vernon, E. Holden, and R. Bennett. Improvements in making box piles for the production of blooms and bars and other forms of iron or steel, or mixtures of iron and steel. March 28.
 5358. M. Scott. Improvements in casting ingots or other masses of metal, and apparatus for that purpose. March 29.
 5578. J. H. Pollok. Improvements in the wet method of extracting gold. April 2.
 5639. F. Knaffle. An improved process and apparatus for the manufacture of steel ingots. Complete Specification. April 2.
 5667. J. H. Darby. Improvements in the manufacture of ingot iron or steel, and the simultaneous production of a highly phosphoric slag. Complete Specification. April 2.
 5669. C. M. Hall. The production of aluminium. Complete Specification. April 2.
 5670. C. M. Hall. The production of aluminium and alloys thereof. Complete Specification. April 2.
 5914. R. E. Green. The production of aluminium. April 6.
 5938. W. S. Simpson. Improvements in connexion with the casting of metals, and in moulds and appliances therefor. April 6.
 5989. P. Schroedter and A. Schroedter. Method of purifying quicksilver. April 8.
 6023. C. T. J. Vautin. An improved process for the amalgamation of gold or other metals capable of amalgamation. April 8.
 6026. F. W. Rose. --From T. K. Rose and D. Dennes, United States. An improved method of and apparatus for treating ores. April 8.
 6035. W. Kloen. Nickel-silver coating tins for canning provisions. April 9.
 6070. S. McCloud. Improvements in the manufacture of bars and rounds of steel and iron and in apparatus therefor. April 9.
 6116. J. B. A. Simmonet and S. W. Cragg. Improvements in and connected with the extraction of gold or silver, or both, from their ores, or other matters containing gold or silver, or both, and in apparatus to be employed therein. April 9.
 6278. J. E. Sherman. Improvements in or relating to open-hearth furnaces. April 12.
 6387. L. Q. Brin and A. Brin. An improved process for the production of metallic aluminium and certain by-products. April 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

7257. F. Fenton and R. J. Partridge.—From J. Woolford. Apparatus for preventing loss in the smelting of ores, metals, or compounds of zinc or other oxidisable metallic substances and ores or wastes of them. April 10.

8668. M. Settle. See Class XXII.

8925. R. P. Wilson, F. J. Wall, F. A. Thurston, T. L. Bibbins, and W. L. Flanagan. Pneumatic process of manufacturing iron, steel, and other metals. April 17.

9783. A. Feldman. Production of metals of the earths and alkaline earths. April 10.

11347. J. Williams and G. L. Morris. Finishing metal plates coated with tin, terne, or other alloy. March 27.

12459. O. Hurry.—From V. Riatti. Production of sulphide of aluminium and aluminium. April 17.

16451. J. Ewart. Protecting surfaces of iron and steel from oxidation. March 27.

1889.

2965. W. H. Melaney. Manufacture of safe and armour plates. April 10.

3098. R. H. Braudon. Process and apparatus for hardening steel. April 10.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

4871. H. A. Seegull. Improvements in the electrolytic process of obtaining copper, zinc, and tin. March 20.

5093. W. J. S. Barber-Starkey. Improvements in electric batteries. March 25.

5107. E. M. H. Audreoli. Improvements in electro-chlorinating auriferous ores. March 25.

5116. T. Pense. Improved electrical storage battery or accumulator. March 25.

5176. E. A. Sperry. Improvements in or connected with electrical installations. Complete Specification. March 26.

5251. R. Kennedy. Improvements in generating and storing electric energy. March 27.

5816. W. E. Laugdon. Improvements in electrical accumulator or secondary batteries. April 5.

5839. T. H. Allum, G. C. Fricker, and J. R. Bainton. Improvements in dynamo-electric machines. April 5.

6112. P. A. Newton.—From W. Main, United States. Improvements in secondary batteries. Complete Specification. April 9.

6119. J. J. Shedlock and R. Western. Improvements in thermoelectric batteries. Complete Specification. April 9.

6286. D. Urquhart and W. Bates. Improvements in secondary batteries. April 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

926. C. Hoepfner. Electrolytic production of metals. March 27.

5162. W. M. Mordey. Electric generators. April 10.

6386. W. E. Ayerton, J. Perry, and D. Cook. An electro-dynamic relay for constant or varying currents. March 27.

6961. G. A. Nussbaum. Automatic electric batteries. April 17.

7876. B. Willeox.—From B. A. Abakanowicz and A. d'Arsonval. Electric batteries. April 3.

8039. A. Leclercq and A. Vansteenkiste. Transformation or conversion of electric currents. April 3.

9381. A. Inschenetzky. Electric batteries. April 3.

1889.

485. H. E. Newton.—From D. Pidrálita. Electric generators. April 3.

2949. E. D. Cross. Galvanic batteries. March 27.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

5028. J. Annall. An improved lubricating compound. Complete Specification. March 22.

5353. W. G. Smith. Improvements in or appertaining to the manufacture of soap. March 28.

5622. J. Pearson. Improvements in treating cotton-seed oil mucilage to obtain soap. April 2.

5680. G. R. B. Kempton. Blue soap for laundry washing. April 2.

5908. M. Matthews. Improvements in the manufacture of soap. April 6.

6225. A. H. G. Eichelroth.—From A. Findenigg, Austria. Manufacture of stearic and oxystearic acids from fish oils, more especially the residue of train oil. April 11.

6291. O. C. Hagemann. Improvements in the manufacture of soap. April 12.

6551. O. C. Hagemann. Improvements in the manufacture of soap. April 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8262. C. A. Morris. New preparations from vaseline. April 3.

8604. C. A. Stitt. Manufacture of soap. April 17.

9187. E. A. Ashley. Metal and marble cleaning soap. April 10.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

4724. F. Maxwell Lyte and C. H. Maxwell Lyte. Improvements in the production of basic salts of lead. March 18.

5344. F. Greening. The manufacture or production of an improved material or compound adapted for use as a substitute for ivory, horn, whalebone, india-rubber, gutta-percha, and other materials, also as a coating or varnish for waterproofing and other purposes. March 28.

5349. J. Freemont. An improvement in the manufacture of coloured sealing-wax. March 28.

5368. H. E. Kent. The British disinfecting adhesive paint. March 28.

5380. G. R. B. Kempton. Sapphire crystal-blue for laundry purposes. March 29.

5547. P. A. Abrahamson. Sealing-wax compounds for bottles, parcels, letters, and the like. April 1.

5550. E. Edwards.—From P. Charrier and E. Dubueq, France. An improved copying ink. April 1.

5763. M. Gaugi and J. Mossner. An improved solution for rendering cloth, felt, paper, and the like waterproof. Complete Specification. April 4.

5792. L. E. Andes. An enamel or paint having disinfecting properties. Complete Specification. April 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

5371. G. J. Geary.—From A. Keiller. See Class VII.

7398. R. Avenarius. Treatment of tar oils for use as wood-preserving paints or coatings. March 27.

7708. L. H. Goggs and T. T. Irvine. Bronze or other metallic paints. April 3.

8738. E. A. de Lisle. Manufacture of a vegetable black for decolourising purposes, and apparatus therefor. April 17.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

4959. F. Weintraud.—From C. Weintraud, jun., Germany. Novel method of preparing leather to produce a velvety exterior surface. March 20.

5671. C. W. Cooper. Process of and apparatus for treating hides, skins, or scraps in liquids. Complete Specification. April 2.

5672. C. W. Cooper. Method of treating hides, skins, or scraps in liquids. Complete Specification. April 2.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8221. N. F. E. Rapenud. Artificial leather. April 17.

2038. F. W. P. Swinborne. Treating hides or skins to obtain gelatinous matters. April 17.

1889.

3904. G. Johnson and H. Clarke. Sole leather. April 19.

XV.—AGRICULTURE, MANURES, Etc.

APPLICATIONS.

4862. F. Hocking. Improvements in and in the manufacture of manure, and apparatus connected therewith. March 20.

5703. H. J. Kirkman. Improvements relating to the treatment and utilisation, for agricultural and other purposes, of bisulphate of soda or nitre cake. April 2.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

4741. H. Barker. A novel method or process for the manufacture of gluten and starch. Complete Specification. March 19.

4941. P. Litvinenko. Improvements in the manufacture of sugar. March 20.

4942. P. Litvinenko. Improvement in apparatus for use in the manufacture of sugar. March 21.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

7456. J. S. Rigby. Utilisation of the lime mud refuse of sugar and other industries for cement, &c. April 10.

8052. G. F. Redfern.—From W. P. Abell. Centrifugal machines for use in the manufacture of sugar. March 27.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

5564. W. P. Thompson.—From La Société Générale de Maltose, Belgium. Improvements in or relating to the manufacture of maltose or to the fermentation of mylaccous matter. April 1. Antedated (under Pat. Act, 1883, sec. 103) 28 November 1888, being date of application in Belgium.

5647. C. Schmitt. Improvements in and connected with the purification of raw spirit in order to produce highly rectified spirits of wine, and apparatus therefor. April 2.

5689. J. E. Reynolds. Improvements in the utilisation of the carbonic acid gas derived from fermentation. April 8.

5981. G. Reinighaus. Improvements in the preparation of malt. April 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8522. A. G. Ferica and A. Ezeimann. Clarifying beer, wine, and other fermented or fermenting liquids. April 17.

11,189. J. Mitchell. Preserving the sediment from distilleries for use as a sheep and cattle food. April 10.

1889.

2110. K. Moller. Apparatus and methods adapted for breweries and distilleries for charging chambers with air free from micro-organisms and their germs, and preventing air containing the same from penetrating therein and into wort, &c. April 10.

2953. A. Seelebach. Manufacture of champagne and like wines. March 27.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—CHEMISTRY OF FOODS.

4715. J. P. Pensgood. Improvements in the preparation of tomato vinegar. March 18.

4951. E. Roberts, L. E. Roberts, and H. G. Roberts. A substitute for cream. March 20.

4961. J. Gray and T. Clement, jun. A new and improved mode and means of estimating the acidity in milk, cream, whey, and curd in the process of making butter or cheese. March 21.

5052. F. McIntyre. Improvements in the making of butter for the purpose of preserving the same. March 23.

5356. H. W. Hart. A new or improved process for manufacturing food in a concentrated cooked form. March 28.

6041. G. Dixon. Improvements in the process, apparatus, and appliances for preserving animal or vegetable products or other substances, liquids, matters, or things whatsoever. April 9.

6087. T. West. An improved process for preserving cream and the like. April 9.

6280. J. F. H. Gronwald and E. H. C. Ochluam. Improvements in the method of and apparatus for preparing milk so as to enable the same to be preserved indefinitely. Complete Specification. April 12.

B.—SANITARY CHEMISTRY.

4944. C. Johnson. An improved process for the treatment of sewage, and apparatus therefor. March 21.

5354. T. L. Seaton. Improvements connected with apparatus employed for the purification and filtration of water and other liquids. March 28.

5355. T. L. Seaton. Improved means and arrangements of articulated appliances connected with the purification and filtration of water or other liquids. March 28.

5628. B. D. Healey. Improvements in apparatus for collecting and burning noxious gases. April 2.

5753. B. Jagger, H. B. Jagger, and A. Turley. Improvements in the means employed for purifying sewage and other waters, and for deodorising and utilising the solids and excreta. April 4.

6219. W. Astrop. An improved process for deodorising, disinfecting, drying, and pulverising the solid portions of sewage. April 11.

C.—DISINFECTANTS.

5368. H. E. Kent. See Class XIII.

5984. R. Hannan. Improvements in sanitary and antiseptic preparations or compounds. April 8.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—CHEMISTRY OF FOODS.

1888.

4405. T. Adair. Manufacture of butter and cheese; flavouring, colouring and preserving same; and flavouring, colouring, and preserving rancid butter and artificial butters; and apparatus therefor. March 27.

11,180. J. Mitchell. See Class XVII.

1889.

2820. R. M. Houldsworth. A tea compound. April 3.

4391. S. Marmont. Process and means for curing or preserving all kinds of fish, flesh, and fowl, and apparatus therefor. April 17.

B.—SANITARY CHEMISTRY.

1888.

6070. G. A. J. Schott.—From C. Lortzing. Process and apparatus for purifying sewage and other liquids. April 3.

1889.

4058. H. Guthrie. Treating sewage, and construction and arrangement of means therefor. April 17.

C.—DISINFECTANTS.

1888.

17,843. W. H. Daniels. Antiseptic compound for preserving perishable articles. March 27.

1889.

3159. R. Hannan. Sanitary preparations for preventing the decomposition of sizes and similar finishes for fabrics, and for preventing the access of infectious disease. March 27.

3470. A. M. Clark.—From E. Bean. Insect-destroying compound, and method of preparing same. April 3.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

5057. E. Partington. An improvement in lining boilers or vessels used in the treatment of wood and other fibre in the manufacture of paper and other pulp. March 23.

5247. F. Weyland. Improvements in apparatus for drying card-board or paper. Complete Specification. March 27.

5418. W. L. Wise.—From J. M. Badon, Belgium. Transparent printed paper having the appearance of stained glass, and means or apparatus for its manufacture. March 29.

5643. A. J. Boulton.—From Messrs. Jung and Lindig, Germany. Improvements in or relating to the prevention of the corrosion of vessels, tubes, valves, and the like, used in the manufacture of sulphite cellulose. April 2.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

295. H. J. Medbury. Apparatus for manufacturing tubes, pipes, &c., from pulp. April 3.

333. W. H. Cook. A novel application of pulped paper stock. March 27.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

5409. J. Hancock. Improvements in the production of photographic pictures. March 29.

COMPLETE SPECIFICATION ACCEPTED.

1888.

5140. J. Hines, E. Howell, and A. Howell. Modes, means and apparatus for taking and producing photographs, and apparatus therefor. April 10.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

4812. R. H. Earle. Improvements in marine distress signal bombs. Complete Specification. March 19.

5031. P. de Montravel.—Partly communicated by O. Mauvant, Belgium. Improvements in explosives, and in the method of manufacturing the same. March 22.

5129. Sir F. A. Abel and J. Dewar. An improvement in explosives. March 25.

5208. C. R. E. Bell. Improvements in and connected with the manufacture of matches, and in machinery or apparatus therefor. March 26.

5289. H. Ritter von Dahmen and A. Strauss-Collin. A new manufacture of explosive compounds. March 27.

5503. E. Liebert. Improvements in the manufacture of explosive compounds. March 30.

5504. E. Liebert. Improvements in the manufacture of nitro-glycerin. March 30.

5644. Sir F. A. Abel and J. Dewar. An improvement in the manufacture of explosives for ammunition. Complete Specification. April 2.

5720. W. Kennish. Improved means for igniting the charge contained in explosive projectiles. Complete Specification. April 2.

6170. H. Ritter von Dahmen. Improved manufacture of explosives containing nitro-glycerin. April 10.

6185. H. T. Arbuthnot and G. Hookham. Improvements in the percussion fuses of explosive shells. April 11.

6332. W. H. Scott, L. Paris, and Scott (Limited). Improvements in connexion with electric fuses. April 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

5426. L. Plom. Blasting cartridges. April 10.

5668. M. Settle. Cartridges for blasting in mines or where inflammable gas is present. April 17.

18362. J. W. Skoglund. Manufacture of explosive compounds. April 10.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

6083. L. Mathieu and J. Morfaux. An improved process and apparatus for testing the presence of colouring matter in wines. April 9.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 5. —VOL. VIII.]

MAY 31, 1889.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.

COUNCIL FOR YEAR ENDING JULY, 1889.

President: Ludwig Mond.

Vice-Presidents:

<i>Sir I. Lowthian Bell, F.R.S.</i>	<i>David Howard.</i>
R. Forbes Carpenter.	<i>Ivan Levinstein.</i>
Prof. F. Clowes, D.Sc.	<i>E. K. Muspratt.</i>
Sir J. Neilson Cuthbertson.	<i>Dr. W. H. Perkin, F.R.S.</i>
Prof. James Dewar, F.R.S.	<i>Sir H. E. Roscoe, M.P., F.R.S.</i>
Dr. John Evans, F.R.S.	<i>Prof. W. A. Tilden, F.R.S.</i>

Ordinary Members of Council:

Alexander M. Chance.	<i>F. J. Rowan.</i>
James Duncan.	<i>Dr. Edward Schunck, F.R.S.</i>
A. E. Fletcher.	<i>E. C. C. Stanford.</i>
S. H. Johnson.	<i>J. C. Stevenson, M.P.</i>
B. E. R. Newlands.	<i>T. W. Stuart.</i>
B. S. Proctor.	<i>Thos. Tyrer.</i>

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Harter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	F. Jones, F.R.S.E.
Joseph Bernays, M.I.C.E.	Ivan Levinstein.
H. Brunner.	Prof. R. Meldola, F.R.S.
W. Lunt Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	C. O'Sullivan, F.R.S.
W. Y. Dent.	John Pattinson.
Prof. Jas. Dewar, F.R.S.	W. H. Perkin, Ph.D., F.R.S.
John Heron.	Sir H. E. Roscoe, M.P., F.R.S.

C. H. Bothamley.	G. Harris Morris, Ph.D.
E. G. Clayton.	J. M. H. Munro, D.Sc.
Julius B. Cohen, Ph.D.	H. S. Pattinson, Ph.D.
C. F. Cross.	H. T. Penternmann.
A. R. Davis.	S. G. Rawson, B.Sc.
W. W. Haldane Gee, B.Sc.	A. Roe, Ph.D.
C. Napier Hake.	F. W. Renaut.
S. Hamburger, Ph.D.	Edward Simpson.
Oswald Hamilton.	A. J. Smith, B.Sc.
John Heron.	A. Studer, Ph.D.
Bertram Hunt.	Bertram Thomas.
C. C. Hutchinson.	Eustace Thomas.
D. E. Jones, B.Sc.	V. H. Veley, M.A.
W. E. Kay.	R. Lloyd Whiteley.
A. J. King, B.Sc.	A. Wingham.

NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those Members of Council whose names are placed in italics in the annexed list, will retire from their respective offices at the forthcoming Annual General Meeting.

Sir Isaac Lowthian Bell, Bart., F.R.S., has been nominated to the office of President; and Mr. Ludwig Mond has been nominated Vice-President under Rule 11.

Dr. W. H. Perkin, F.R.S., has been nominated a Vice-President under Rule 24; Mr. James Duncan, Mr. S. H. Johnson, Dr. Hugo Müller, F.R.S., and Dr. Edward Schunck, F.R.S., have been nominated Vice-Presidents under Rule 8; and Mr. L. Archbutt, Mr. John Brock, and Mr. John Spiller have been nominated Ordinary Members of Council under Rule 17, in the place of Mr. James Duncan, Mr. S. H. Johnson, and Dr. Edward Schunck, F.R.S., nominated Vice-Presidents.

The Treasurer and Foreign Secretary have been nominated for re-election.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the Ordinary Members of Council under Rule 18. Special nomination forms for this purpose can be obtained from the General Secretary upon application.

Extract from Rule 18:—"No such nomination shall be valid, unless it be signed by at least ten members of the Society, who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's office, at least one month before the date of the commencement of the Annual General Meeting, to the election to take place at which it refers. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

ANNUAL GENERAL MEETING.

Notice is hereby given that the next Annual General Meeting will be held in London on Wednesday, Thursday, and Friday the 10th, 11th, and 12th of July next.

The following is a synopsis of the arrangements:—

Wednesday, July 10th.	
Annual Meeting, Royal Institution	- 11.0 a.m.
Doulton's Art Pottery, Lambeth	- 2.0 p.m.
Lambeth Palace	- 3.0 p.m.
Reception	- 9.0 p.m.
Thursday, July 11th.	
River Excursion, Old Swan Wharf	- 10.0 a.m.
Saccharine Works, Hammersmith	- 11.30 a.m.
Kew Gardens	- 3.0 p.m.
Dinner at "Star and Garter," Richmond	6.30 p.m.
Friday, July 12th.	
Truman, Hanbury's Brewery	- 11.0 a.m.
Cowan's Sugar Refinery, Barnes	- 11.30 a.m.
A.B.C. Sewage Works, Kingston	- 11.30 a.m.
Brush Electric Light Co., Lambeth	- 2.15 p.m.
Brin's Oxygen Co., Westminster	- 3.0 p.m.
Groth's Electric Tannery, Bermondsey	- 3.0 p.m.

Further details will be sent to each member with the Ballot List by post.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Post Office Orders in payment of subscriptions should in all instances be made payable at the General Post Office, London.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers

are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements."

LIST OF MEMBERS ELECTED. 23rd MAY, 1889.

- Alpiar, Azop, Smyrna, Asia Minor, morphia manufacturer.
 Boyd, R. Nelson, 23, Queen Anne's Gate, Westminster, S.W., civil engineer.
 Chiddey, Alf., Mt. Costizan Smelting Works, New South Wales, mine manager.
 Davis, P. H., 171, Queen Victoria Street, E.C., technical journalist.
 Groth, Lorenz A., 3, Tokenhouse Buildings, London, E.C., civil engineer.
 Latham Jno. J., 157, Albert Road, Appleton, Widnes, chemical manager.
 MacIvor, R. W. Emerson, 279A, Wick Road, South Hackney, N.E., chemist.
 Milestone, Wm. C., Garrett Lane, Wandsworth, S.W., chemical manager.
 Nicholls, Chas. P., 70, Kilby Street, Boston, Mass., U.S.A., manufacturing chemist.
 Oswood, Edw. R., Cossipore Sugar Factory, Calcutta, India, sugar refiner.
 Robinson, Graham, East Taunton, Mass., U.S.A., chemical student.
 Scott, Ernest G., c/o Lever Bros., Port Sunlight, Bebington, Cheshire, chemist.
 Turner, Hy. Blois H., 6, Lyons Range, Calcutta, India, sugar refiner.
 Wilson, Wm., Delhi, India; and c/o E. Rodger, 1, Claremont Gardens, Glasgow, merchant.

CHANGES OF ADDRESS.

C. C. Hutchinson.	

Hon. Local Sec. and Treasurer:

Thos. Tyrer, Garden Wharf, Battersea, S.W.

SESSION 1888-89.

- June 3rd.—Mr. W. P. Wynne. "Naphthalene Derivatives of Technical Importance."
 " Dr. W. S. Squire. "The Purification of Alcohol by means of Hydrocarbon Oils."
 " Messrs. Newlands Bros.' paper is postponed.
 July. — Annual General Meeting.

Meeting held Monday, March 4th, 1889.

MR. DAVID HOWARD IN THE CHAIR.

DISCUSSION ON TECHNICAL EDUCATION IN CHEMISTRY.

THE CHAIRMAN said that a vast deal had already been written and spoken on the subject of technical education, and he would not have ventured to add to that which had been laid before those interested in the subject, and thereby perhaps darken counsel by words without knowledge, but that in the last session of Parliament two Bills had been presented in the House of Commons, and would in all probability be re-introduced during the present session. Those two Bills might be taken to express the wisdom of the Legislature on the subject before them, and it was a matter of great importance that those who were interested in the question of technical education in one branch or another should express their opinions as to whether such proposals as had been made fulfilled the requirements of the trade of England in that respect. The first necessity in any such discussion was to be quite sure of agreement as to the terms used. Technical education had been much discoursed upon, but he was by no means sure that those who had spoken on the subject meant by any means the same thing. No doubt, in the two Bills he had mentioned, there was a certain agreement as to what was meant by technical education by those who proposed to legislate. But he failed to see that what was proposed in those Bills in the least agreed with what had been again and again urged upon the Society of Chemical Industry as the great need of modern chemistry. He would endeavour to make clear what he meant by that statement. There was a general consensus of opinion that technical education was a matter of great importance. But what was technical education? It had been again and again urged—and not one word of what had been said in that direction would he unsay, or do otherwise than add his humble tribute to its importance—that there was an absolute necessity for

training the heads of all chemical works to the highest extent which it was possible to attain. He used the word *head* in no narrow sense as meaning principals, but as meaning rather the *thinkers*. The thinkers in technical work could not be trained too highly: no technical education could be too high or too wide for them. Whether the English educational system fulfilled all that was required in that direction he would leave others to discuss. Whether the English system, with its endless examinations, was to be compared with the German system, which set original research far before cram, and which endeavoured to promote and foster individual thought rather than the mere absorption of other people's thoughts, it was not for him to say. He owed all his chemistry—not only what he had actually learned at the old college of chemistry, but what he had learned *how* to learn, which was a great deal more—to a German, Dr. Hofmann, and therefore he was prejudiced in favour of the German system. But when he looked at those two Bills which represented what was considered to be good for England, he failed to see anything which reminded him of his own training. It would be in the future as it had been in the past: all the members of one body would not have the same office. There must be a head, and there must be hands in any body whose organism rose above the elementary organisms that were found in physiological study. There must be those who think, and those who carry out their thoughts; there must be both head and hands; and he could not find in the Bills before him the smallest satisfaction of that need of which he had spoken—the training of the heads. Both the Bills (one bearing the names of Sir Henry Roscoe, Sir U. Kay-Shuttleworth, Sir Bernard Samuelson, Mr. G. Dixon, and Mr. Arthur Acland; and the other those of Sir William Hart Dyke, Sir Michael Hicks-Beach, and Mr. Jackson) were so completely on the one side, and all that had hitherto been said in the Society of Chemical Industry was so completely on the other, that it was highly desirable that they should make up their minds whether technical chemistry in England would be best promoted by the education of the heads or the hands, and that they should distinctly state their belief on that point before the Legislature took the matter in hand, and decided to spend vast sums of money in one way or the other. The two Bills were substantially the same in character. Both began by treating not of the education of the heads, but of the hands; in fact, both were so much on the same lines that he could not quite understand why the public money should have been spent in printing two Bills instead of one only. No doubt the initiated would tell him that there were great differences; but substantially in each case they appeared to consider that the one thing which English manufactures required, was that the workmen should be technically educated. Objection had been taken to the wording of the resolution of the Council which referred to the various Sections the discussion of this question of technical education. He would not say whether it was good English or bad; but at any rate it was the language of the Bills, and therefore, whether good or bad, it was the language of Parliament. The question they had to discuss was whether the technical education in chemistry of these Bills was what England required. As far as he knew—and his experience was that of a third of a century—the offices of the head and hands were essentially distinct. If the head did not think, the hands could not think for it. But here they had provision made only for the education of the hands. He had worked

along with workmen for many years—and in what he was saying he thought that he was but speaking the experience of others who had worked with their workmen—and though the names attached to these Bills were those of very able men, he did not see the name of any man whom he would really trust to stoke a boiler for 12 hours with the most economical consumption of fuel. Englishmen wanted to keep pace with their German friends, but he felt sure that these Bills would not enable them to do so. He saw no evidence that German chemical education was confined to the workmen; he would have said rather that it was confined to the leaders of the workmen. The German workman, however, had one kind of training which was denied to ours—which he hardly dared venture to touch upon before an English audience. He had three years' training in the finest school of intelligent obedience which it was possible to find—the German military service. It might be that Englishmen could do as well as the Germans; but at any rate we should first make quite certain as to whether the secret of the latter's success did not lie in their military service. One did not find that the English lad of 18 was taught those lessons which the German lad of 18 was taught, and which were not commonly called technical education. The German lad was taught military service. They might ask, what had that to do with chemistry; to which he would reply, that intelligent obedience was the foundation of all successful manufacture. He said *intelligent* obedience, for no one valued intelligence in a workman more than he did. An intelligent master needed an intelligent workman; but he did most earnestly deprecate the idea that that intelligence should be narrowed down to one particular groove in which the man was to work. He had had some experience of workmen, and the best chemists he had found among them had not been those who had been trained solely in chemical factories, but those who had had experience in widely different spheres. It might be paradoxical, but it was not wholly unwise to say that if he were training a workman, he would rather train him first in something else than the particular sphere which he was to occupy eventually. The great thing needful was that power of adaptation of the mind from one sphere to another which required that a man should not be taught all his days merely the one thing which he is to do when grown up. Looking at the Bills to which he had referred, he found that the definitions given in the Government Bills were as follows:—"The expression 'technical instruction' means instruction in the principles of science and art applicable to industries, and in the application of special branches of science and art to specific industries or employments. It does not include teaching the practice of any trade or industry or employment, but, subject as aforesaid, includes instruction in the branches of science and art with respect to which grants are for the time being made by the Department of Science and Art, and any other form of instruction which may for the time being be sanctioned by that Department." Was that technical instruction? Did we require, in order to enable English factories to surpass the German factories, that our workmen should understand the principles of science and art, and that their leaders should not? He said no. What was wanted was intelligent obedience, and not workmen who should teach their leaders science. When the workman had attained a certain position in the factory, nothing could be better than that he should be taught, as far as he had ability to learn, the principles on which he was working. But practice came before

theory in successful work. He could imagine nothing more beneficial than the action of the City of London in providing technical education for those who knew what they are about, and had had the mere manual instruction; but he questioned whether the teaching of theoretical chemistry to boys in Board schools would be of the slightest use to chemical factories. He had tried it. He could manage any boy who had not been taught chemistry; but one who had, he confessed, was beyond him. Undoubtedly an improvement in the elementary instruction of English boys was much wanted. Many years' experience as chairman of a School Board, and generally in the supervision of elementary education, had taught him that. What was required was more practical knowledge, more application of instruction to the wants of daily life, and less to a faint shadow of scholastic training and literary education for the working classes. But the proposed Bills gave nothing of that. They proposed that after a boy had passed through those deep mysteries called the "standards," he should be submitted to scientific training. He had nothing to say against science; but it appeared to him to be a mere delusion to suppose that English chemistry could be raised to a German level by calling upon the workmen to attend lectures. The heads and thinkers should be highly trained; all they asked for in their workmen was intelligence. If the leaders could not teach the workmen, it was an ill day for English manufacturing chemistry. Turning again to the Bills, he found that the science subjects spoken of were "The use of ordinary tools, commercial arithmetic, commercial geography, book-keeping, shorthand, French, German, and other modern languages, free-hand and machine drawing, and any other subject which the Education Department and the Science and Art Department jointly may from time to time prescribe as being a proper subject of technical education for the purposes of commerce, agriculture, or any trade or handicraft." With regard to the use of tools, he was quite content to leave to the consideration of the skilled workmen of England the question whether their handicrafts should be taught in the public schools. They were the best judges as to whether a boy of 14 could be taught the use of ordinary tools in an elementary school. For his part, he thought the boy would be much better taught in a workshop. But with regard to the other matters, the question was whether public money ought to be used for those purposes, or whether it should not rather be employed for the better endowment of scientific teaching and research in the higher schools. (Applause.) He had worked among workmen for so many years that he was not prejudiced against them, nor did he grudge them anything they could get. But if the lessons learnt from the study of biology were regarded, they would find that the highest organisms were those in which the different functions of the body were most differentiated; that the highest types were those in which the brain thought, and the hands carried out its thoughts. It was only in the lower organisms that each member acted for itself; where if the head were cut off the body went on quite comfortably without it, as in the case of certain insects. Were we to imitate the lower organisms in our workshops, and trust to the theoretical education of every workman, or were we to follow that differentiation which nature taught us through the science of biology? He had insisted on this point because it was evident that the idea in the minds of the promoters of these Bills, and expressive of the mind of the Legislature, was that what was required was to train the workman

in theory and not in practice. He believed, however, that what was wanted was to train the workman in intelligent obedience, and the thinkers or heads in the highest manner possible. Unless we did this, we could not hope to equal our German friends. If one examined the organisation of a German factory one found at the head of it men of the highest scientific training, while the hands were men whose chief training had been that of the German military service.

Mr. T. TYRER said it was a subject for regret that the wording of the question submitted for discussion by the Sections was defective in two respects:—

First, it was by its limited terms almost an invitation to go outside its terms in any adequate discussion.

Second, the term technical was in his opinion misplaced. The question should read thus: "*In what direction is State aid needed to assist education in technical chemistry?*"

Now it so happened that he himself was the author of the original scheme for discussion, the terms of which were as follows:—

What is technical education from a chemical point of view?

How should it be given?

- a. Elementary schools.
- b. Continuation schools.
- c. Evening schools.
- d. Technical or polytechnic schools.
- e. Existing institutions.

Ways and means:—

- a. State aid.
 1. Money or building.
 2. Endowments.
- b. Voluntary aid.
 1. Pure.
 2. Rates (local).

The Council reduced this to one point for the sake of keeping discussions within limits, viz.:—"In what direction is State aid needed to assist technical education in chemistry?" and ordered copies of the two Technical Education Bills of 1888 to be sent to each Chairman.

He (Mr. Tyrer) proposed to utilise his original scheme in his remarks, and would first indicate what technical chemistry was. It would scarcely be disputed that it was *applied* chemistry. If so, then chemistry, or chemical science, purely and simply, was not technical. Neither was that combination of applied chemistry and engineering called chemical technology. He would grant the existence of the most intimate correlation between pure chemistry applied or technical chemistry and chemical engineering, and would say that only a man possessing extensive knowledge of the whole three could be said to be the ideal technologist or manufacturer.

Perhaps he might be allowed to define the position by an illustration. The scientific institutions of the country possessed many professors of chemistry; how many were teachers of any other than pure chemistry? In how many institutions were there professors of technical or applied chemistry, or, if there were, how many were really, or indeed could be, technologists in the chemical sense of the term? He made no reflection upon these gentlemen, who needed only the clear demand to very speedily discover a means of supplying it. No one would argue for the identity of pure chemistry with technical chemistry, and it should be remembered that technical chemistry consisted in the application of pure chemistry to processes of manufacture. No operations on the laboratory scale were similar in every respect

to those in the works, and the knowledge of first principles was necessary in order to overcome the difficulties and obstacles to successful results in manufactures.

Granting his assumption that technical chemistry meant applied chemistry, was not the next question how it should be given in elementary schools? Emphatically not; the object of these was to impart the elements of education, and that perfectly; though what was attempted under the existing Code was neither the best in method nor the most adequate for its purpose. Here all that could be done was to instil the rudiments of general knowledge thoroughly, with such a proportion of teaching in science, by simple demonstration and experiment where practicable, as would excite juvenile interest and prepare the way for development at a later period, namely, in the continuation schools, where more complete scientific instruction should be given. In these, supported probably, as now, by grants from the Imperial funds and local rates, capable children should be allowed to gain specific knowledge. These State-aided schools would speedily become the secondary schools of the nation. Provision should be made for the use of these schools in the evening by voluntary students and artisans of limited means and scanty leisure.

In addition, and also aided from the Imperial funds in great measure, there should be purely technical schools or colleges, and the teachers or professors in every branch of science should be specialised, that is, there should be a teacher and professor of theoretical science, and another of its application; in the case of chemistry there should be a professor of pure chemistry, and a professor of applied or technical chemistry.

Now, as regarded existing institutions, many were most admirably situated; most were very fairly adapted to the purposes for which they were established, and a few were especially suitable. They were manned by highly qualified professors of pure science, but only in few instances, so far as he knew, were there professors of applied chemistry.

Were these institutions utilised to the best advantage, that is for technical purposes? No! and in many cases they could not be. If he knew anything of the requirements of a laboratory for the study of technical chemistry, and he thought he did, there were few places suitable; and certainly the use of the same laboratory, where research and purely scientific work was pursued, for the purposes of technical research or teaching would be an absurdity. It came, therefore, to this, that (1) there must be separate technical laboratories and teaching appliances in every institution for teaching science; (2) the smaller and more special institutions suited for the neighbourhoods of manufacturing centres must be increased; (3) State and elementary school rooms and premises for the teaching of elementary science should be made available.

Now came the question of ways and means. In this country, judging from the past, there was no hope that the requisite assistance would be obtained from the Imperial Exchequer; but it would be generally agreed that the State ought to contribute very much more than it now did to the promotion of education in science. In this country a combination of State aid by means of grants in aid, &c., contributions from local taxation or rates, supplemented by voluntary contributions, chiefly in form of buildings or scholarships, prevailed. This combination was likely to continue, but most would agree that (1) buildings should be provided in the main, as now, by local authorities and interests, supple-

mented by the State in a certain definite proportion. (2) Chairs should be endowed by the State on some equitable principle as to distribution, and the professors be made, in fact, servants of the State with a right to its honours and pensions. (3) Working expenses should be controlled by a representative local board, subject to appeal to the higher authority; the teaching to have an adequate representation upon this board. They should be covered by—

1. Fees from students.
2. Rate in aid from the locality.

He could not conclude without endorsing the opinion that the defect in our English system of education lay in the absence of any true secondary education, and until this want was supplied they would fail to progress. Also that it was not the workman, as such, who needed that technical education which is to restore our equality, much less supremacy, in technology. If he was sober, obedient, and industrious, elementary education would make him as efficient as his foreign rival probably simply as a workman. It had been stated that German professors and teachers were constantly in contact with manufacturers and works, and were continually referred to and consulted on the application of pure science to technical operations. If so, it behoved our professors and teachers to cultivate in their own interests the most cordial relations with technologists.

Dr. J. H. GLADSTONE said that this was a subject upon which he had thought and spoken a good deal. He could only approach it in certain directions, and he hoped that anything he might say would be accepted as an elementary contribution to the discussion of a large and important question. In the first place it was desirable to know exactly what was meant by technical education. No doubt the phrase had caught the attention of the public very much during recent years. He and a few others were calling for it and preaching it many years ago, but they found themselves as voices in the wilderness, with no one to listen. Now everybody seemed to have awakened to the importance of the subject, and there was a general chorus of voices clamouring for it. But technical education meant different things to different people. With some it meant giving such instruction in the theoretical or practical part of a profession as would fit a person for carrying out his business in life. That was his view of the correct meaning of the term. Thus the technical education of a medical man was given in hospitals, that of a lawyer or clergyman in their proper schools or colleges, and that of a workman to a large extent in the workshop. This specialised instruction was the more correct meaning of the term technical education. There was another matter of great importance which generally went by the same name, but which required a different term to distinguish it, namely, the fitting a man, so far as his bodily senses were concerned, for the business which he might have to do in after life. He agreed with the Chairman in what he had asserted, but not in what he had denied. He agreed heart and soul with what he had said about the necessity for educating the heads of establishments. The largest possible amount of theoretical and practical knowledge was wanted in the leaders of industry, and the more their minds were cultivated the better their work would be. The example of Germany was well quoted in that respect. How far the State should be called upon to supply that education, or to subsidise it, was another matter. There were establishments in existence, and others

could be created, which gave this kind of education, but he was not quite sure that John Bull was prepared to put his hand in his pocket to help the sons of men of substance to gain such education—to teach the capitalist, in fact. Then there were what had been called the “hands,” though of course the one class merged gradually into the other. It appeared to him that there was something deficient in our present arrangements with regard to the education of workmen. That education used to be given by the masters in their small workshops, but lately, owing to the general subdivision of labour, the practice was dying out, and there arose the danger that a man should be taught simply to perform one little part of his art or industry, becoming very perfect in that particular line. So long as the trade flowed on in the same channel, that practice might work well, though of course the man had little chance of rising. But if a change took place, or the man's particular work was done by machinery, then he was utterly superseded and drifted away into the great ocean of the unemployed. What was wanted was that men should be educated to a certain extent in the general principles of the art they pursued, so that they could turn from one part to another and employ some intelligence in their work, and not do it by rule of thumb or simply by following the direction of their “heads.” He agreed with much that Mr. Tyrer had said as to how that want should be supplied. Of the two Bills quoted he preferred that proposed by Sir Henry Rosecoe, but he hoped that in the present session some proposals would be made which would be more acceptable generally than those now before them. The nation was, he thought, prepared to give some support to “continuation schools,” as suggested by Mr. Tyrer. Such schools had risen up in various places, and were subsidised by public bodies, and he believed that the Government would be willing also to subsidise some good system of polytechnic schools. If such a course were adopted, he hoped that those who would go to the schools would be those who had already made preparation to a certain extent for the business they were to follow; for technical classes would be of little value to workmen unless they had had an education better than that ordinarily given in the elementary schools. The education given in these State-aided schools was too ambitious on the literary side. The old idea of education, which was perhaps very good in the middle ages, was certainly not fitted for the 19th century or for the working classes. It was a mistake to attempt to give high literary culture to children in elementary schools. At any rate, concurrently with the teaching of words, there should be the teaching of things; but the teaching of things should come first, then the words and phrases by which things are expressed. That was the system followed to a large extent in infant schools; and it was really a better and truer education than was given in boys' schools, because the infants were taught to use their faculties and made fit for imbibing knowledge afterwards. But in boys' and girls' elementary schools things were very different, and still more so in middle-class schools. The natural activity of the children was crushed down; they were taught that it was naughty to ask questions, and that they should sit still. What he wanted to see was a system of education which should exercise the child's every faculty, draw out all his curiosity, and satisfy it by object lessons, science lessons, and lessons which should make him acquainted with the world, while his fingers should be trained in manual exercises. Such a system should be begun in the infant schools and be followed without intermission into the highest standards. He did not think that

they should be taught any particular science (except perhaps a little practical chemistry), but rather the principles of all science—those great facts and truths which underlie chemistry and physics, mechanics, geology, mineralogy, and every other science. They should also be taught something of the use of tools. In fact the education should be such that every child would gain some advantage from it, whatever might be his pursuit afterwards. It would not be fair to teach a class one particular art or science. The instruction should be such as would bring out the intelligence of every boy and enable him to turn easily to any work, light or heavy, which he might have to do in after life. There was a tendency in this direction at the present time, and such discussions as they were engaged in would certainly advance it.

Mr. C. F. Cross said that, referring to the scheme set forth by Mr. Tyrer, he was disposed to answer the questions put to the meeting in the negative. He thought that as chemists they should not ask the Government for any aid. Firstly, because State aid administered by the State was rarely satisfactory; and, secondly, because they had sufficient educational power in the institutions which already existed. Thirdly, there appeared to be very little demand on the part of manufacturers for such education of the higher kind as already existed. There were many young chemists in England who had been at great pains to make themselves masters of chemical method; yet manufacturers generally did not recognise the necessity for research, and certainly had not risen to the height of the views expressed by the Chairman as to what should be required from the chemists they employed. One had only to peruse the technical journals from time to time to see the poor character of the men who were advertised for by the chemical manufacturers of this country; and having seen that, one ceased to wonder at the paucity of the demand for men of calibre and research. He would refer to two of Mr. Tyrer's selections of existing institutions for higher education in chemistry. Polytechnic schools were already in existence, and he saw several representatives of them present who would testify that they had done good work. With regard to such institutions as King's College and Owens College, in which he had studied, he thought them founded on altogether inelastic lines. They were by their very constitution incapable of taking full advantage of the results which they themselves achieved. They produced men who went to Germany and elsewhere for higher education and returned enriched with experience. If these institutions were founded on the same lines as the German institutions there would be a means for the country to avail itself of the educated power which those students possessed. Such men would be glad to give courses of lectures in connexion with the institution, or to ask for a room in which to prosecute research. Let the colleges aim at becoming centres of intelligence, let the student have the countenance of his *almater*, and let him do his work there so long as he continued to devote himself to research. No harm could be done, and a great deal of working power would be utilised in a practical way. He would conclude by saying that he thought their answer to the first question should be in the negative; and with regard to the second, that existing institutions were quite capable of fulfilling all the demands made upon our chemists by our manufacturing industries.

Mr. JAMES MACTEAR said that the subject under discussion had excited much interest in Glasgow

some 10 years ago. One of the results of the attention it then received was the establishment, by the late Mr. James Young, of a Chair of Technical Chemistry in the Andersonian Institute. He (Mr. Mactear) was one of the trustees, and as such was acquainted with its working, and he had no hesitation in saying that while, as a chair of chemistry, it had been of immense value to the country, as a chair of *technical* chemistry it had been an absolute failure. It had had the effect of splitting up the teaching of chemistry in that institution into two, a chair of pure chemistry and a chair of applied chemistry; but he would defy anyone to say wherein the difference lay. No one could be more capable than Professor Mills, who occupied the chair, but he doubted whether he had turned out in any direction more successful students than were turned out by Penney, Thorpe, Tatlock, Dittmar, or the late Dr. Wallace—men who professed only to teach chemistry, but in its application to the wants of everyday life. A great deal had been said and written about the necessity for new centres for teaching technical chemistry, but he thought such centres had been amply provided where needed. What was required now was to awaken in the minds of workmen who wished to better their position a desire to learn. Those who had such a desire would find ample opportunities of gratifying it; and he thought the best way of doing so would be by attending evening classes. Teaching technical chemistry to a lad who was to become a working man was more or less a farce. His time at school was too short to permit him to drink in the proper laws of theoretical work; and to give him a mere smattering of chemistry, physics, and mechanics would only confuse him and afford him no knowledge of real work. The great obstacle to the improvement of English workmen was the existence of an enormous mass of trades-unionism. Trades-unionism had laid a heavy hand upon the British workman. It had done much for him in many ways; but in most trades the result was to keep the men down to a dead level—the man who desired to rise being regarded as an enemy to his class. It was not so in Germany; it was so in France, even more than in England. So that to obtain a foreman in France from the working classes was very difficult. The moment such a man became a foreman, every man's hand was against him, and he was practically boycotted by the workmen; and the same sort of feeling unfortunately existed in England. Was it possible, he asked, by any amount of State aid, to teach a man—a glass-blower, for example—his trade by technical education, when the Glass Blowers' Union would not, in all probability, allow him to enter the trade at all, the admission of apprentices being most strictly limited; or to teach a man technical engineering, if he could not enter the engineering ranks because of his union? That was a difficulty which had to be faced, and which no amount of technical education had been able to overcome in Scotland, where they had mechanics' institutes and evening classes with what might be called extra-mural professors. In England there was ample power for giving the technical education that was wanted by polytechnic institutions, and trade schools. The fault lay in the fact that there was not a demand for that education. It seemed to him, therefore, that instead of asking for more money to erect new centres of education they should din into the ears of the working man that if he wished to improve his knowledge and position it was for him to take advantage of the opportunities already provided, and not that more opportunities should be provided. He knew of only

one case of a developed system of technical training, and that was in connexion with the weaving and dyeing schools; but in that case they had no trades-union to deal with. He had carefully studied the system of technical education pursued in Boston and Philadelphia, and had found that as a means of teaching mechanical work it had great advantages. Lads who had gone through a course of three years' training went out into the world and readily secured positions as under foremen, rising afterwards to be foremen or managers. Still the demand for technical education even there was by no means what it should be. The Chairman had made a great point of military training, and he fully agreed with him in that. He had had 25 years' experience of workmen—volunteers and non-volunteers—and he had found that the volunteers acquired during their few years in the ranks an amenability to discipline which the others had not. Such a man knew that in order to be able to command himself he must be able to obey. But an ordinary lad nowadays seemed neither willing to learn nor to obey. His chief object seemed to be to get into a corner and evade doing his proper work.

Mr. F. J. LLOYD, after a few sentences vindicating King's College against Mr. Cross's remarks, said that the subject as put before the meeting assumed that State aid was needed, and the only question they had to discuss was how that aid could be best given. He regretted that that point had not been kept to more closely by previous speakers. They might talk as much as they liked, but Parliament had to act; and the only good they could hope to do was, if necessary, to show Parliament that they were not acting in the right way. In the first place, they should separate from this question the question of original research and its endowment. The feeling of the meeting seemed to be that any workman could be trained to do work intelligently if one only obtained obedience. He had been much surprised at the Chairman's remark that military training gave intelligent obedience. It gave no intelligence whatever, but it gave mechanical obedience. We had not that military training in England, and we were a race that objected to obedience. To a certain extent it was the absence of primary education in the past and the want of that primary education in the workmen of the present day that caused workmen to be so unamenable to rules and regulations laid down by their masters; but he believed that the primary education now and for some time past given in England would produce a different class of men in the future, men who would be obedient, intelligently and not mechanically. He quite agreed with Parliament that more than mere obedience was wanted, whereas all that the Chairman seemed to think necessary was obedience.

The CHAIRMAN: I said intelligent obedience.

Mr. LLOYD, continuing, admitted that the Chairman had said so; but the question was what did he mean by intelligent obedience. If he set a laboratory assistant to watch a certain operation, and then, being himself otherwise occupied and forgetting the said operation, a time arrived when something should be done, he would consider that the man would show his intelligence by stopping the operation, and the want of intelligence by his quietly and obediently watching it spoil. He had known that to happen; and it must be so wherever technical work was carried on. The question was what education could the Government give. He thought it wrong that Government should educate those who could afford to educate themselves. What was

wanted was that after a man had entered a trade and had shown that he possessed the mental capacity for benefiting by technical education, he should be put in a position to receive it at the cost of the State. Amongst a hundred workmen who might be excellent as mere tools there would be only a few capable of receiving the instruction mentioned in the Bill as indicating the views of the Government. The aim of the Bill was that men who had attained a certain proficiency in their work, and who desired to obtain in addition to their technical skill a knowledge of the principles on which their industry is based, should have an opportunity of obtaining that knowledge at the cost of the State. If in the opinion of the members present the Bills did not give such men that opportunity, it was for them to say by what means it could be given. But he hoped that they would not merely pull the Bill to pieces and put nothing in its place, as was so often done.

The CHAIRMAN said, that in fairness to himself he must read the conditions laid down in the Bill for receiving technical education. He had not a word to say against educating the intelligent foreman; but the provisions of the Bill related simply to "anyone who can read a passage from some standard author, who can write a short theme or letter on an easy subject," whose "spelling, handwriting, and composition" are considered satisfactory, "an exercise in dictation" being, "at the discretion of the inspector, substituted for composition"; and who, in arithmetic can do "fractions, vulgar and decimal, simple proportion, and simple interest."

Mr. W. LASCELLES-SCOTT, speaking as a chemical manager of over a quarter of a century's experience, considered that the tendency of modern chemical education had been in the wrong direction. He hoped that a lesson would be taken from what was now going on in Germany and America, and that a workman's chemical education would in future commence at the practical rather than the theoretical side. He would, for example, begin by teaching a man how to stir a mass in a pot without doing any damage, and then, but not *till* then, would teach him the theoretical considerations upon which his work was based. He agreed that it would be of great advantage to England to have State aid given, both directly and indirectly, for the development of technical education, provided that aid was applied in the right way. The present time was, in his opinion, peculiarly suitable for the discussion of this question, because the newly constituted County Councils were about to commence their official work, and this was a field in which they could be of immense practical use. It seemed to him that previous speakers had not paid sufficient attention to the geographical aspect of the question before them. In one district workmen would require to be educated in quite a different direction to that of another district, and in his opinion, therefore, no system of education and no Parliamentary Bill on the subject would be satisfactory unless it was administered by the body best able to judge of the needs of any particular district, namely, the County Council of that district. And further, it was desirable that State aid should be applied to practical work, and not to the theoretical or academical portion of a man's education. This latter, with the exception, of course, of the very earliest or rudimentary stages, might safely be left to be covered by private scholastic establishments. Another phase of the question which required further consideration was that relating to appren-

ticeship. There were symptoms in some directions, he was pleased to observe, of a return to the old plan of apprenticeships; and in his opinion no system of education for converting raw lads into skilled workmen would be successful, unless its secondary or final courses were supplemented by a system of apprenticeships. It was in this direction that State aid might well be applied, under the direct supervision of the County Councils. It had been said that there were difficulties in the way—that the factories and workshops were closed against these raw hands. But that was only a difficulty of to-day, and was already showing signs of passing away. He had made inquiries on the subject in various places, and large manufacturers and companies had told him that they were willing to admit workmen and youths, provided they were guarded in some degree against loss by having the benefit of their (the workmen's) services secured to them for some time. He certainly thought that these points should be included in any Bill which might be brought forward, and in any case he would be strongly opposed to the perpetuation of the present vicious, "South Kensington" mode of education, and hoped for something better and more practically useful than Sir H. Roseoe's Bill of the previous session.

Mr. R. J. FRISWELL thought that the first thing needful was to teach the English nation to respect science and art. Another necessity was that the upper classes in this country should, as did the upper classes in Germany, set an example of plain living and high thinking. Under the present conditions directly a man began to make money, whether by a chemical works or other means, he wanted to move up into a higher class of society, and so there was a constant drafting from the ranks of those who should be the intelligent leaders among manufacturers. In Germany they had rigid class distinctions, and a chemical manufacturer was proud of becoming a good chemist and not of being a second-rate county magnate. In the same way the workman did not aspire to step into the class above his, but was content to be a thoroughly good workman. Much had been said about the best way of carrying out technical education, but it seemed to him that the first thing to be done was to instil these fundamentals into the nation, and then they might consider the other matters. Mr. Lloyd had taken the Chairman to task for attributing German success partly to military training, and had denied that such training would be productive of intelligent obedience. If Mr. Lloyd had had more experience of chemical works than he apparently had he would hardly have made that assertion. For before a man became a fit subject for military obedience in the usual sense of the term, he had to undergo an elaborate course of what was truly technical education. His own experience of chemical works made him entirely agree with the Chairman's remarks. The greatest nuisance in a chemical factory was the man who presumed to think for himself and to raise questions as to the principles of the processes he was instructed to carry out. The technical education which a workman required concerned only a few simple operations, best taught by fellow workers in a factory. He preferred the man who would look out for the things he was told to look out for, and do what he was told to do. As an instance of the results of a man thinking for himself rather than obeying orders, he might mention that in the laboratory in which he was engaged they often had tarry substances to clean off the apparatus, some of them being soluble in sulphuric acid and others in

caustic soda, and the laboratory man was of course instructed to treat them accordingly. One day he showed his power of thinking for himself by combining the two substances, and announced that he had discovered a mixture which would be invaluable, because it would clean anything, as it combined the properties of vitriol and caustic soda. That was not the sort of thing he desired to extend. What he wished to see was that the men whose capital made them masters of chemical factories should respect the scientific worker, and not expect to take a boy from a board school, call him a "chemist," and pay him 30 shillings a week. Such as they were not the sort of men to make England maintain its lead in manufactures. If leaders of industry would respect science, this country had abundant means of supplying it, and if not this, then the great continental schools. Englishmen were never slack to go to other countries to obtain what they wanted, whether sugar or brains. They had had sufficient intelligence in the past to import Hans Holbein and Van Dyck, and an immense army of foreign art workers, and they could now if they chose get chemical brains either from the schools of this country or from the continent. It was not a case of insufficient technical education, but of an insufficient demand for its possessors on the part of those who, though they ignored it, were nevertheless absolutely dependent on chemical science for the creation and continuation of the industries by which they lived.

Dr. H. E. ARMSTRONG said that he presumed the object of the meeting was to criticise the Bills presented to Parliament last session, with a view to guiding any future legislation; but that object appeared to have been largely lost sight of by the previous speakers. He could not help thinking that the Chairman, in his opening remarks, had been not altogether just to those who had backed these Bills, especially to Sir Henry Roseoe. It should be borne in mind that the gentlemen in question were practical men, possessing a fair knowledge of the present state of education in the country, and having a fair appreciation, not only of what was needed, but of the way in which legislation was conducted in England. He thought, therefore, that they deserved somewhat more credit than the Chairman was disposed to give them. They deserved credit for availing themselves of the term "technical education," because they knew it to be a popular expression. If asked to define that expression, they would probably agree that it was difficult or impossible to do so, and that the great safeguard against harm coming from its use was the fact that no two people agreed as to its definition. That was the only justification for the use of the word in the way it was so frequently used at present. Though not expressed or implied in the Bill, and though he had no authority to interpret the views of the framers, he thought that what they had in their minds was very much what had been indicated by Dr. Gladstone in his remarks, and that what they desired to do was to give a wider system of State education, with greater latitude to those who carried it out, so that they might teach something more than the "three R's," and go beyond that literary training which was at present in vogue. That, he thought, must really be their object; and, however much the meeting might object to minor details, if the Bill produced that effect, they ought to do what they could to support it. The outcome of any such measure had very little to do with what was stated in the Bill. The success which would attend the passing of the measure must depend on the way in which it was interpreted by the teachers; and if teaching of the kind suggested

was to be of any value to the country, it must be because proper views of what were rational methods of teaching prevailed throughout the schools. Sooner or later, one result of passing such a Bill must be the appointment of a skilled staff of inspectors. At present the inspectors were all literary men, having neither a knowledge of science nor the faintest appreciation of its merits. If the present system of appointing inspectors should become modified by the introduction of a Bill, such as that before them, it would be a result of great value. He agreed with the Chairman that the condition of the chemical manufactures of the country would not be materially altered by giving our workmen technical education; yet by rendering them more obedient we should gain a great deal; and better teaching would no doubt beget habits of obedience. For his part, he hoped that the military system, except in the form of volunteering, would never prevail. He had had considerable personal experience of German chemical works, and had seen that the habits of obedience referred to by the Chairman were of much value. Yet, while recognising that value, he thought that there was much truth in Mr. Lloyd's remark that we were not an obedient nation—and he hoped we never should be. He could not help noticing that the German was becoming more and more blindly obedient year by year, and it struck him forcibly that original thought was being more or less crushed out of the nation in consequence. In England, original thought was largely the outcome of the inherent disobedience—or rather, reasoning obedience—of the people: of the natural tendency of the Englishman always to say "Why should I?" when told to do a thing, and yet to do it sooner or later. The position he took up was that if the Society could suggest any minor improvements to the promoters of the Bill, let it do so. But with regard to the question: "In what direction is State aid needed to assist technical education in chemistry?" the proper course had been indicated by Mr. Friswell, and by the Chairman in his first words. Chemical manufacturers should be made to appreciate the value of chemistry. If the Government could compel every chemical manufacturer to come forward and make a confession of faith, such as the Chairman had made, the problem would be solved. A certain amount of aid was needed, especially in the provincial colleges, and the Government had announced their intention of giving help; but what was most needed was aid from the manufacturers. He wanted to see students sent to the colleges. Although willing to do all he could to help in this matter, he always felt that at present he was in a more or less powerless condition, not only on account of the number, but especially of the quality of the students of chemistry. Most students of chemistry were not of a high grade. Chemical science had not a high reputation, and the consequence was that the better class of men took other subjects—the bar, medicine, and others—which offered better opportunities. At present, therefore, chemical science did not command a fair proportion of the talent of the country, and until it got that proportion little good would be done. Teachers must, too, have the students under their control for a longer time. At present it was difficult to persuade parents to allow their sons to stay three years at college, and at most colleges only half that time was devoted to chemistry. Teachers were not only expected to turn out a lad with a fair knowledge of the principles of chemistry, but also to make him an expert workman; and the result was what might be expected, either he was turned out a fairly efficient workman without any proper knowledge of

his subject, or else with a good understanding of his subject and a very slight proficiency on the analytical side. People seemed to understand that it was impossible to make a man a good engineer on the theoretical side as well as a competent workman in so short a time. An engineering pupil had to spend a number of years at college to learn the science of his profession, and then he spent three or four years at a works in acquiring mechanical proficiency. Until chemical students underwent a similar course of training very little progress would be made. It was that which had made the Germans what they are. If one went into a German works of the better class, one found lots of men who had been at the universities for five, six, seven, or even eight years. That was the type of man sought for in Germany at present, and not the man who had been to a technical school and learnt a little bit of his subject, *i.e.*, some special branch of technical chemistry. He thought that Mr. Tyrer had made a mistake with reference to that point, because, after all, there was no good in attempting to define the difference between a technical chemist and a pure chemist. What was wanted was to turn out men who knew their subject, and who were competent independent workers.

Dr. DOBBIE said it was doubtless known to the meeting that Government had already made a small experiment in the endowment of technical education. He referred to the vote of 5,000*l.* taken last year in aid of agricultural education. The college with which he was connected had ever since its foundation taken an active part in the promotion of agricultural education, and had, therefore, been entrusted with the application of a portion of the grant. The principle adopted by the Privy Council was to make awards only to such institutions as had done useful work in the way of agricultural education. Bangor College, therefore, had to prove that it had already done good work in that direction, and then it was allowed a small share of the grant, 200*l.* The college authorities now aimed at providing a system of agricultural education for the whole of North Wales. In the college itself they attempted to give a thorough education suitable for the sons of wealthy farmers who could attend college for two or three years. Their chief work, however, lay in the agricultural districts. In every such district of North Wales they had established centres of agricultural education; they gave lectures to classes of farmers, and illustrated them by experiments in the field; they had started no less than three dairy schools in different parts of the principality. They did not attempt to teach the farmer how to drive a plough; but they taught him the scientific principles on which he manured and tilled his ground and fed his cattle. As soon as the farmers understood what they aimed at it was not only possible to get large and intelligent classes together, but the demand for such classes was greater than they could meet. They had given four courses this year, and the average attendance had been from 80 to 100. Those who attended were not schoolboys, but men actually engaged in the practical operations of farming. Many of them farmed a large number of acres and had under their control a large body of workmen. They were thus, in the words of the chairman, educating the "heads": those who corresponded to the foremen and masters of our factories and chemical works. They could do nothing for the labourers; they confined themselves to teaching the farmer the scientific basis of his craft. In the dairy schools they were obliged to attempt something more than this. They had in the first place to teach the dairymaids and men something about the

composition of milk, and about the conditions under which butter and cheese of the best quality and in the largest quantity could be obtained from it. But they had found it necessary to go further in this case and give instructions in the actual manipulation of the milk. This was due to the backward state of the dairy industry in the principality. In Denmark, where the dairy industry had been brought to a higher pitch of perfection than in any other country in the world, they had in addition to numerous and excellent dairy schools a system of apprenticeship under which many dairymaids received their training; and no doubt when the industry had been generally improved in this country that method of training would be largely resorted to. For the present it was necessary to teach the practice as well as the theory in their schools. These remarks had a direct bearing on the question under discussion, that question being as to the direction in which technical education could best be assisted by the State. In the case of the University College of North Wales at Bangor, the money was given by the Privy Council without any restrictions as to its disposal. The Council had satisfied itself that the college could make good use of it, and knew best what were the needs of the particular district in which it was situated. The grant was not perpetual, its continuance being dependent on proof of good work being done. In giving the money to an existing institution possessing nearly all the appliances and staff for giving technical education the Council had, he thought, acted wisely. It had saved the great expense of erecting new laboratories and founding new chairs. He could not help thinking that the question of State aid to technical education might be treated with advantage in a similar manner throughout the whole of England. If the Government, instead of creating a vast new system of technical education were to subsidise the provincial colleges, and leave them to conduct the work of technical education in the way best suited for the district in which they were situated, he thought that would be a satisfactory solution of the question.

Professor THORPE said that Dr. Armstrong having referred to the gentlemen who had backed Sir Henry Roscoe's Bill, it ought in common fairness to be stated that so far as training and experience went Mr. Lawes Jackson, whose name was on the back of the Government Bill, should be scarcely less competent to deal with such a question. Mr. Jackson in former days played a prominent part in educational matters in the town for which he was one of the members, and he was still at the head of a large manufacturing establishment there, which had very close relationships with applied chemistry. With respect to Mr. Mactear's remarks, he must compliment him on the easy way in which time was apparently dealing with him, for it was nearly twice the 10 years stated by Mr. Mactear since the Technical College of Chemistry in Glasgow was created. In virtue of his former connexion with Anderson's College, he had had some little experience of the working of the Young chair, and it was perfectly true that, up to the present, it had hardly realised the anticipations of its founder and his friend. He was well aware of the motives of the late Dr. James Young in creating the chair; and probably no man was better qualified to form an opinion as to the kind of training which a workman needed for success in chemical manufactures. Mr. Young was practically the founder of a new industry, and in its development he had no traditions to guide him; he had to create practically everything connected with it, and much of his success was undoubtedly due to the character of the train-

ing which he had himself received under Graham. With respect to the Young chair, some of its ill-success must be set down to the want of appreciation of such places. Although the Technical College was situated in the heart of the chemical industry of the West of Scotland, the manufacturers round about had hitherto been singularly slow for some reason or other in taking advantage of the opportunities offered to them by its founder. It was to be hoped, however, that under the recent reorganisation of the place better results would speedily follow. Much had been said about the uses of military discipline as inculcating that spirit of obedience which the heads of great manufacturing establishments desire to see. No doubt military obedience could be cultivated, but whether that was the exact sort of obedience which was desirable in a chemical works was quite another matter, for such obedience was only too apt to become purely mechanical.

Mr. W. LANT CARPENTER desired to reinforce and confirm Dr. Gladstone's remarks as to the need of State aid for continuation schools; as also the absolute necessity for a larger and trained staff of inspectors, as suggested by Dr. Armstrong. Some such measure of State aid was very necessary for workmen and others who had not the means to spend the necessary time at school. Opportunities for acquiring such training were, no doubt, already offered by the organisation at South Kensington; but those opportunities would be greatly extended if, as he hoped, a Bill for establishing continuation schools should be passed this session. He would suggest that there was need for State aid in the direction of founding a large number of scholarships in connexion with existing schools, so as to give lads of small means and good brains the opportunity of devoting a sufficient time to getting a sound scientific education. He desired to press this latter point very strongly indeed. For example, in the highest grade of board school at Birmingham, where the fee was 9s., and a very good commencement of technical education was made (although legally the place was still an "elementary school" within the meaning of the Act), artisans who entered their sons there had to sign a promise that they should remain there for three years. This was found to be a very serious obstacle, for the family not only lost the lad's wages, but also had to pay this comparatively high fee for one individual among them. He was strongly of opinion that some system of scholarships and bursaries in connexion with our elementary schools was one of the most important directions in which State aid should be given to technical education.

Prof. R. MELDOLA wished to place upon record his views respecting the technical education question from the chemist's point of view. He might say at once, that the position taken by the Chairman of the Section was very similar to that which he held. It seemed to him an extraordinary anomaly in all proposed schemes of technical instruction that only the elementary side of the subject should be dealt with. In chemistry this state of affairs was particularly deplorable, because, in his opinion, it was a subject which admitted of no half measures. He failed to see how a smattering of elementary chemistry, spread broadcast among the boys in primary schools, was going to improve the chemical industries of this country. He did not wish to decry the advantages of introducing elementary science into primary school education, because nobody could be more alive than he was to the high value of science as a means of mental training; and he should strenuously uphold any scheme, by whatever name it was introduced, which was instrumental

in effecting such an introduction of science. The point he wished to bring out was, that the chemistry which it was proposed to introduce in this way was not, and could not in any sense be made, "technical," and that it was misleading to include such elementary science under the designation of "technical instruction." It might lead to a desire on the part of many schoolboys to advance further in the subject if they possessed any natural aptitude for it, and in so far it might lead to useful results; but why should the subject be smuggled in with the much-abused word "technical" attached to it? It might appear unnecessary to draw this distinction between chemistry in the early stage of its elementary introduction, and the subsequent application of the science to particular branches of industry, when it may then be said to become distinctly technical. There was, however, a reason, and a very grave one, why this distinction should be proclaimed, and it appeared to him that the chemical manufacturers were the only people who could proclaim it authoritatively. The reason for this necessity was that technical education, having so largely caught the public ear, had become almost identified of late years with purely elementary instruction, and had thus diverted support from the higher and more truly technical education, by which alone our chemical industries could be promoted. In this way the cause of true technical education was likely to be injured by having elementary, and always elementary, training pitted against it as a rival claimant for public support. The rivalry, if it existed, as he feared it did, had been created by the neglect of the true thing and the substitution of its shadow. All manufacturers would allow that we must begin with elementary instruction; but surely it must be conceded that if State aid is to be given in enabling boys at school to acquire a rudimentary knowledge of science, the more specialised application of that knowledge to industrial purposes, which could only be taught at a later period of education, had an equal claim to State support. The elementary training was useless so far as the improvement of chemical manufactures was concerned unless means were provided for efficiently converting that preliminary instruction into technical instruction afterwards. The two grades of instruction were, as it appeared to him, so inseparably bound together that to introduce the elementary grade only and to call that technical education was an abuse of terms.

He feared that the chemical industries were at a disadvantage in this matter as compared with other industries, because in many technical subjects which involve mechanical principles only there were numerous grades of training, each of which in its degree was of use to the man who had received it, and who wished to make his living by it. But an imperfectly trained chemist was on the same level, so far as chemical manufacturing was concerned, as the man who had received no chemical training at all. He could speak from experience on both sides of this question, having spent many years in chemical factories, and the last few years in imparting to students such knowledge of applied chemistry as lay within his power with the means placed at his disposal. It was most imperative that the chemical manufacturers should declare their views, because there could be no doubt that technical education was claiming more public attention than it had ever received before in this country, and there was a danger of the subject becoming identified with the mechanical industries—in other words, with manual training only—unless manufacturing chemists stated their side of the case. With respect to the practical application of the views he had ventured to express, it would be long, he was afraid, before the requirements for really

effective training in technical chemistry were adequately recognised in this country. He did not wish to alarm legislators at this stage of their efforts, but he had recently been collecting information as to the actual cost per head per annum that is considered necessary for the thorough training of technical chemists in continental schools, colleges, and polytechnics. The result showed how miserably inadequate were the existing institutions in this country to meet such competition as the continental establishments could bring to bear against them. In answer to the specific question proposed for discussion, it seemed to him, therefore, that if State aid is to be given at all for the promotion of technical education in chemistry, it should not be confined to elementary schools only, but should be extended to existing institutions, so as to enable the latter to specialise in an efficient manner the training which is given in the schools. And not only this, but if real service is to be rendered to the chemical industries of this country, the best way of doing it appeared to him to be to enable those students who have shown real ability in this direction to continue their studies for such a period as is necessary to turn them out as really efficient managers or foremen capable of superintending or conducting the manufacture of chemical products on a scientific method, as distinguished from empirical want of method. Some system of State scholarships or capitation grants might serve the purpose. In order to benefit our chemical manufacturers it would, as it seemed to him, be far more valuable to the nation in the long run to assist in the thorough training of the few who have shown themselves most competent, than to call upon the State to impart elementary instruction indiscriminately under the name of technical education. Such appeared to him to be the requirements of the time with respect to the all-important question of the promotion of those branches of manufacture in which chemistry is concerned.

The CHAIRMAN said that there appeared to him to be far more unanimity in the opinions expressed by the various speakers than was shown on the surface. In many points in which they differed it was in expression rather than in principle. Of course, if the Bills he had criticised were not intended to promote the objects actually expressed in them, that would make a great difference. And if the British public could be persuaded into thinking that it was getting technical education when it was really getting common sense, it might be desirable to let matters take that course. He could assure Dr. Gladstone that he heartily agreed with him as to the principles of education. It appeared to him that the meeting was tolerably unanimous on two points: (1) that in elementary schools there was great need of more practical teaching; and (2) that as far as chemistry was concerned, advanced education was needed rather than special training in elementary schools. He was as anxious as any one to give the workman who had brains a chance of rising; for the most learned and valuable men that England had produced had not always come from the highest classes of society. But what he dreaded was that a vast amount of public money might be wasted in a vain attempt to teach every lad in England what they were pleased to call technical education. To bring the discussion to a practical conclusion, therefore, he would move the following resolutions:—

- (1.) That in elementary schools there was great need of more practical training.
- (2.) That advanced education in chemistry is needed rather than special training in elementary schools.

Mr. LASCELLES-SCOTT seconded the resolutions, but suggested that the discussion should be adjourned until the appearance of the Bills in the improved form in which they were to be introduced this session.

The CHAIRMAN having pointed out that the discussion was for the guidance of the Council in case necessity for action should arise—

Mr. F. EVERSHEP moved as an amendment: "That in no direction is State aid needed for technical education in chemistry." He wished to point out that there had been no attempt made by the gentlemen who had advocated technical education to show that any of the industries of the country were languishing for want of it; that there was any great scarcity of chemists; or that if there was a scarcity such chemists could not be imported from Germany. The great variety of opinion expressed at that meeting was in itself a strong reason against any form of State aid. If such aid were given, it would necessarily be on some uniform plan, and that would interfere with those individual experiments in education which were now proceeding in various directions. He thought that there was much force in Sir Lyon Playfair's remark in a recent article on this subject (*see* "the Nineteenth Century" for last September) that it is very much better that different towns in different parts of the country should work out their salvation in their own way than that we should have one uniform system dictated from a central body. Uniformity would necessarily result from State aid. [Cries of No, no.] It seemed to him that manufacturers ought individually to be the best judges of the kind of chemists they required, and that their demand ought to determine the supply. If the manufacturer offered a good price for a good chemist that chemist would be forthcoming without State aid. In support of that view he referred members to Lord Armstrong's articles in the "Nineteenth Century" of July and November last. It ought also to be clearly borne in mind that in supplying chemists for manufacturers the State would be aiding one particular class of capitalists at the expense of the general body of tax-payers, and that would be a protective measure, equivalent to giving a bounty on the products of the manufacturer. If this were thoroughly realised by English manufacturers, who were an independent and self-supporting class, he thought they would be the first to repudiate the notion that they required such assistance. For these reasons he considered the meeting was not prepared to say that any State aid whatever was required for the technical education of chemists.

Mr. BERTRAM BLOUNT seconded the amendment, which was then put to the meeting and negatived by a show of hands.

The CHAIRMAN then put the first resolution, which was carried by a large majority.

The second resolution, after some further remarks, was modified, and carried in the following form:—

That as far as technical chemistry is concerned advanced education is needed rather than special training in elementary schools.

DR. F. HURTER IN THE CHAIR.

DISCUSSION ON TECHNICAL EDUCATION IN CHEMISTRY.

At the ordinary meeting held at University College, Brownlow Street, Liverpool, on February 6th, 1889, Dr. Hurter in the chair, a discussion of the question, "*In what direction is State aid needed to assist Technical Education in Chemistry?*" resulted in passing the following resolution, proposed by Mr. E. K. Muspratt, seconded by Mr. E. Carey, and carried with two dissentients:—

Resolution.—That this meeting is of opinion that it is not desirable to introduce special technical instruction in elementary schools, but that it is desirable that power should be granted to school boards or other local authorities to supplement the ordinary course of elementary education by a course of secondary education extending from the 12th to the 16th year, such education to embrace the technically important sciences (as defined in the Bill introduced on the 10th February 1888 by Sir Henry Roscoe and others) and modern languages.

Secondly, by endowing chairs of technical chemistry and allied subjects, viz., such as technical physics and engineering, furnished with the requisite staff of assistants at the various universities and colleges, possessing good laboratories, and by extending laboratory accommodation so as to permit of technical practice.

An amendment was proposed by Mr. J. W. Kynaston, and seconded by Mr. B. Kershaw, but no one voting in its favour except the mover and seconder, it was lost. The amendment was:—

"That it is undesirable to request State aid on the lines of the resolution proposed."

CONDENSED REPORT OF THE DISCUSSION.

The Chairman, Dr. HURTER, introduced the subject by reading from the two Bills dealing with technical education such portions as indicated what the promoters meant by technical education. He showed that the kind of education advocated by Sir Henry Roscoe's Bill was essentially that known in Switzerland and Germany as secondary or "real" education. He then quoted from Professor Lunge's paper on technical education of chemists, those portions in

which he (Professor Lunge) expressed his opinion that the best preparatory education for the technical chemist was that obtained in the "Real Schulen" of Switzerland and Germany and preferable to the so-called humanistic or classical education. Professor Lunge was himself at one time manager of works, and was now the head of the chemical department of the Swiss polytechnic school in Zurich, and therefore well qualified to form an opinion. Dr. Hurter then explained the Swiss system by means of diagrams. He showed that there, elementary education as a complete course was neither better nor worse than that given in English board schools. He was of opinion that, considering the early age of the pupils and the limited time from the sixth to the fourteenth year, nothing but what was now taught could possibly be taught, and he did not think that the ordinary labourer wanted more.

He then dealt with secondary or "real" education, which was open to all who by previous ability and by passing examinations had shown themselves capable of receiving a higher education with advantage, and he expressed his conviction that State aid would be best applied to the promotion of technical education in chemistry by establishing good secondary schools, which would provide a higher class of education for the better class of working men and artisans, and form a good preparatory course for colleges. He also advocated State aid for the endowment of technical chairs at the various colleges, so as to obtain some of the advantages of the continental polytechnic schools.

Mr. E. K. MUSPRATT, in proposing the resolution, said: That before moving the resolution, he wished to say that he agreed entirely with Dr. Hurter that it was not possible for chemical labourers to receive a better education than was now given in good elementary schools, and it had been the experience of Switzerland and Germany, nations which had most experience in education matters, that it was impossible to teach much more than those subjects which were indicated on the diagram. The great want in England was an efficient secondary education, and as regards chemists, he thought all of them were aware that the principal complaint was that they were deficient in a good high class secondary education. He was speaking of youths who had gone into such colleges as Owens, and attended the chemical classes, and who, when they left the college, knew just a little chemistry and nothing at all of other subjects. The reason seemed to him to be that the colleges received the students too badly prepared, and he thought that both Mr. Watson Smith and Dr. Campbell Brown would admit that their students frequently came badly prepared. (Dr. Campbell Brown: "Often not prepared at all.") The only remedy for this state of things was to improve secondary education. He was very glad Dr. Hurter had referred to Professor Lunge's opinion, as that gentleman had experience both as a manufacturing chemist and as the head of the chemical department of the polytechnic school of Zurich, and had better opportunities of learning what was required than any mere manufacturing chemist. Though there were eminent chemists, such as Professor Hofmann, who thought that gymnasium education (classical education) was preferable to "real" education, he (Mr. Muspratt) was inclined to agree with Professor Lunge, who had special technical knowledge. He thought it was most important for technical chemists that they should have the "real" education, because mathematics formed such an important element in that education.

Then as regards the higher education for those who wished for it, he thought that such institutions as Victoria University ought to provide as thorough a training as the polytechnic schools on the continent.

(He then moved the resolution given on page 335.)

Of course the wording of that resolution might be altered, but it fairly expressed the ideas which their Chairman had endeavoured to impress upon them, and in which he entirely concurred. By the endowment of chairs of technical chemistry and allied subjects, they meant that a thorough education for chemists must include something more than chemistry—it must include higher mathematics, engineering and physics, as a matter of course. He maintained that it was impossible for one professor to teach the higher branches of chemistry, educate a man practically for higher research, and put him at the same time through a course of technical chemistry. In the Polytechnic School, of which Professor Lunge was the head, there were many professors of chemistry; there were two head professors, one for theoretical, and the other for applied chemistry; they had each perfectly fitted laboratories, and the same system existed in all the polytechnic schools on the continent. In many cases they would find professors for special branches of chemistry, such as agricultural chemistry, &c.; indeed it was impossible to embrace in one professorship all that was required by technical chemists. He thought that the colleges would have to be aided to a considerable extent, for they were not likely to get sufficient endowments from private means. If they had to compete with the better educated nations on the continent in technical chemistry, they must have more aid given to higher education by the State.

Mr. E. CAREY seconded the resolution, and read a note from Mr. Norman Tate to the effect that he (Mr. N. Tate) had read the resolution and fully agreed with it, but thought it should be understood that technical chemistry included certain other subjects besides chemistry, such as engineering, building construction, machine construction, &c. Mr. Carey thought that was generally understood. He expressed himself gratified with the account the Chairman had given of the educational system in Switzerland, and wished they had some such system in England. He remarked how the people here seemed to grudge the money spent upon education, which amounted to some six millions per annum, whereas the United States of America spend 18 millions. He did not think that technical instruction should be attempted in elementary schools, nor that ordinary chemical labourers or furnacemen would be any the better labourers or furnacemen if they possessed scientific knowledge.

Better means of instruction were, however, urgently required for managers and proprietors, and such means should be provided from the general taxation of the country.

Mr. WATSON SMITH entirely concurred with the account the Chairman gave of the educational system of Switzerland, and spoke of the excellent text-books of science used in the Swiss elementary schools. The views regarding the education of workmen, expressed at this meeting, seemed to be shared elsewhere by the Sections of the Society. An attempt to give a technical education to workmen would be a mistake; a sound basis of elementary theoretical education was all that could be hoped for in the time at disposal.

He then spoke of the various institutions, such as the Science and Art Department, the City

Guilds of London, with the technical education they afforded, and the defects and failures to which they were liable, and made suggestions for their improvement.

Mr. J. W. KYNASTON had given much thought and attention to this question of technical education, and had arrived at conclusions which differed greatly from those expressed by previous speakers. It struck him as curious that they should be asked to adopt a resolution requesting State aid for technical education, while at the same time the Chairman had told them, and all the speakers in the debate agreed with it, that the working man must be excluded from the benefit of such education. Was it reasonable to suppose that Parliament would consent to the application of general taxation in aid of a scheme from the benefits of which the great bulk of the ratepayers were to be excluded? In other words, it was proposed to raise taxation from the lower classes for the benefit of those in a higher sphere. He did not like to move an amendment as he considered it would be a great advantage if professors of technical chemistry were appointed in the various manufacturing centres, but he felt that the cost should be borne solely by those who were to be benefited by the instruction. He quite agreed with Mr. Carey that a workman at a suitable furnace would produce no better saltake if he knew that the formula of sulphate of soda was Na_2SO_4 , and he was satisfied that all that was necessary to regain and maintain the supremacy of our manufactures was, that the operations should be directed and controlled by men more thoroughly educated for the work. In this country a man without any special knowledge of the scientific principles involved would often become a chemical manufacturer, though quite unable himself to control such a manufacture, and was often not careful to place men in charge who had specially qualified themselves to occupy such a position, and indeed had often little or no sympathy with men of scientific attainments. He concluded by moving the following amendment:—

"That it is undesirable to request State aid on the lines of the resolution proposed."

Mr. KERSHAW seconded the amendment. He agreed with Mr. Kynaston's views. He admitted that foremen would be better able to discharge their duties if they had technical instruction. He thought it would be better to give them this instruction only after they had shown their fitness as foremen by possession of such qualities as reliability, truthfulness, and steadiness.

Dr. J. CAMPBELL BROWN opposed the amendment on the ground that State aid for technical education was not taxing one class for the benefit of another, but was taxing the whole community for the benefit of the whole. If State aid were given in the absence of sufficient aid from other sources to promote the education necessary to enable chemical industry to be carried on as well as or better than in other countries, that would not be benefiting one class at the expense of the whole, but it would be benefiting the whole at the expense of the whole community. He suggested that the resolution should include other subjects besides technical chemistry, and should also provide for assistants to the professors for whom State aid was needed quite as much as for professors. He referred to the Massachusetts Technical College, where they had 17 teachers of engineering, 15 of chemistry, and seven of physics, not at all too many; he did not think Massachusetts was a greater place than Lancashire. They wanted efficient assistants if practical teaching were to be carried out properly. He entirely supported Mr. Muspratt's resolutions.

Mr. W. P. THOMPSON said that Mr. Kynaston had spoken of it being unfair that one class should benefit more than another from State aid, but nearly all the public money now voted for education had been spent on the lower classes. The middle classes particularly were handicapped by having to pay rates towards supporting schools, while they were obliged to send their children to private schools. He did not think that the very lowest class did pay the largest amount of taxes, and in any case it was only fair that some of the crumbs of the Government should go to the other class that had to pay taxes as well as the lower class, and secondary education was helped less by Government than any other.

Dr. HURTER said the reasons which Mr. Kynaston had urged against State aid were selfish. A good State-aided secondary education should of course be open to all. The Swiss would not have such a good system of education if it were not State aided; indeed, it was entirely free education. The working men benefited quite as much by the proficiency of the upper classes in any particular industry as those classes themselves. Mr. Kynaston's argument, that it was the proprietors who should be better educated, was an argument for the establishment of secondary schools. Where otherwise were they to get this better education? As regarded Mr. Kershaw's views that education should be given to foremen after they had entered upon the duties of foremen, he thought it would then be too late. The knowledge should be available when they entered on such duties.

Mr. E. CAREY hoped his remarks had not been misunderstood. He would give every facility to working men to better their position and to increase their culture and happiness by knowledge. He merely intended to convey his opinion that technical education would not be of advantage to a labourer as a labourer, and that, therefore, such instruction need not be given in elementary schools.

Mr. E. K. MUSPRATT drew attention to the fact that the question of the Council was entirely lost sight of by Mr. Kynaston. The question Mr. Kynaston was discussing was a political one, viz.: whether it was desirable to aid higher education by State grants. Mr. Kynaston was of opinion that it was not. The experience of England had shown that elementary education had not come up to the level of elementary education on the continent until the State contributed to that education. Then when it was found necessary to spread an idea of science among the people, the State again gave its aid through the Science and Art Department. There was not now a civilised country in the world that did not contribute State funds for education. In democratic countries, such as America and Switzerland, the people were content that State money should be directed towards higher and technical education. But the question which they had to decide that evening was only in what direction the State could assist technical chemistry; they had not to indicate the source whence the State should get the money; all they had to do was to say in what manner State aid could best be given.

Mr. KYNASTON and Mr. KERSHAW shortly replied.

The CHAIRMAN then put the amendment. Only the mover and seconder voted for it, all the other members against.

On the resolution being put, all, with the exception of the mover and seconder of the amendment, voted for it.

DR. BAILEY, F.C.S., IN THE CHAIR.

DISCUSSION ON TECHNICAL EDUCATION IN CHEMISTRY.

THE CHAIRMAN: I have been called upon at a moment's notice to take the chair in the absence of Dr. Schunck, and the chief business on the agenda is a discussion in order to elicit opinion on the question "In what direction is State aid needed to assist technical education in chemistry?" The Council has brought this subject before the different Sections for discussion in order that any steps which may be taken later on will have more weight than they otherwise would. The particular view before us is in what direction is State aid desirable or even (I suppose) undesirable in advancing technical education. You are all aware that Bills have been brought before Parliament, and, as far as my own feeling is concerned, I rejoice that they have fallen through, as they were quite incomplete and inadequate to deal with the question. A grave mistake was made in the Bill in regarding technical education as a matter to be dealt with by our elementary schools. No greater mistake could have been made. If anything is to be done in this direction it must be done in the way of erecting first in one great centre, and afterwards in others, thoroughly efficient technical schools. We do not want our school boards imbued with technical education, but what is required is a place where our chemists can receive a thorough and efficient technical education in their special subjects. If such an institution can be set up in Manchester, other towns will soon follow the example. Whether Government should be asked to assist in this matter or not is a question to be considered to-night. One method of securing a satisfactory solution of the question is to enlist the assistance of those who are actually engaged in the work of technical education, and to give them a hand in framing the Bill. Institutions should be established in different centres suited to the special trades and industries of the district. For instance, Manchester would require something different from Liverpool or Birmingham, and the proper way to solve the problem would be to form a guild of chemical manufacturers in conjunction with existing educational bodies with a board of reference in London similar, in its relations to the Local Government Board, to boards dealing with other matters.

MR. WATSON SMITH: In the first place the term "technical education" has gradually been made to cover so much, because so little understood, and therefore applied to one thing by one man, and to another thing by another, that at last it is indeed hard to say what education is not technical. The work of the Science and Art Department, for example, is brought under this category, and we find, in one typical instance that occurs to me, a noble building erected as a technical college; but in that building the work of education done by the science and art master is in preparing his students to pass the South Kensington examinations, just as they might be prepared in our central board school in Deansgate. True there are technologists also there, but they are subordinate to the South Kensington master, who acts as principal of the said college, and who, rather than his best pupils should go to the technical masters proper, strives to induce these pupils to work for higher passes, or go in for national scholarships at South Kensington. The pupils working for the South Kensington examinations are not undergoing, strictly speaking, technical education. They are laying an educational basis for the reception of it rather, and it is the recognition of this fact that has led the authorities and examiners of the City Guilds of London Institute to insist that a candidate for their full certificate in any branch of technology should first obtain passes in certain science subjects of the Science and Art Department. Suppose a student of the Science and Art Department has gained a national scholarship, why should he be obliged to go to the Normal School of Science to work it out? Why should he not be allowed to go, if he so desire, to some other college of good standing, or some technical college? In the case of the college to which I referred, why should not the student, if he so choose, work out his scholarship in the technological department? Seeing that the education of this country as regards the branches fundamental to technical instruction is so much in the hands of South Kensington, I see grave difficulties in the way of giving true technical education as a finishing course in the future technical institutes and colleges. Two circumstances will prevent any but the "base residuum," so to speak, of the Science and Art Department students from entering the technical colleges. (1.) They will be persuaded by their science and art master to keep with him, if worth retaining at all, to earn more grants for him, more honours for themselves, and haply a national scholarship to be held at South Kensington. (2.) They are naturally tempted by the brilliant chances held out, and if they do not get the scholarship they will at least get high passes, and so make up their teacher's income. But let them get to South Kensington and what do they learn? To become scientists rather than technologists, more probably to become teachers. In some respects it is good that the teachers should be paid by results, and doubtless the Science and Art Department has done grand work; but there is a dark side, as I suppose there always is, in the mere strenuous effort to pass examinations. Such education is apt to be very one-sided; however, that is not my point just now. My question now is: What should the Government do in the way of aid? The reply is: Authorities appointed by Government first organised the South Kensington scheme of science and art examinations, let them now, discriminating between educational foundation and the superstructure to be erected upon it, balance the one with the other, let them take hold of the subject of true

technical education with the technological subjects involved, and co-ordinate the one scheme with the other. At all events, let them so balance matters that the national scholarships, &c. may not only be held at South Kensington but at other colleges, and especially technical colleges and institutes. Let the science and art teachers also receive bonuses and grants for enabling their pupils to pass the entrance examinations into these colleges and institutes. Supposing this done, what next? I have said that the Science and Art Department teacher, if a good man, can make a comfortable income on his grants, even without any special practical experience. But the technological teacher, to be efficient, must possess the scientific knowledge, the theory, and also have spent some years of his life in the works and office. Now, (1) must the latter not be adequately paid then? (2) If paid adequately, where is the money to come from? Where also is the money necessary to provide and equip his department to come from? The practice of bequeathing large sums in support of chairs of arts and sciences, &c., is all very good and noble, and is regarded with astonishment on the Continent, but it produces very unequal and very unfair results. Is a whole section of the country to wait for adequate instruction in the principles and practice of chemical technology, chemical engineering, &c., through a generation, because some 15,000*l.* or 20,000*l.* is not forthcoming from private munificence to establish a department and found a chair or chairs in the above subjects? Some means should be adopted to ascertain where it would be advisable to establish departments of technology with proper qualified teachers or professors. These professors or teachers ought to be selected by a Government sub-committee, so that properly qualified men be appointed, and not scientists and theorists, however good and eminent, who have not also served and gained real practical experience in works and offices. I will not trouble to argue with those who say that the professor of pure chemistry can easily read a few technological books, visit a works or two, and then teach chemical technology and its principles forthwith, but I will ask them to turn to the papers in our Journal, by such men as Dr. Hurter, Walter Weldon, Alexander M. Chance, Ivan Levinstein, Lewis T. Wright, and others, and consider the amount of toil and years of practical work necessary for such adaptation of theory to practice. Yet these men, eminent as technologists, would need a special course in the essential principles of the art of teaching, in order to instruct youths who are so far only conversant with certain principles of pure science. Now it is an easy thing to write a paper for our Journal, but it is quite another matter to write out and prepare a course of 20 lectures on some branch in chemical technology. If we are to have technologists like Lunge, Stahlschmidt, Winkler, Post, and Engler as professors in the technical colleges of this country, we must offer them an adequate inducement, just as continental Governments do. To sum up, then, the directions in which State aid is needed, are (1) In raising the City guilds or similar systems of technical examination work to a co-ordinate rank with the South Kensington Science and Art Department examinations, so that they can co-operate; (2) In founding departments, chairs, lectureships, and colleges of technology, in such places as a Government committee of inspection, hereafter to be appointed, with power to examine into the cases of existing colleges and institutions, and to report, should recommend; (3) That the said Government committee of inspection should be formed principally of practical men,

chemical or other manufacturers as the case might be.

I cannot conclude without heartily commending to the notice of our members the sixpenny Abstract of the Report of the Royal Commissioners, edited by F. C. Montague and prefaced by Sir Bernard Samuelson. That preface, and the conclusion by Mr. Montague, contain most important suggestions.

Mr. GRIMSHAW said: I am not sure that we have in the discussion on technical education in this country reached that point at which we are prepared to say exactly what practical steps ought to be taken in the cause of such education, and if that be the case, to dogmatise too severely upon the way in which State aid should be applied is not desirable. By technical education in chemistry we mean, I presume, the scientific inculcation of that knowledge which is necessary to carry on those manufactures in which chemical reactions are involved, and it appears to me that there are in this country two necessities which need supplying in regard to this technical education. One is the teaching of our chemical manufacturers something about the theory of chemistry, and the other is to teach professors of chemistry something about chemical manufacturing, and it is difficult to decide in which direction the denser ignorance prevails, and the more enlightenment is needed. During the few years in which the cry for technical education has been heard in England, the prevalent notion appears to have been to educate in "chemical theory" those who were engaged in "chemical practice," tacitly assuming that this was the chief or only want. Now, to-day (thanks to the course of agitation on these lines) it is becoming evident that those engaged in chemical practice are scarcely so much behind in knowledge of theoretical chemistry as our scientific chemists are behind in knowledge of the details of manufacturing practice. In spite of a few brilliant exceptions, known to most of us, I must candidly say that I believe the want of familiarity of the professor with the works is to me more startling perhaps than the ignorance of the manufacturer with regard to chemical theory. There certainly would appear the superiority of our German competitors; and the constant contact of the German teachers of chemistry with what is going on in the manufactories is to my mind the chief element which has given them those advantages over us which have been exhibited in recent years. We have, therefore, to educate the manufacturer and the professor. Who else is in need of technical education? The manager, or foreman, or the workman? Which of these is to form the "corpus vile" for our technical educationalist, because upon our decision on this point will largely rest the kind and degree of State aid to be asked for. For myself, I have, I think, finally discarded the idea of technically educating the workmen of our chemical manufactories. I do not see how you are going to do it, and I do not see what you want in a workman beyond sobriety, industry, and general intelligence. If you say that he must have technical education to make him "generally intelligent," then I do not agree with you, and I fancy that you and I do not mean the same thing by the expression "general intelligence." At any rate I assume, for the present argument, that the right kind of workman for chemical works will be produced by intelligent elementary education, and subsequent work in his younger days in an intelligently managed manufactory, under capable foremen, and highly educated masters and owners. With regard to foremen and managers of departments the case is altogether different, and here I assert that a great and growing necessity exists.

Speaking in a general sense, we have no institutions in England where a sound chemical education can be obtained suited to those who are to become our analysts and foremen in chemical works. It is difficult to name an institution where instruction of the exactly right kind can be had, and certainly where it is to be had at a sufficiently low cost to make it feasible to the class of men we are considering. It seems to me, therefore, that it is at this point that your State aid may come in. I do not intend, nor am I competent to pronounce as to the exact mode of application; but if the assistance of the State can be called in to create teaching institutions to come in somewhere between our mechanics' institutes and our colleges, I think we shall have partly solved the problem of where State aid may be profitably employed in forwarding the chemical industries of Great Britain. Whether these State-aided institutions shall be enlargements of our mechanics' institutes, or be developments or off-shoots of our colleges, is a matter of consideration in individual localities; but what I claim ought to be the object is the production of educational facilities for the foremen and analysts employed or to be employed in chemical works to render themselves competent, and to give the exceptionally intelligent workman a fair chance of qualifying himself to enter upon those duties which are performed by the foreman and analyst. With a subsidy from the State and the creation of a body of teachers who are in intimate touch with manufacturing processes, institutions having the functions I have alluded to would in a comparatively short time give such a stimulus to the chemical industries of Great Britain that we should then take, what by our natural advantages we are cut out for, the very first position among countries in which those industries exist.

MR. GEORGE E. DAVIS: I thoroughly agree with all Mr. Grimshaw has said.

MR. WM. THOMSON: It seems to me that in this matter it is one country against another, and that being so I think that technical education should be given not merely to managers and foremen as had been suggested, but to the whole of the workpeople. The first thing needed is to teach them to understand English and a certain amount of mathematics and algebra. At the present time the average British workman cannot follow any instructions given him in writing, much less read a drawing. When that kind of education to which I have referred has been well grounded, then the recipient of it is ready to qualify for any special branch of manufacture or industry, and I think State aid should be granted to supply apparatus by which the actual laws of nature might be demonstrated, rather than to give rewards for passing examinations.

MR. G. CAWLEY: I agree with Mr. Grimshaw that all that is required of the British workman is sobriety, intelligence, and industry, and that technical education rather concerns masters and managers; at the same time I admit it is very difficult to say what is the best thing to do with regard to technical education, as I do not think it has been very clearly defined what that means. No doubt the technical education of the chemist is a very different thing to that of the engineer. It seems to me that what is wanted is a council of the leading chemical manufacturers in certain districts, and that they should decide as to the character of the school or college necessary, and that they should arrange for the students to spend a certain time in their works, who would thus acquire a practical as well as theoretical knowledge. I agree with Mr. Thomson that mathe-

matics and drawing are subjects which are very much neglected, as I do not think that more than 50 per cent. of the chemists are able to make a scaled drawing from which chemical engineers could make plant, and I think also that in chemical colleges or schools this should form one of the subjects to be taught. Judging from our knowledge of South Kensington I think State aid for technical colleges is a thing to be avoided.

MR. THOMSON then suggested that the meeting be adjourned for a week in order to give members further opportunity for reflection.

MR. CARPENTER: The matter came up at the November meeting of the Council, it being thought desirable that a discussion should be held in each Section, so that we might be prepared, if necessary, to send delegates to lay our views before the Council when the Bill is re-introduced. It seems to me that a vote might be taken to-night as to whether Mr. Watson Smith and Mr. Grimshaw represent the feeling of the meeting. I therefore propose that these two gentlemen do represent this Section for any action which the Council may wish to take in this matter.

MR. GEORGE E. DAVIS: The question on the post-card seems to assume something which has not been mentioned before—"That State aid is needed to assist technical education in chemistry." There is no doubt that the question has been carefully formulated, and perhaps there are some members here who will be able, in their own mind, to discover what it really means. So far as I am concerned I think the views set forth by Mr. Watson Smith and Mr. Grimshaw represent what the manufacturers think of the question. I have, therefore, very great pleasure in seconding the resolution proposed by Mr. Carpenter.

MR. ESTCOURT: I second Mr. Thomson's motion for adjournment.

THE CHAIRMAN: It has been proposed that this meeting stand adjourned in order that the points which have been raised may be put into definite form. Whether we are expected to carry a resolution does not appear to me to be very clear from the notice issued. We have on one hand a proposition that the meeting be adjourned, and on the other hand that the views expressed at this meeting are the feeling of the Section. We might gain some advantage by adjournment, but at the same time I think that if Mr. Carpenter's resolution were to take the form of appointing a small sub-committee to represent the views of this Section to the Council, it would meet the case.

MR. THOMSON: I should like the question to be more clearly defined. Is it proposed that State aid be given to the higher classes and not to the lower?—that is to say, that you will educate the masses up to a certain point and not try to take them any further?

THE CHAIRMAN: We have before us two views of technical education, one in favour of the lines laid down by Sir Lyon Playfair, and the other as set forth by Lord Armstrong. I think what is meant by the question put by the Council is, "Can you, as a body of experienced men, suggest any definite directions in which State aid is desirable for promoting technical education in this country, respective or irrespective of the people who receive it?" If the delegates can go before Sir William Hart-Dyke with some well-defined suggestions I think they would have a better chance of succeeding in their object.

A show of hands being taken on the motion for adjournment to admit of further discussion, 14 voted for it and 15 against.

The following resolution proposed by Mr. Carpenter and seconded by Mr. Davis was then put to the meeting and carried by a majority of 16 to 11:—

"That in the opinion of this meeting the views expressed by Mr. Watson Smith and Mr. H. Grimshaw are the aims to be kept in view by the State in creating and aiding, in various parts of the country, institutions for education in technical chemistry; that they represent the views of this meeting, and that these gentlemen be instructed to act as representatives of the Section to the Council."

*Meeting held in the College of Science,
Thursday, March 7th, 1889.*

MR. T. W. STUART IN THE CHAIR.

DISCUSSION ON TECHNICAL EDUCATION IN CHEMISTRY.

THE CHAIRMAN opened the discussion by announcing that the Council had desired an expression of opinion from the various Sections on the question of the desirability of State aid to technical education so far as the chemical industries were concerned, and the direction which that aid, if thought desirable, should take. He called on—

Mr. G. T. FRANCE, who said that the general question of State aid to technical education was a very wide one, but that the limitation of the discussion to its bearings on the chemical industries narrowed the question very much, and made it much easier to come to some definite decision on the point. At present, Government aid is given to public elementary schools, higher grade schools, and to some extent in grants to science colleges. Boys in the elementary schools must pass certain standard subjects first, and can then take specific subjects.

Considering the age at which boys leave the elementary schools, it is clear that nothing can be done in the way of teaching chemistry there, so that for present purposes they may be dismissed. Higher grade schools, whether under school boards or under denominational government, are comparatively few in number; the cost per scholar may be about 6*l.* a year, of which, perhaps, 2*l.* is covered by fees, 2*5s.* by grants from the Education Department, and the rest comes in the way of grants from the Science and Art Department. These are made on the results of individual passes in the May examinations held by the department, and any boy is at liberty to take up and pass in any of the 24 (?) subjects of the department's syllabus. How far is this profitable as regards the teaching of chemistry? Boys in these schools do "standard" work until they pass the seventh standard, and then take up some of the "subjects" of the Science and Art Department. Experience of the working of these higher grade schools shows that there is always a tendency on the part of the teachers and managers to teach as many subjects as possible, for in that way is it possible to earn the largest grant. A boy at the Manchester High Grade School, under 16 years old, had in one session taken first class certificates in 12 subjects, earning 24*l.* The tendency is towards a simple system of cram. The money granted under this system (415,000*l.* in the past year) might be devoted to much better purpose. He would abolish the present system of examination altogether, and instead of individual passes as a basis for payment, he would have the teachers properly qualified and certificated, and examine into or inspect the average character of the work, and the quality and methods of the teaching. The teachers would then feel themselves free to do their best work, and would have no such strong incentive to cram as at present exists. Good science teaching could thus be established in these schools, but he questioned whether much time could be profitably devoted to chemistry, considering the age at which boys leave. Passing by grammar schools, high schools, and the larger public schools, as being unconnected with the Government, Mr. France next considered the various science colleges. To these, he thought, with their highly qualified staff of teachers and their equipment for the work, Government aid might be profitably extended. He did not think it desirable to enter at present into details, but he thought some plan might be devised for carrying on promising pupils of the secondary schools, by exhibitions or otherwise, into these colleges, and that money devoted to such a purpose would, so far as teaching chemistry was concerned, be much more profitably employed than under the present system.

Mr. JOHN PATTINSON thought that abundant facilities for learning the elements of the science exist, and that what is wanted is to enable people to carry their knowledge further and deeper. Complaint is made that in England insufficient attention is paid to the teaching of pure science, and to the training of chemists in research; that to encourage manufactures, trained chemists are necessary, and that this kind of training is carried much further in Germany than here. He thought that the elementary and higher grade schools and the science classes connected with South Kensington, went in the right direction, but not far enough. Institutions to carry on higher work were never self-supporting, and could never be expected to be so, and in his view the best thing that could be done would be to subsidise such institutions. He concluded by moving the following resolution:—"That in the opinion of

this Section further State aid for promoting technical education in connexion with chemical industries can be best bestowed on colleges of science where the principles of chemistry and methods of chemical research are fully taught."

Mr. MATHER agreed with the principle of subsidising colleges of science. He thought that Mr. France hardly gave South Kensington sufficient credit for the work it was doing.

Mr. B. S. PROCTOR thought it was difficult to speak very decidedly. His experience in many respects led him to agree with Mr. France, and to see the many evils in the present examinational system, which undoubtedly tended to cause teachers to devote attention to those pupils who were likely to bring fame and emolument by prize taking, and to neglect those who were not. It also tended to teaching with the evident and even with the avowed object of enabling the student to pass the prospective examination. At the same time he recognised that these classes were doing a large amount of good work in the country, and he feared that to do away with the examinational system would be likely to do away with the classes altogether. He thought, however, no difference of opinion could exist as to the desirability of giving support to science colleges, and he seconded the resolution. A scheme might probably be devised whereby, besides direct support to them, promising students from the South Kensington classes might go with exhibitions to the colleges, and that the teacher who recommended these students should have no pecuniary interest in their success. Still retaining the present system of elementary science teaching, he would in addition subsidise science colleges and endeavour to improve the teaching.

Mr. LOVIBOND supported the resolution. He thought the best place for chemical training was a college of the nature of that in which they met, and nearly all such colleges throughout the country were starved for want of money. He should have been pleased if Mr. Pattinson had added to his resolution some disapproval of South Kensington *methods*, though he quite recognised the good which was done through its agency. He gave an amusing instance of the weakness of its regulations as to the qualifications of teachers, by quoting the case of two children, aged 12 and 14, who having passed the examination at the end of a course of University Extension Lectures on Chemistry in a Midland town, became qualified to teach elementary chemistry under the department, and earn grants.

Dr. BEDSON, who was not able to be present, sent his views, in the shape of a letter to the Secretary, of which the following is an abstract:—The question turns upon the meaning to be attached to the words "technical education," so far as the chemical industries are concerned. The history of their development during recent years shows us that not only for the initiation of new processes, but also for their carrying on and improvement, men are wanted who have been trained in the same school as the initiators and discoverers of new processes; that is, who have received a sound training in the principles of chemistry, and have been made practically familiar with the methods of research—have, in fact, shown their capability as investigators. In seeking for an explanation of the fact that industries such as the coal-tar industry had made their home in Germany, though both raw materials were found, and finished products were used, in this country, he adduced, as

one important factor, that there already existed in Germany a large number of trained scientific workers, the German universities having recognised the importance of scientific training, and not having, like our universities, kept it subordinate to the older studies of classics and mathematics. This teaching of the German universities, and the supply of men competent to undertake the prosecution and development of such scientific industries, gave Germany a start in such enterprises, and we have in this country tried to overtake her. The most important step in this direction has been the formation, by private munificence, of university colleges, attempting to give an education in all departments of knowledge. These exist in (probably) sufficient number to supply the present educational needs of the country; but they all are cramped by want of funds, and prevented from giving such an education—similar to that given in the universities of Germany—on terms which would bring it within the reach of all those able to profit by it. It can never be hoped that private munificence will be equal to the task of finding means to place all these colleges on a sound financial footing; and the only direction in which a solution of the difficulty is to be found lies in Government support being given to them.

The CHAIRMAN supported the resolution, thinking the best way would be to appoint a committee to investigate the position, circumstances, and needs of the various colleges, and equitably adjust the money granted. He adverted to the good work done in the classes connected with South Kensington in fostering a taste for physical science among those who otherwise would have had no opportunity of commencing its study.

Mr. STEAD also supported the resolution, but did not concur with Mr. France in condemning the system of the Science and Art Department.

Mr. SOWERBY also spoke of the good work done by the South Kensington classes, stating that many boys in his works attended such classes, and derived some considerable advantage from them. He claimed that, as part of the examination in chemistry was practical, they were to that extent free from the imputation of cram. He thought that we were already well provided with the means for teaching pure chemistry, and that what was at present sought was information as to the teaching of applied chemistry. He saw no reason why such institutions as the College of Science should not be self-supporting, provided a sufficient number of students availed themselves of their advantages; and he instanced the very large number of students attending corresponding institutions on the Continent.

Dr. DUNN supported Mr. Pattinson's resolution. He concurred also very strongly with the remarks of Mr. France. A long and varied teaching experience had convinced him that along with the undoubted good which accrued from the present system of the Science and Art Department there was a large amount of positive evil. He had formerly for some years taught classes under the Science and Art Department, and had been able to observe very closely the working of other classes besides his own, and could not help noticing the very strong incentives which existed towards cram and rigid adherence to the published syllabus on the part of the teacher, and towards mental dissipation and certificate-hunting on the part of the student. He was very strongly of opinion that as the more elementary chemical

teaching of the country was, and probably would be very largely done in classes of this kind, some reform was urgently needed. It was, perhaps, premature to go into details, but undoubtedly the direction in which progress would be made, would lie in abolishing the present examination system, insisting on a much higher qualification in the teachers, and having secured well-qualified men, to trust them and leave them free to as great an extent as possible, having examination or inspection of the general efficiency of the classes, and the methods of teaching. Mr. Lovibond had given an example of the absurdity which the present system might result in, and his (Dr. Dunn's) experience throughout his connexion with Science and Art Department classes had been that teachers wishing to qualify themselves to earn payments on the results of teaching science were the worst class of students he had, showing no enthusiasm in their work, but doing as little, either in the way of attendance or work, as they possibly could without disqualifying themselves. The reason for demanding no higher qualification in the teachers which existed when the system was yet an experiment, that at first such teachers had to be taken as could be found, no longer holds now when facilities for sound scientific training are so multiplied; and the only way in which to secure better teaching is to demand and to pay more highly qualified teachers. Were these classes reorganised so as to minimise the objections to them, they would lay a sound foundation of elementary science, on which the science colleges could build without having to raise and reconstruct. The endowment of these colleges, and the remission of fees or foundation of exhibitions there for distinguished students of the elementary science classes, would provide the highest chemical training for all those who had shown the likelihood to profit by it. He objected to Mr. Sowerby's contention that instruction in applied chemistry was wanted, urging that special training was impossible except on a basis of general principles, and that a highly trained chemist was able to apply his knowledge and ability to any branch of applied science.

Mr. FRANCE urged that Mr. Pattinson's resolution did not go far enough. He would not propose to do away with the South Kensington classes, but he thought that the money spent on them at present might be made to do a much greater amount of good, and it would be much more likely to gain the ear of a Government if a proposal went up to them showing how to redistribute more effectually the money they already spend; it would be more likely to have effect than merely asking for more.

Mr. PATTINSON agreed to modify his resolution so that it should read:—"That in the opinion of this Section, State aid for promoting technical education in connexion with chemical industries can be best bestowed on colleges of science where the principles of chemistry and the methods of chemical research are fully taught, and that a portion of the money now devoted by the Science and Art Department to payments on the results of the May examinations might be more profitably used in the above direction."

The motion was unanimously agreed to.

MR. E. C. C. STANFORD IN THE CHAIR.

DISCUSSION ON TECHNICAL EDUCATION IN CHEMISTRY.

THE CHAIRMAN explained that the discussion was held at the request of the Council of the Society, who were desirous of initiating discussions in all the Sections, so that the hands of the Government might be strengthened by giving some idea of what manufacturers wanted in the shape of technical education in chemistry. He then called upon Sir John N. Cuthbertson, Chairman of the Glasgow School Board, to open the discussion.

SIR JOHN N. CUTHBERTSON said that in his opinion technical education was not instruction in any particular chemical manufacture, but was instruction in those scientific principles which a young man would find necessary in the prosecution of some art or manufacture. While he did not feel qualified to say in what direction State aid ought to be given to assist technical education in chemistry, he was able to say what was being done at present, and what opportunities there were for the study of chemistry in Glasgow. There was the University, the West of Scotland Technical College, and in the primary schools of the city and suburbs under the school board eight well-equipped laboratories, besides six or eight lecture rooms fitted up for the teaching of science. At these laboratories and lecture rooms in connexion with the school board there were at present 174 pupils working in the laboratories and 596 attending the day and evening classes. Besides these there was also several private laboratories. The State aid at present being received by the Technical College and the school board was chiefly derived from the Science and Art Department. That department granted upwards of 7,000*l.* a year for the encouragement of science and art in Glasgow, about one-third for art and two-thirds for science. The West of Scotland Technical College received about 4,000*l.* a year, much of which was devoted to chemistry. The school board received about 2,000*l.* a year, the School of Art about 600*l.*, and 1,000*l.* went to other institutions. Faults were sometimes

found with the administration of the Science and Art Department, but so far as his observation went it was fairly well managed, and was always willing to receive suggestions. If he were to make any suggestions, they would be two—first, that the procedure of the department should be simplified, and, second, that far more aid should be given to the advanced classes. The elementary classes received abundant recognition, but not so the advanced. His opinion was that at present there was as much technical education as there was demand for. He believed that if these different organisations he had described were allowed to have full swing, and a moderate amount of Government support, they would cover the whole ground.

Professor DITMAR, taking "technical education in chemistry" to mean such instruction in the technicalities of chemical industries as might with propriety be superadded to a full course of chemical instruction, said his answer to the question was very simple. The State certainly had the duty of affording to every young man in the country the opportunity of receiving sound instruction in chemistry as in other sciences, and this, in the case of chemistry, included laboratory teaching, at a moderate expense; but he did not see that it was bound to provide the means for special instruction in certain trades. If the dyers and calico printers in the West of Scotland felt the want of a special school for their trade, why did they not set up one at their own expense? 2,000*l.* a year would be plenty, and dividing this by the number of firms concerned, they arrived at a quotient which some of them would find it *indefinitely* to pay. The Tennants of Wellpark alone could well afford to keep a brewer's school going; the expense would be a mere trifle to them, and it would be less than a trifle to Bass or Allsopp. There was no need of multiplying examples. It would be immoral to tax the people for the foundation and maintenance of such technical schools. But then some might say, why not found a grand chemical school, where all the several branches of chemical industry would be taught technically? His answer was that such a chemico-technical university, as one might call it, would be an impossibility. It would demand a very large staff of teachers, and that of teachers of a kind which it would at all times be very difficult to get, and quite a series of chemical laboratories. Supposing the corresponding immense outlay of money to be risked, he felt quite sure that this university would inevitably drift into the position of a school for this or that speciality, or one or two specialities, or if it maintained its original pretensions would soon come to be looked upon as a miserable fraud. Regarding the grants of the Science and Art Department, if they had done good, they had also done much harm, for they had given rise to a system of mere cramming. He pointed out also that the teaching of science to boys about 14 or 15 years of age was a great mistake. How could they learn science if they had at the same time to learn history, French, German, and mathematics?

Mr. ALEX. WHITELOW said he quite agreed with Sir J. N. Cuthbertson in regard to the necessity for the Science and Art Department encouraging the higher subjects in chemistry. Regarding the general subject of technical education, he had always believed that a thorough grounding in the science of chemistry was the only basis of technical education. A man who had thoroughly studied the subject theoretically would be suited to go into a works and give his attention to special departments. He thought that if the Government would aid such colleges as the West of Scotland Technical College to give students the opportunity of experimenting on a large practical

scale, it would be a great help to the development of technical education.

Professor MILLS said that it was alleged in some quarters that education in technical chemistry was not required, and that a strictly scientific training—followed by immediate transition to the workshop or factory—was the best programme for a young technologist. His view was, on the contrary, that, after the rudiments of chemistry had been acquired, the intended manufacturer should be handed over to some who would teach him, in a thoroughly scientific spirit, the nature of large-scale processes, and who would, by continued suggestion, awaken in his mind the growth of technical ideas and the tendency to create new things. He was gratified to find, in the form of the summons to the meeting, that the Council of the Society took it for granted that education in technical chemistry was required, it being proposed to consider in what direction was State aid needed to assist it. The first consideration that arose was: Over what area was the proposed aid to be extended? This, in his opinion, was much more limited than at first sight might be supposed. Most of the work in chemical manufactories was executed by unskilled persons, whose business it was to carry out simple orders in a fairly intelligent manner. Technical education could be of no use in such hands—indeed, very few employers of labour would consider it desirable that their workmen should be trained to form opinions on the methods employed in the works. Thus, then, there remained only the skilled labour—the higher class foremen and assistant managers of departments, constituting much under 4 per cent. of the wages expenditure of the works. These could not leave their business during the day, but many of them would be willing to attend evening classes in their special subject, namely, for the purpose of getting ideas, and not for the purpose of eventual examination. Such classes might be held in all their large provincial colleges, and the State might well aid them by a grant of part of the expense of models and other illustrations, part of the lecturer's salary, and of the travelling expenses of selected students living at a distance from the place of lecture. It must be remembered, however, that such classes—as was always the case with specialities—would never be permanently large. In Glasgow, such subjects as "Oils, Paints, and Varnishes," "Bleaching, Dyeing, and Printing," "Fuel," "Iron and Steel," did not command an average attendance of more than about 20. The City and Guilds of London Institute, which had of late years started evening classes all over the country in a great variety of technical subjects (many of them not chemical), reported an average attendance of 22 per class. He mentioned these facts for the benefit of those who supposed that there was a great demand for technical chemical education, or that a great constituency existed ready made for lectures on technical chemistry. He wished to add his opinion that evening work in technical chemistry was not likely to lead to very advanced results. The Institute of Chemistry (of which he was one of the founders) did not recognise certificates obtained by work in evening classes. He was glad indeed to be able to concur with chemical technologists of long experience whom he had consulted that the only training of permanent value was that which was undertaken during the day; that it should be offered especially to those who were destined eventually to become managers, of whatever grade, in chemical works, and that it should be offered while the mind was sufficiently plastic, and yet sufficiently mature, to receive and appreciate it.

The minimum age of the student should be 16 to 18, according to his qualifications, and his time of going through a thorough laboratory course not less than three years, the last year to be devoted exclusively to research. He had always thought it a cruel thing to place in a work a mere boy with a six months' knowledge of analysis. The time came when processes "went wrong," and practical difficulties had to be faced without delay, and the young chemist received an unsought lesson in his deficiencies. The State might well step in there, and by granting a number of scholarships fairly proportioned to the locality, enable the less wealthy students to acquire a more complete education. It would be extremely desirable that some of these scholarships should be the "travelling" kind. The recipients could then witness foreign methods and examine foreign plant *in situ*. At his suggestion the governors of the Glasgow Technical College had accorded that privilege to the holder of the Stenhouse scholarship. Lastly, it must not be forgotten that lectures on technical chemistry required a costly outfit, especially for models. Where these related to a special industry in the district, the district might fairly be called upon to supply them, but models relating to the "great" industries, such as alkali works, dye works, and print works might legitimately be provided at the partial cost of the State.

To sum up,—the constituency for a reception of State aid in technical chemistry was highly important, but not numerically large. While the locality should undoubtedly contribute its best as to buildings and maintenance, the State might reasonably be asked for assistance in the expenses of models, the founding of scholarships, and the provision of a professor.

Mr. G. G. HENDERSON said that Professor Dittmar had expressed his own opinion when he said that the foundation of all technical education in chemistry must be a thorough education in general chemistry. But he would go a little further, for he would include a good knowledge of physics, and he believed that in many cases a knowledge of chemical engineering would be of much use. Until the student has become familiar with the general principles of chemistry and physics he was not fit to begin to specialise on any technical subject. He thought that the State might do much by assisting science colleges at present in existence, and if necessary, founding new colleges, where these subjects might be taught; but the State aid must be given in less miserly fashion than in the past, because unless the lectures were made to some extent independent of fees, these must be too high for many who would otherwise become students. He believed that many technical manufactures could only be learned in a chemical work, but such was not the case for all manufactures, and he therefore agreed with Professor Mill's suggestions so far as concerned these. It would not be difficult to arrange courses of technical lectures suitable to the wants of each district, but it would be rather troublesome to apportion State aid equally.

Mr. T. L. PATTERSON quite sympathised with what Professor Dittmar and Mr. Henderson had said. He would rather that a young man should first study general chemistry thoroughly before going into a chemical works, than that he should devote his whole time to the study of the manufacture of any special article. If a young man had a thorough training in the laboratory in general chemistry and physics, he would soon be able to apply what he had learned in the scientific laboratory, when he went into a work's laboratory, and would consequently be of some use to his employers.

Mr. R. D. PULLAR said he quite agreed with the views that had been put forward by the other speakers. It seemed to him to be scarcely fair to call upon the State to provide any assistance for special subjects, because it was only to a limited number of people any such special training could be of service. It was important, however, that there should be some means provided by the State for as many as possible getting a sound instruction in general chemistry. Of course it would be quite impossible to have classes assisted by the State, if the pupils did not go forward for examination. If there was to be State aid there must be State examination. He was of opinion that for those who could afford the time and money to get special instruction after a course of general chemistry, it was a decided advantage. He considered himself very much benefited by the time he spent at the School of Dyeing in Leeds. It saved him a considerable amount of time when he entered their own works. A great deal was at once more apparent to him, owing to the special instruction he got in the general principles of dyeing, the actions of mordants and colouring matters, and the general properties of fibres.

Dr. J. CLARK said they were all tolerably well agreed that the best way to acquire a technical education was, in the first place, to get a sound ordinary education; secondly, to devote three or four years to the study of science, and thirdly, to devote the rest of the time to the particular manufacture desired. It was not possible to pick up sufficient knowledge of any manufacture so as to be able to practice it profitably, unless in a work where such a manufacture was carried on. And that seemed to him to be the principal objection to the establishment of technical schools, if by the term technical school was understood, a school where a student was expected to learn a particular business sufficiently well to be able to go out and start to work that business. At the same time he would not go so far as Professor Dittmar and say that aid should not be given to some sort of technical education. He saw no reason why there should not be established a lectureship, where a general survey of all the principal manufactures might be had. But the subject under discussion was not as to the method of technical education, but what the Government should really do to assist technical education. The sons of the "masses" were not able to spare the time and money to get a general education and also a specific scientific education; hence, if the Government were to do anything it should be to facilitate the education of these, who were not able to spare either the time or money themselves. The first way in which the Government might be of use in the spread of technical education was in the providing of secondary schools. There were plenty of primary schools at present, but very few secondary ones. In addition to that he saw no reason why the Government should not assist in transferring the most advanced pupils in evening schools to technical colleges, where they could learn more science than it was possible for them to get in the evening schools.

Mr. D. WILSON, jun., quite agreed with Professor Dittmar in all that he said, except in regard to his own trade. He thought the trade of agriculture was quite a technical one, and that a three years' course of study in chemistry was not required for ordinary students, but that the Government might do something in the way of aiding travelling lectureships.

Dr. J. M. MILNE said that in reference to the Government grants for students who passed the examination, he thought the evil of that system was only beginning to come out now. Payment by results was faulty. Such a system could not lead to anything else than cramming. On the part of teachers it simply meant a matter of pounds, shillings, and pence. The money spent in that way was just wasted, and it might be put to much better purpose, say, for the better endowment of schools and colleges, and in the way of affording facilities for the fitting up and furnishing of laboratories.

Mr. WM. FOULIS said he quite agreed with most of the speakers as to the necessity of a chemist being thoroughly trained, but another view could be taken. It seemed to him there was no branch of chemical industry but what would be the better of technical lectures—lectures not intended for trained chemists only, but for all the men in the work, so that they might have some knowledge of the chemistry with which they were coming into contact every day. This would enable them to become more intelligent workmen.

Mr. C. M. AIKMAN said all must be agreed that before any one could benefit by a course of lectures on technical education, he must first have a thorough grounding in chemistry. He thought that the State might be asked to endow special chairs for the various great industries of the country, such as agriculture, because in so doing, it was benefiting not one class of people only, but was promoting the general prosperity of the country. As an example, he instanced the cultivation of sugar-beet in Germany. Scarcely any subject looked more difficult, at first, than the introduction of that article, but thanks to the thoroughly scientific and liberal way in which the German Government acted, the cultivation of it was now an accomplished fact. Regarding technical education being extended to agriculture, to show that there was a distinct call for that, he pointed out that in the short time the Technical College had devoted to that subject there were over 100 students attending the lectures.

Mr. E. C. C. STANFORD spoke of the difficulty there was in learning applied chemistry. If one looked into any work on that subject, he would see that it was years behind the age. The reason of that was that professors of chemistry could not write these works, and men engaged in the manufactures would not. So he thought State aid was required to build laboratories and larger colleges for the chemical profession and for the people generally, museums, and libraries. Another thing which he might refer to was the great importance of the study of organic chemistry in the present day. He need not point out that it was a study which was not very easily carried out in this country, and he thought the State might do something to make that study more accessible. If there was anything else he would like to have State aid in, it was in the direction of getting rid of examinations.

The following resolution was finally agreed to:—

Resolution.—“That, in the opinion of this meeting, State aid is urgently required to better endow existing colleges, and, where necessary, to establish new colleges for the teaching of chemistry and the allied sciences in the most thorough manner, and at moderate fees, rather than to establish schools for the teaching of special manufactures; and that scholarships should be founded in connexion with the colleges in order to assist deserving students to complete their education.”

PROFESSOR CLOWES IN THE CHAIR.

DISCUSSION ON TECHNICAL EDUCATION IN CHEMISTRY.

MR. C. L. ROTHERA (Vice-Chairman, Nottingham School Board), in introducing the subject for discussion, said it would be well to briefly consider the various forms in which the Government at present rendered aid in technical education, and whether those methods were capable of extension or should be abolished and others substituted. Beginning with the elementary schools there was very little provision in the upper standards for the introduction of technical education under the regulations of the Science and Art Department. A certain amount of Kindergarten instruction was given (which had been exceedingly valuable) in the elementary classes. Beyond that they had the provisions of the Science and Art Department and the science classes of local colleges. Now how far it would be possible for any of those provisions to be extended was the subject for consideration, and his feeling was that the Government might aid in this way: First of all, by having the period of school life and the time of exemption extended for a little longer. At present half-time attendance commenced at 10 years of age, and full time at 13, or on passing the sixth standard. These should be extended further so as to give opportunity for the extensive introduction in upper standards of instruction in technical subjects. The proportion of time devoted now in the upper standards to instruction in science was exceedingly low in proportion to that devoted to mere literary subjects, and greater opportunities might be afforded in this direction by establishing continuation evening schools, where young people of from 14 to 16 years age should be required to attend for one or two of evenings a week. There were various other ways in which technical education could be advanced, but not ways in which the Government could interfere.

Employers, now the system of apprenticing had been abandoned, might give the young people more time for instruction. Grants should not depend upon results. Teachers' remuneration should be secured to them and not depend upon the number of students or the number of passes. It was a well-known fact that educational institutions in principle were never self-supporting, and had it not been for benefactions in the past there would never have been the educational provision there was. It was for the State to supplement and complete the work thus begun. Individuals could not be expected now to maintain the work of technical instruction. What was required was more municipal and more Government grants to institutions of the University College kind, and all such aid would be well bestowed. The Bill introduced by Sir Henry Roscoe was on the whole satisfactory, and seemed to conform very closely to the provisions of the Scotch Bill. It seemed to him that the development that could be hoped for was only upon existing lines by the extension of those lines. By greater liberty and payment of allowances the State could thus aid in the development of opportunities for teaching.

Dr. BOWMAN (Halifax) had given a great deal of attention to the question of technical education, and how it could be best advanced in this country. At the very outset it was necessary to define what was meant by technical education; in his opinion the line should be drawn the moment science was begun to be applied to actual practical industry. At the present time there was sadly too little instruction given in schools of practical science. How could aid be given to men of chemical training to enable them to turn the knowledge they possessed to some of the great industries, which they could not do when encumbered with their every-day employment? Men who had received a good chemical education were often completely at sea when they wanted to apply their knowledge in a practical direction. There should be tacked on to all universities and colleges classes like those of the University of Edinburgh, where there was a special chair of applied chemistry, and where, when sufficiently grounded in pure chemistry, students were taught how to apply it to manufactures. They were also taken to see processes of manufacture, and were pointed out the principles underlying them. There were many young men who would like to pursue their studies a little further, but their means were not sufficient for the purpose: some of these men might make their mark if they had the opportunity. If the Government could see their way it would be a good thing to subsidise such as had shown aptitude by endowing "working scholarships." If young men practically engaged in the scientific part of their special industry could enter a technical class by the aid of such scholarships, that would materially aid technical education. In connexion with the Bradford Technical School some valuable researches had been made on the chemistry of wool dyes by Dr. Knecht, who would have very much liked to carry that work a little further, but he had not time. Several students had assisted him, and would have been the very men to have carried out this work, but they could not afford to do it, and thus technical education suffered. Two of these young men subsidised by Government scholarships for two or three years could have done the work.

Alderman LINDLEY (Chairman, Nottingham University College Committee) was afraid that the

exigencies of every-day life would prevent children being kept at school so long as Mr. Rothera asked. He also thought Mr. Rothera would find great difficulty in making young people of 14 to 16 attend evening schools. To his mind the sooner board schools were made truly national schools in every respect the better, and to the school board should be entrusted the technical education of the country generally. And it was not only in the elementary schools that they must foster this education, it was in secondary schools as well. They would be glad to know that it was the intention of the Government to make grants to local colleges throughout the country, and he hoped that Nottingham University College would receive a proper grant.

He was rather fearful that if they altered the mode of payment in the science and art classes very largely the results would not be so satisfactory. He was in favour of increasing the grant of payment to teachers. When they remembered that payment by results necessitated the co-operation of the students it would not be well to relax that method. It had the effect of making the students feel that out of gratitude to the teacher they must be regular and give attention. He thought the school board should certainly have power to pay the fees for all deserving students who were willing to attend technical classes in the evening, not only classes in their own schools but also at local colleges. By increasing the number of evening students in that way they would greatly advance technical education. He looked with favour upon Sir Henry Roscoe's Bill. What was wanted was to strengthen the hands of the school board and to encourage the scholars by the payment of fees.

MR. JOHN R. ASHWELL (Hon. Secretary, Nottingham Section) had not had the opportunity of studying the provisions of the late Bills in detail, and would therefore confine his remarks rather to the consideration of the question "In what direction is State aid needed to assist technical education in chemistry?"

Sir Henry Roscoe's late Bill dealt with elementary instruction in chemistry and other subjects as the basis for any more advanced instruction hereafter. The late Bill seemed rather scientific than technical so far as chemistry was concerned. He fully agreed with Dr. Bowman that technical instruction was the application of science to industry. If general instruction in chemistry was to be accepted as the starting principle, then the directions in which applied chemistry was required would baffle enumeration. He understood the scope of the Bill was limited to the subjects specified in the Science and Art Directory and to certain subjects of commercial education, but that other subjects agreed upon by the Science and Art Department and the Education Department might be included. To these "other subjects" he attached the utmost importance because they might embrace the strictly technical subjects, such as those examined in by the London and City Guilds Institute for the Advancement of Technical Education, *e.g.*, brewing, dyeing, printing, steam and steam engine, &c. Thereby the Bill would provide technical education proper.

Respecting the need for State aid to provide scientific and technical education in chemistry, they had to consider the persons taught, the teachers, and the subjects taught.

First. As to the persons taught, he contended that, in the case of children of school age, their chemical education should begin very early in their school

life by object lessons upon subjects with which children in public elementary schools had some slight every-day knowledge. Also that the instruction should be progressive (*i.e.*, from standard to standard) by much slower and easier stages than at present. He would wish to see these elementary science demonstrations made compulsory at all public elementary schools. State aid would be required in the shape of a liberal scheme of scholarships or as free education to provide means for the continuance at higher grade board schools and elsewhere of the teaching imparted at public elementary schools. No one who had seen the intense interest which children at Nottingham and at a few other board schools took in elementary science demonstrations could ever doubt the existence of elementary scientific sympathies in them, and the ease with which the taste would grow. At higher grade board schools such children ought to be able to obtain more advanced but still somewhat elementary instruction in chemistry and physics. Here the taste for science would become more pronounced. After such higher grade schools State aid would be needed to find means for continuing and still further improving the chemical education, say at university colleges and technical schools, where the students ought to have the best possible teaching and facilities, and the widest choice as to the particular phase of a science which they would wish to study, and here, too, they ought to be encouraged to specialise technically as well as chemically, and encouraged by means of State aid. Thus highly trained chemists of the purely academic type and of the technical type would be produced. The university scholarships to which Dr. Bowman had referred would form an important phase when the chemical education of students at university colleges and technical schools needed continuing to the highest point. But without scholarships our universities might do very much by allowing students or others to be examined in one or more of the science subjects of their examinations. The value of this would be very great in the interests of technology, where a man's knowledge of a special science, or of one or two sciences, was all important. Such a scheme of national education, not only in chemistry but in science, would naturally lead to a development of the special gifts of the children of school age. With regard to children at secondary schools, such as those of the high school type, he would wish to see some similar system carried out, but adapting the State aid to be afforded to the special requirements of those schools. He thought that the chemical teaching in these schools needed vastly improving in quality. Quite distinct from children of school age, there existed large numbers of ordinary workmen, foremen, and future masters; and in any provision for advancing technical education, these persons needed providing for upon an entirely distinct footing. He thought the main difficulties in technical classes—*viz.*, small attendance and poor results—arose from trying to mix boys and men in the same class, and especially when of different social status. Not a few workmen attended evening technical and science classes, knowing that if their foremen or masters heard of it, so much the worse would the daily work become for such workman. Indifference and lack of education, as well as lack of suitable teachers and facilities, were among the important reasons why so few ordinary workmen attended evening classes. State aid was needed to provide classes, teachers, and facilities for ordinary workmen—facilities of time, place, and expense. With foremen and future masters the need was far

greater. These very largely, and in the immediate future, would have control and guidance of workmen; and they exerted a very powerful influence on the commercial position of England in chemical technology. He would advocate a similar system to that suggested for children of school age, *viz.*, a system providing the greatest facilities, a progressive system, and at the entire expense of the State. Such a system would need to be carried out by day and evening classes.

Next, as to teachers, the teaching qualification should be raised much higher. Where payments by results, as in Science and Art Department and other examinations were in force, the maximum grant to a teacher should be for any single student, the grant earned for the highest grade at which the teacher had passed in that subject. And that where the teacher's qualification was not obtained by examination, there *very* much more stringent inquiries and regulations should be in force. With respect to teachers of technical subjects, he urged the necessity for compulsory examinations in practical work, and not merely written examinations. It was most important that teachers in any technical school should have been educated among external surroundings very similar to those existing in that particular locality, *e.g.*, a chemist educated in Birmingham, with its entourage of metallurgy, pottery, and other chemical manufactures, and then transplanted to a town with very large textile trades (such as Nottingham or Leicester), was placed in a most unfortunate position for himself and for his scholars. His sympathies, illustrations, and whole bent were out of harmony with the needs of the locality. The scholar, too, needed to specialise early, with a view to his business, otherwise he would find that a large amount of valuable time had, for his purposes, been misapplied.

Third. As to subjects taught. Technically there was the greatest need that the subjects taught should be adapted to requirements of special localities and by men practically acquainted with these special needs, *e.g.*, take the wool-dyeing syllabus or the cotton-dyeing syllabus of the London and City Guilds examination for advancement of technical education. Both syllabuses might be or might not be admirably adapted for dyeing purposes in Yorkshire or in Lancashire, but both quite unsuited for Nottingham dyeing trades. It was a frequent occurrence for the lecturer on dyeing at the City Guilds class at Nottingham University College to have to inform his students that he had to lecture on a subject of no interest whatever to Nottingham dyers, and that while he regretted it, he was most unfortunately obliged to conform to regulations laid down by a central authority. Again, he would ask how many of the teachers of dyeing at the technical schools throughout the country were really practical dyers and not mere scientists? He thought that if they were practical men surely it was strange they did not double their salaries promptly by going into commerce. High class teaching must proceed from personal experience, and in technical subjects State aid was sadly needed in order to pay such salaries as would command men practically as well as scientifically acquainted with their special subjects.

Mr. W. J. ABEL (Inspector to the Nottingham School Board) thought that they should consider the general question rather than the details of technical education. What they required to know was by what general means they could best foster technical

education. He thought Dr. Bowman's definition exceptionally good. Technical education should be commenced very low down, and at the very earliest stages they should instruct the students to apply their knowledge. If students were more frequently taught how to apply the education they received, they would be more impressed with their instruction. Government could best aid their various local industries, not by giving encouragement to any particular science, but by making their legislation very general, and giving facilities for the encouragement of technical education in general. They could then leave it to properly constituted local authorities to encourage what subjects they would. The next question was, who were these educational authorities to be? There were educational authorities who were incompetent to touch upon these subjects. He thought school boards should be made universal. Small boards who possessed no school buildings should be combined into school boards for large districts in sparsely populated parts of the country, so as to induce more competent men to go on the boards. He thought they should direct their efforts to the following ends:—To make large school boards universal, in order to encourage good men; to impress the central authority with the necessity of avoiding detail, and generalising legislation as much as possible; to arrange continuation courses, and to establish especially "working scholarships," the comparative absence of which throughout the country had tended very largely to make English manufacturers fall behind those on the Continent. They wanted more means for carrying on that practical work, that research without which they could not make advances such as were being made on the Continent. Mr. Ashwell had spoken about the specialisation of teaching. He doubted whether they should specialise from the beginning, for there was truth in the old saying that "man should know a little of everything, and all about one thing." Alderman Lindsey was quite right when he said payment by results could not be done away with. They did not want to abolish it, but wanted payment by genuine and not sham results, as was at present the case.

Mr. J. B. COLEMAN (Assistant Lecturer on Chemistry, &c., Nottingham University College) had noticed no provision in the Bill for advanced education, and thought there was to be no grant to colleges from the department unless it was understood by the word "school or college." He noticed in section 3 that there was a grant to be given by local authority or school board for payment of fees and also scholarships. What they desired was that there should be some central authority to concrete the teaching so that less people should teach the same thing twice over. He also recommended a graduated course, starting from the elementary schools. The purposes of the grant, he took it, would be to increase the teachers or to improve the teaching power—to give assistance by grants of apparatus and models, particularly in connexion with technical classes, to pay the fees of deserving students, and also to found additional scholarships.

Mr. F. S. GRANGER (Hon. Local Secretary of Society for Advancement of Technical Education) was under the impression that Sir Henry Roscoe's Bill dealt with higher education. The Bill before them dealt simply with elementary instruction. He himself had certainly contemplated an Elementary Education Bill separate and apart from that for higher technical education.

Mr. LLOYD WHITELEY (Lecturer on Dyeing, &c., Nottingham University College): He did not want to work elementary education under cast iron rules. The Science and Art Department should give grants just as the London City Guilds did. They were too much circumscribed in their teaching. He agreed with Mr. Ashwell, who knew as well as he, what the Nottingham University College did, and that although they could earn grants from City Guilds, they could very imperfectly adapt themselves to the requirements of the trade of the town. They were fixed with an examiner who had, he believed, a thorough acquaintance with some processes of dyeing, but had no acquaintance with dyeing as practised in Nottingham. He, himself, had to teach dyeing as required by the City Guilds, but this was of very little use to Nottingham men. If they were to launch out and teach those phases of dyeing required by the district, their students who went in for the City Guilds examination would suffer. Dr. Bowman's scheme helped every man who wanted to specialise to study equally the teachings of pure science, or of science applied either generally or to specific industries. In cases of this sort, local committees of competent men might be appointed to supervise the teaching and examinations in special or local subjects, and those who knew the needs of the district would be the best men to perform this office.

Mr. KITSON (Science Demonstrator to the Nottingham School Board) thought that a large amount of scientific knowledge should be given to children in ordinary elementary schools, and that a certain amount of it should be compulsory. If they wished to add to this, his two suggestions were, continuation schools or colleges, and classes similar to those held in the City and Guilds of London Institute. He would give a certain amount of scientific instruction in the upper schools (Standards IV. or V.). School boards should be given power either to provide scholarships for deserving children in their schools or to have some of the best children picked out and sent to higher schools where it would not be compulsory to give elementary education. They could not, however, establish higher schools unless they provided for the third standard. This condition should be abandoned and continuation schools for Standard VII. and upwards fostered for giving higher education in board schools. Elementary and advanced education should be kept quite apart; one Bill should not include the two, as there would be some danger of one swamping the other. All who had the interests of technical education at heart would rather see the elementary provided first and then the advanced than have the two together in one Bill and so endanger both. The scheme of the higher schools should be elastic, and subjects taught should have some bearing on the trade of the district. By working or travelling scholarships students might visit other schools and see the methods employed there, and thus supplement the science instruction received at home.

A VISITOR thought that there should also be scholarships for students who were connected with some place of business. The continual adoption of new methods made it very desirable that there should be more touch between the works and the teaching of the college.

Mr. E. FRANCIS (Head Master, People's College, Nottingham): With regard to the provision of funds and granting of power, there could not be two

opinions that the local authority should be the school board. They could not very well separate the teaching in the elementary schools from higher teaching; they were too intimately connected. In order to get higher teaching he agreed with Mr. Kitson that they should begin pretty low down. Continuation might then be made in the colleges which were already provided. They had schools and a great number of colleges, and they wanted power to raise more funds, so as to provide apparatus, teaching power, and all that was necessary to carry on the work. He strongly supported Sir H. Roscoe's Bill, which he thought a very fair Bill. He did not think Mr. Coleman need be afraid of colleges being left out in the cold; provision was made in the Bill for colleges of that kind.

He would like to say a word as to the Science and Art Department and their list of subjects. As a rule they tried to make the subjects as general as possible so as to cover all trades and manufactures, but something more was wanted. The local authority must be entrusted with powers to arrange the curriculum to suit the district. The Science and Art Department could not arrange their syllabus to suit all districts. For instance, in dyeing, a syllabus suitable for Yorkshire would not do for Nottingham.

He thought boys ought to be permitted to extend their education in colleges free of all cost; scholarships would not be necessary if they were allowed to come to colleges free and their books found free. They ought to adopt something of the German system and compel partial attendance at certain schools after commencing work. Boys who went to work very early in the morning were too tired to undertake study in the evening. To a very large extent they were lacking in students in the Nottingham College simply because boys had not time to come. The Bill should have a clause inserted by which boys ought to leave work at a certain time; part of the afternoon instead of being spent at continuation schools or colleges, two or three days a week, also free of cost.

Mr. S. J. PENTECOST thought that in any rearrangement of payment more money should be paid in respect of practical work. The examinations conducted by the Science and Art Department enabled a man possessing the power of composition generally to manage a first class. That was not what was wanted; they should require proof that the work done was practical work. They ought to do away with the present literary examination. If this Bill passed, would the school board have courage to supply the colleges with the necessary funds? Technical education would, no doubt, be exceedingly costly, and, if the school board applied to the ratepayers for so many thousand pounds for this particular work, the ratepayers would kick. He thought the difficulty might be got over to some extent by arranging for school boards to have a large subsidy from the national Exchequer. The British ratepayer did not mind money being paid out of the general Exchequer, and paid taxes more readily than rates, so, if a board, say in proportion to the population in the district, had power to take a lump sum from the Exchequer, increased to some extent by contribution from rates, there would be less difficulty and less friction.

REPORT ON THE WORK DONE BY THE LIVERPOOL ASSOCIATION FOR THE PROMOTION OF TECHNICAL EDUCATION.

BY J. CAMPBELL BROWN, D.S.C.

It will be remembered that in the winter of 1887 an Association was formed in Liverpool for the promotion of technical education, to which this and other Societies were invited to send delegates. These delegates formed a provisional committee, which met and drew up a draft of the constitution of the Association, which has been adopted, with the Earl of Derby as President, and the Mayor of Liverpool and Mr. E. K. Muspratt amongst the Vice-Presidents. The Chairman is Sir James Poole. The Secretaries are Mr. Reginald Bushell and my very energetic colleague, Professor Hele Shaw. The Treasurer is Mr. T. F. Harrison. The various delegates are members of the first Council. The office is at 15, Sweeting, Liverpool.

The activity of this Association is directed to the promotion of efficient teaching of drawing and elementary science, and of manual instruction in the use of tools, in all elementary schools; to the promotion of technical education in continuation and evening schools, and of special classes for teachers; to the enlistment of the sympathy and support of merchants, manufacturers, and all engaged in commercial and industrial pursuits; and to watch legislation.

The Association has requested each of the delegates to report to the Society sending him what has been done. To save time a report has been sent by the Secretary to each member of the Liverpool Section of our Society.

Reports have been made on the proposed Government Bill, amongst other subjects, and although the Bill was withdrawn, the Association resolved to do something practical this winter.

A scheme of instruction in fret-work and wood-working was prepared for scholars in the sixth and seventh standards of elementary schools. And it has been arranged for the present winter to have ten centres in the city, and on each day, for five days of

the week, to hold two classes, each at a different centre, making 100 classes in all, teaching about 40 boys in each class, or 400 boys. These classes are now commencing. Two classes, of 25 elementary school teachers each, are already held once a week, to train teachers for more extended work in future years.

For girls it is proposed to aid the introduction of laundry work into schools, and to extend the teaching of cookery. A limited number of scholarships, of thirty shillings each, are offered for cookery in elementary schools, and these scholars are to receive further instruction at the Liverpool School of Cookery.

The building of the working sheds in connexion with the Walker engineering laboratories of University College was hurried to completion in advance of the rest of the building, and these have been open since October last for wood-working classes for elementary teachers. It is possible that before long classes for apprentices may also be held in the same workshops, in accordance with the wish expressed by Sir Andrew Walker in presenting his Jubilee gift, that it should be made useful to artisans as well as to college students.

Arrangements are being made by the Association for offering prizes or scholarships in some form to apprentices, and to evening class students for work done, to enable them to pass to a higher grade of instruction.

This is a very good beginning to the work of the Association, even in the absence of legislation, and I shall only further point out that to carry on this work and extend it the Association requires members and some money.

The members are:—

- (a.) Governors, all who give a donation of 50l.
- (b.) Life members, who give a donation of 10l.
- (c.) Ordinary members, subscribing 10s. 6d. per annum.
- (d.) Associates, who subscribe 2s. 6d. per annum.

I trust that most of the members of this Society will become members of the Association in one or other of these ways, and enable the Association to show an example to the rest of England of practical work accomplished, just as the Liverpool School Board and the Liverpool School of Cookery have done in their respective departments.

*Meeting held Wednesday, 1st May 1889, at
University College, Brownlow Street.*

DR. HURTER IN THE CHAIR.

A METHOD FOR PURIFYING LEBLANC BLACK-ASH AND THE PRODUCTION OF AMMONIA FROM ITS IMPURITIES.

BY J. L. HAWLICZEK.

It is a well-known fact that certain impurities existing in ordinary black-ash are most objectionable and troublesome in the further treatment of the

"vat-liquor" obtained therefrom, both for the manufacture of caustic soda and especially for the production of soda-ash of good quality and colour. These impurities, to which I shall direct attention to-night, are the cyanogen-compounds, found in black-ash as cyanide, eventually in the liquors as ferrocyanide, sulphocyanide, and cyanate of sodium, together with sulphide of sodium. The first-mentioned compounds, which may be termed in general—the cyanides—and which will be the main object of my paper, are formed during the "balling" process in the revolver or hand furnace from the nitrogenous matter existing originally in the mixing fuel. We shall see presently that these compounds may advantageously be increased in the black-ash by using mixing fuel which contains a higher percentage of nitrogenous matter. The other compounds—the sulphides—will only be dealt with incidentally.

About 10 years ago several eminent chemists, in order to compete with the excellent products of the ammonia-soda process, endeavoured to improve the Leblanc soda-ash in quality and colour. As it was generally admitted that the small amount of iron combined as ferrocyanide in the vat-liquor was, to a great extent, the actual colouring agent in Leblanc soda-ash, attention was chiefly directed to destroy either in the black-ash the cyanide, or in the vat-liquor the ferrocyanide. Without going into the description of the numerous processes and their advantages which had been proposed at that time for this purpose, I just remind you of the able researches made by Peehiney, Walter Weldon, Mactear, Dr. Hurter, and others dealing with the question of the entire destruction of the ferrocyanide in the Leblanc black-ash and vat-liquor.

A first attempt not only to expel but to utilise the cyanogen-compounds in black-ash as a marketable product, *i.e.*, as ammonia or sulphate of ammonia, forms the subject of the English Patent No. 5456 of 1886, granted to T. T. Mathieson and J. Hawliczek, and I have the honour to lay before the members of this Section of the Society of Chemical Industry some of the results so far obtained.

Our method of treating the black-ash is based on the following facts. If a ferrocyanide, cyanate, or sulphocyanide of an alkali is treated with steam at a temperature not exceeding the temperature of dissociation of ammonia, the cyanogen-compounds are split up into ammonia, which passes off in a gaseous state, and leaves behind the corresponding quantity of the alkali as carbonate. The following equation shows the chemical changes which take place by this treatment:—

This reaction is quantitative if the temperature is kept within 680° to 780° F., a fact which I have proved repeatedly by treating pure ferrocyanide of potassium at that temperature with steam, when I always obtained the theoretical quantity of ammonia and carbonate of potash. The same result will be obtained by treating black-ash containing cyanide, or any cyanogen-compound, under similar condition and temperature, with steam or superheated steam. The ammonia resulting from this decomposition is carried off with the excess of steam, and may be condensed by usual means to ammoniacal liquor or used directly for the manufacture of sulphate of ammonia. The black-ash which remains after this

treatment is free from cyanogen-compounds, and has not been chemically changed in any way as regards the alkali. This is supported by many assays of black-ash before and after treatment with them.

After these few words on the principle employed in our method, I proceed to describe the conditions of the black-ash and the method of operating necessary for the successful working of the process on a manufacturing scale. For the purpose of treating the black-ash with steam or superheated steam, we make use principally of the sensitive heat retained in the black-ash after being drawn from the revolver. We allow the black-ash to cool in the bogies until it sets sufficiently to allow the balls to be broken into small lumps, the size of which varies, according to the density of the black-ash, from about 3 in. to 5 in. in diameter. The breaking may be commenced about one hour or one hour and a half after the charge is drawn. The central part of the balls should not be semifused. This point was overlooked in a series of experiments made on a large scale at Messrs. N. Mathieson and Co.'s works, and consequently irregular results were obtained, shown in Table No. 2, which I shall examine more closely further on. On account of our insufficient breaker arrangements, we found it necessary to reduce the

black-ash balls in thickness to about 8 in. or 10 in., but I believe that with proper plant for mechanically breaking—such plant as I shall describe—there would be no necessity for such a reduction in the thickness of the black-ash balls.

Another point to be considered is the physical condition of the black-ash itself. It will readily be understood, if solid black-ash has to be treated with a gaseous matter (in our case, steam), that the success of such treatment will depend mainly on the physical character of the solid material, which, if in large pieces, must be very open or porous, to permit a perfect diffusion of the gases through the solid, otherwise the solid material (black-ash) must be reduced to such small lumps as to expose a very large surface to the steam if the reaction is to be complete. As both these conditions of black-ash now and then occur, we provide ready means to regulate the size of the lumps of black-ash of each individual charge, according to its density, and with a little experience very regular results regarding the yield of ammonia, respectively the decomposition of the cyanides, may thus be secured.

I now come to the description of the apparatus proposed for the treatment of black-ash with steam on a practical working scale. The apparatus which

you see on the diagram here has been somewhat altered from that shown in the patent specification. It is more closely representing the appliances used in the experiments which have been made at Messrs. W. Gossage and Son's soap-works. I feel myself greatly indebted to that firm, and beg to acknowledge at this place the valuable assistance which Mr. F. H. Gossage kindly has given to me in my experiments on this process at his establishment, and which has greatly added to the success. The apparatus consists—

1st, of the mechanical arrangement for breaking the black-ash balls into convenient sized lumps.

2nd, of an elevator for charging the decomposing vessels.

3rd, of the decomposing vessels, and

4th, of the condensing apparatus for collecting the ammoniacal liquor, which can be arranged in any convenient way and which consequently is not shown on the diagram.

The mechanical appliance for breaking the black-ash consists of an ordinary type of stonebreaker B, large enough to receive one ball at a time. The pieces of black-ash leaving this breaker have to pass through an ordinary toothed roller breaker E, which is readily adjustable for the purpose of varying the sizes of lumps. These are now conveyed to the decomposing vessels by the elevator D, for which shoots L are provided for alternative charging. The decomposing vessels A are made of wrought iron. There are three of them, sufficient for an output of about 250 tons of salt cake per week. The decomposers are provided with charging holes and lids M on the top, and discharging apertures and lids at the bottom, which during the time of treatment have to be hermetically closed. Pipes G are shown on sketch for the admittance of steam from the superheater leading in at the top; and the escape pipes H on the bottom of the decomposers for the conveyance of the ammoniacal vapour and excess steam to the condensing vessels. There are also arrangements, not indicated in the diagram, to work the decomposers in sets of two or three at a time for the purpose of readily obtaining strong ammoniacal liquor, containing from 10—15 per cent. pure ammonia. The decomposers are surrounded by brickwork and placed in an elevated position, supported by cast-iron columns for simplifying the discharging of the treated black ash into bogies, which are placed underneath the bottom aperture of the decomposers. The decomposers are placed as near as convenient to the escape flue of the revolver, to make use of the waste heat of the flue-gases for warming the vessels. The temperature of the flue-gases going into the chimney is ordinarily about 600—700° F., and is amply sufficient for our purpose, and by no means injurious to the iron plates of the decomposers. However, independent in and outlet flues are provided for each decomposer, so as to be able to regulate the surrounding heat, and to prevent it becoming excessive. Thus the wear and tear on the apparatus can only be very slight.

With reference to the labour required for working this process, we found that only two extra men are necessary for attending to the treatment of the black-ash, one for the day and the other during night. The operation of dipping, breaking, and discharging the vessel (which, as you have seen before, simply means opening the discharging lid, when the decomposer will empty itself, practically speaking) is attended to by the ordinary staff of revolver-men and vat-setters. As there is no other regular labour required, the expense of working this process is but a very slight one.

The results of the experiments made are classified into two series:—

First.—Experiments made for the treatment of Leblanc black-ash with steam and the recovery of ammonia, resulting from the decomposition of the cyanogen-compounds.

Second.—Experiments made in the revolver for the purpose of increasing the cyanogen-compounds in the black-ash by utilising the nitrogen of the mixing fuel for the production of ferro-cyanide.

A few words on the method of testing black-ash for total cyanogen, respectively ammonia, which has been employed in our analysis and proved to be very regular and satisfactory in its results, may perhaps be of interest.

I have already stated that if any cyanogen-compound is treated with steam within certain limits of temperature, the resulting decomposition into ammonia and a carbonate is quantitative. It will readily be understood that a quantitative determination of these compounds in the form of ammonia may be based on this principle, and this method will be particularly suitable in connexion with our process as it gives a ready means to estimate the amount of ammonia present in the form of total cyanogen in the black-ash and consequently recoverable from it. The results obtained by this test very favourably compare with Dr. Hurter's method of testing the ferrocyanide in the vat-liquor, but, as must be expected, gives a little higher results, owing to the presence of sulphocyanides and cyanates in the black-ash.

The sample of black-ash to be tested is crushed into a coarse powder and 100 grms. of it are placed into an ordinary wrought iron gas-pipe, of, say, $\frac{1}{4}$ in. diameter and 30 in. length. The remaining space on both ends of the pipe is filled with loose asbestos and then stoppered with common corks provided with glass tubes. When charged the pipe is placed into an ordinary gas-combustion furnace and heated to a slight red heat. Steam, which is produced in a common flask, is passed through the heated black-ash, expelling ammonia, which is collected in normal acid. A simple calculation gives directly the percentage of ammonia contained in the black-ash. An assay, if everything necessary is prepared, may be finished in about 15 minutes, and requires very little care and attention.

The first experiments of treating black-ash with steam have been carried out at the works of Messrs. W. Gossage and Sons, in Widnes. The apparatus employed consisted of an upright wrought-iron vessel, large enough to hold a charge of four black-ash balls at a time. This vessel was encased in brickwork, provision being made to heat it from below at the commencement of each operation without overheating it. If, however, several successive operations have been carried out, it was found unnecessary to continue firing, as sufficient heat was retained from the former treatment. Besides, highly superheated steam, which was close at hand, could be used, so that everything desirable was provided for to secure a successful treatment.

Table No. 1 represents the results obtained.

The results of this series of experiments are very satisfactory as regards the regularity of working, the decomposition of the cyanides, and the total recovery of the ammonia. The temperature of the black-ash, as shown by this table, may vary from about 700°—800° F. The superheated steam was also high

In all these experiments the lb. of sulphate of ammonia have actually been weighed, and the treated black-ash analysed for cyanogen.

enough in temperature, from 500°–550° F. If the temperature were to rise much beyond 800° there might, by the reaction of the steam on the cyanide, occur an entire destruction of the ammonia. It might even result in the reverse reaction, that is, a certain amount of cyanide in the black-ash might be reformed, as it is a well-known fact that under certain conditions cyanides can be produced from ammonia. On the other hand, if the temperature is much below that indicated, the cyanides are not acted upon by the steam at all, and consequently remain undecomposed. In this respect not sufficient care was taken in the experiments made at Messrs. N. Mathieson and Co.'s alkali works (recorded in Table 2), the results therefore have been much worse.

In Table No. 1 the decomposition of the cyanides amounts, on an average, from 90 to 95 per cent., in some instances even 100 per cent.; the ammonia recovered therefrom represents the total also, namely, 100 per cent. of the cyanides decomposed. I may state here, that from each individual charge the ammonia has been collected and actually been weighed as sulphate, thus giving a reliable proof of the results obtained by calculation from the cyanides respectively, ammonia in the original and in the treated black-ash. One column in the table gives the time of treating one charge, which on an average is between three and four hours.

The samples of black-ash treated in these experiments contain an unusually small percentage of cyanogen. For instance, in the fourth experiment there were only 0.483 per cent. of ammonia or 7.84 lb. of sulphate of ammonia per charge of three balls. A recovery of 94.5 per cent. of this amount, or 7.41 lb., as sulphate of ammonia, would result in a production of about 80 tons of sulphate of ammonia per annum when 250 tons of salt cake are decomposed per week, or a value (taking the present market price per ton, of 24 per cent., at 12*l.*) of about 800*l.* to 900*l.*

The numerous assays of the treated black-ash show that no chemical change in its original composition has taken place, the alkali being present in percentage and chemical condition exactly as in the original black-ash, only the sulphides being reduced by about 30–40 per cent.

The treated black-ash spent very well and somewhat quicker (due to its granular state) in the vats, leaving behind black-ash waste of the same condition as in the ordinary way of working. The vat liquor obtained contains none or only very faint traces of ferrocyanides (determined by colorimetric test), the sulphides are as low as 0.44 on 100 of alkali, which is no doubt an exceedingly favourable result compared with ordinary vat-liquor, which contains about 1.4 to 2.0 on 100 alkali.

Further experiments of treating black-ash were carried out at the works of Messrs. N. Mathieson & Co. on a large scale, the results of which are represented in Table No. 2.

I produce these results solely with the desire to be complete and to give every figure obtained in the course of experiments on the new process favourable or otherwise. These results show great irregularity in working, especially when examining the columns

Per cent ammonia recovered,
" " decomposed, and
" " lost by treatment,
or leakage. A short glance at the columns stating
the temperature prevailing in the decomposer, and

that of the superheated steam during the time of treatment, will tell at once the reason of these variable results. For in this case the most essential circumstance, necessary for the success of the treatment, has not been observed, so that there was not really a chance to secure as satisfactory and regular results as we had obtained in our former experiments, indicated in Table No. 1. There is no need to refer any further into Table No. 2, as Table No. 1 proves beyond doubt in a most satisfactory way that the process described works well, provided of course that the plant and temperatures are sufficient and adequate.

But certain results in Table 2 with regard to the chemical condition of the black-ash before and after treatment with steam, and which have been omitted in Table No. 1, are noteworthy. They demonstrate that no chemical change in respect to the alkali present before and after treatment has taken place. They illustrate at the same time to what extent a reduction of the sulphides in the black-ash has been effected.

Considering the fact that the cyanides in the black-ash, formerly so inconvenient, now become a product of value, it is desirable to increase these compounds in the black-ash, and, if possible, to utilise the entire nitrogen of the mixing fuel in form of cyanides in the black-ash, and to use mixing fuel which contains a high percentage of nitrogen. (Such fuel can be readily obtained from neighbouring collieries without further expense.) With this increase of cyanides in view, subsequent experiments were undertaken, but have not yet been brought to completeness. Nevertheless, I am able to give certain directions and figures which will prove useful to anyone desirous of making investigations on this subject.

With regard to the theory of formation of cyanides in the black-ash, I have to point out two facts which are contrary to researches made some 10 or 12 years ago.

Firstly. It now is generally accepted as fact by chemists, that the formation of cyanides in the black-ash is due to the presence of nitrogenous matter in the mixing fuel, and not to the action of the nitrogen in the combustion or flue gases on the highly heated alkali in presence of carbonaceous matter, which was the old theory. Therefore, we may reasonably suppose that mixing fuel high in nitrogen should yield a larger amount of cyanides in the black-ash, provided that the condition of working the revolver is favourable to the formation of these compounds.

Secondly. Formerly it was believed that a very high temperature in the revolver was favourable to the formation of cyanides; but, according to our experiments, we find the cyanides are greatly increased if the revolver is worked at a comparatively low temperature. In one instance we obtained black-ash containing 92 per cent. of the nitrogenous matter in the mixing fuel as cyanides. If such a result could be regularly obtained with mixing fuel of about 1.5 per cent. of nitrogen, it would mean the very considerable production of about 370 tons of sulphate of ammonia per annum, with a decomposition of 250 tons of salt-cake per week.

Many experiments have been made for the purpose of increasing the cyanides in the black-ash principally by altering the proportions of the black-ash mixings, at the same time using mixing fuel of a high percentage of nitrogen; otherwise the revolver was worked in the ordinary way. Table No. 3 gives the results:—

The figures in this table, which are of interest, refer to the different black-ash mixings with and without the addition of mud-lime to the sulphate of ammonia available in mixing slack, to the sulphate of ammonia found in the black-ash, to the per cent. of ammonia recovered from slack, and the last column represents the tons of sulphate of ammonia which would be produced per annum from the cyanides in black-ash, with reference to the results obtained in each experiment. Take, for instance, those in the charges Nos. II. to VI., where we find that the mixings have been altered in each case with regard to the quantity of limestone used. In three cases an addition of mud-lime has been made instead of limestone, yet the results in percentage of ammonia utilised show so little variation only (from 46—54 per cent.) that we may safely draw the conclusion that these alterations of the mixings are immaterial. I incline more to the belief that better results, *i.e.* an increase of the cyanides, would be obtained by altering the mode of working the revolver as regards the temperature prevailing at the time of reaction. Charge No. XIV. shows that as much as 92.00 per cent. of the nitrogen in the mixing fuel was recovered in the black-ash as cyanides, and this charge has been worked at a lower temperature than the others, having been underfired. I believe that this was the reason of its very satisfactory results. I had no other opportunity to carry on further experiments on this subject, so that I am not in a position to give absolute directions for the best mode of working the revolver in order to obtain the highest possible amount of cyanides in black-ash, but I may draw up in the following what I firmly believe to be the right way:—

First. The use of mixing fuel of a high percentage of nitrogen (the proportion of mixing being immaterial).

Second. The arrangement of so-called after-charges of mixing fuel added in the revolver just

before the time of stiffening. One-third of the total mixing fuel may be used for this purpose without otherwise injuring the black-ash or the time of working.

Third. The revolver must be worked at a comparatively low temperature, especially at the finish, which may be done by simply dropping the damper in the escape flue.

I have now given full particulars of the process in question as far as my present experience will permit, and I trust that these results will have interested at least those members of the Society who are connected with the alkali trade. The results I have given show that the new process is capable not only to destroy completely the cyanides and thus to produce soda of greater purity, but to provide a new considerable revenue from a source, the existence of which was hitherto an inconvenience, *viz.*, from the nitrogen of the mixing fuel. A yearly production of 150 to 200 tons of sulphate of ammonia represents a value of from 1,800*l.* to 2,000*l.*, and this can be readily obtained from a weekly decomposition of 200 to 250 tons of salt-cake.

DISCUSSION.

Dr. HURTER (Chairman) said that Mr. Hawliczek had given them a very clear and concise account of an interesting process for the destruction of the cyanides and the recovery of the ammonia so formed. According to the tables before them the process seemed to be not only advantageous by affording a purer carbonate of soda, but also to some extent at any rate remunerative, in so far as the amount of sulphate of ammonia obtained during the process was so large as to come to a considerable number of shillings per ton of salt-cake—at least two? (Mr. Hawliczek: "Yes.") He had no doubt that a process like that must be exceedingly interesting to the alkali manufacturers, of whom he was glad to see

a number present, and from whom he expected an interesting discussion. He had no doubt Mr. Hawliczek would be able to give them further information on several points—the pecuniary one in particular.

Dr. J. CAMPBELL BROWN asked whether there was any expenditure of fuel at all, or whether the work was entirely done by waste heat?

Mr. E. W. PARNELL said that Mr. Hawliczek had spoken of the advantage of the removal of the cyanide as effecting the quality of soda-ash manufactured from the black-ash liquors. From his own experience he could speak of the importance of this in the manufacture of high-strength caustic, as cyanides in the liquors caused an increased proportion of sulphate and carbonate in the finished caustic, the former being due to the presence of sulphocyanides.

An important point to which he believed Mr. Mr. Hawliczek had not referred was the very great purity of the ammonia thus produced, being of necessity absolutely free from tarry matters.

As regarded the proportion of cyanide produced in the black-ash, he had frequently noticed that this increased as the time of working a black-ash charge increased.

He would also like to ask how the use of the black-ash was regulated to correspond to its density, and whether there was a loss of ammonia during the discharge of the revolver, as one could frequently smell the ammonia during and after the operation.

Mr. E. CAREY understood that the Chairman and Mr. Hawliczek agreed that, on the figures set forth by the latter, the gross money credit to be gained by the process was about 2s. 5d. per ton on the salt-cake employed; but this was based upon a return of 150 tons of sulphate of ammonia per annum on 250 tons salt-cake per week, and the figures showed that in some cases he had obtained ammonia at the rate of 400 tons of sulphate per annum (Mr. Hawliczek: "Yes"); so that 150 tons appeared to be quite a moderate estimate. If the result were to reach this 400, the gross credit would be more than twice 2s. 5d., which seemed very satisfactory. Could Mr. Hawliczek give them any idea of the total cost involved in the process, including repairs? He supposed that the apparatus was not of an expensive character. He would also like to know the kind of pyrometer employed in estimating the temperature.

Mr. W. P. THOMPSON said that he took it for granted that the revolver was heated to such an extent as would dissociate the ammonia in it, and prevent its actual formation within the revolver, and that therefore it was only when the nitrogen of the slack became converted direct into cyanogen-compounds that it was saved at all. Now, under those circumstances, would not there be a very great increase in the amount of cyanogen if they could thoroughly mix the slack and the chemicals before they started by grinding them both together? Of course it would interfere with the working of the revolvers somewhat, but as an actual fact, had Mr. Hawliczek found the finer the slack, and the better the mixing at start, the larger the amount of ammonia he got eventually? He should have thought that that would be the case, because if the slack burned before it became intimately mixed with the alkali, ammoniacal-compounds would be formed, and be dissociated before they were converted into cyanogen-compounds.

Dr. S. HAMBURGER said, he saw among the analyses of slack, Nos. 7, 8, 9, 10, and 11, that the slack contained about 1.93 per cent. of nitrogen calculated as ammonia. He thought these figures rather high for ordinary mixing slack, and should be glad to hear whether the slack was of a special kind. It also struck him that if nitrogenous refuse organic matter be added to the mixing in the revolver, the yield of ammonia might be increased very largely. For instance, nitrogenous matter, such as was used for manufacturing ferrocyanides, might be found suitable. He should like to hear, whether Mr. Hawliczek had made experiments in that direction. The lecturer had also been kind enough to give them the time required for treating the black-ash with steam. He should like to know something about the amount of steam required. Mr. Hawliczek said the liquor contained 11 per cent. of ammonia. How many cubic feet of such ammoniacal liquor were obtained per ton of black-ash treated? (Mr. Hawliczek: "I did not go into that calculation.") If he could give them that information in any other form, it would be just as acceptable.

Mr. W. NORRIS JONES said that Mr. Hawliczek had suggested that in the finishing off of the black-ash, a final amount of fuel should be added to increase the cyanide. Would that not have the effect of increasing the sulphides materially; as when they over-fired black ash, they certainly increased the sulphides? In the analysis of black-ash, the tables gave .30 and upwards of sulphide on 25 of alkali, or about 1.4 per 100 of alkali. To him this seemed rather high, and when worked down would give a bad ash; or the ash would require to be highly fired in order to destroy the sulphides. Sulphides would also be a great trouble in making soap's ash. The temperature in the decomposers was as high as 1,000° F. Was that due to the chemical reaction that went on in the decomposers, and would that have any action on the sulphides present?

Dr. HURTER said he should like to ask Mr. Hawliczek in the first instance as regards Table 2, in which the best result was on January 28th, 79.8 of the ammonia calculated in the black-ash being decomposed, and 77.5 being actually obtained. (Mr. Hawliczek: "That is a mistake in print. Instead of .5 remaining, it should be .2 remaining.") That result was the best in so far that the amount recovered most closely approximated to that decomposed. Now if they compared in the other column of temperatures 1,025 and 372, they saw nothing to account for this best result. The temperature certainly did not seem to account for it, and he should like to ask Mr. Hawliczek whether he could point out any other condition that was more favourable in that particular experiment than in the others in which very often only half of the cyanide decomposed was obtained as ammonia, and in which the temperatures to all appearances were the same, at any rate not very far different.

As regards Table 3, Mr. Hawliczek said that when nitrogen was 1.16 per cent., the amount of sulphate recovered varied from about 39 per cent. to 50 per cent. With an increase of the nitrogen in the mixing fuel, the percentage became 20 to 35 per cent.; but when the nitrogen came to .6, the result jumped up to 92 per cent. This appeared to be an indication that the quantity of nitrogen in the mixing fuel, and the amount of ammonia obtained, had nothing whatever to do with each other. It looked as if there was a tolerably constant quantity

of cyanogen formed independently of the composition of the mixing fuel, and he would like to ask if Mr. Hawliczek had any explanation to give of this peculiarity of that set of figures.

As regards the temperature of decomposition when they treated the cyanide in solution—cyanide of sodium for instance, or even ferrocyanide of sodium under pressure—in his own researches he found he could not decompose them at 350° F., but at 380° he found that they split up without any assistance whatever into formates and ammonia. He did not want to say one word against the equation given by Mr. Hawliczek, which he had no doubt was correct, but he was only wondering whether it was absolutely necessary to have those high temperatures to decompose the cyanides. It appeared to him a peculiar fact that they required a higher temperature than when in solution. The amount of cyanides in the black-ash would seriously affect the prospects of the process. Now he had never been accustomed to calculate the amount of nitrogen contained in black-ash in the form of ammonia, and therefore those figures he could not readily compare with those they had at their own works; but at their own works they seldom got more in the vat-liquors at any rate than 3 of ferrocyanide on 100 Na₂O in the solution, and if he came to calculate the results of the process on that basis he should not be able to find that there would be 2s. 6d. to be gained. It would be a very much smaller amount, and he did not understand the great discrepancy, for he should come to about between 3d. and 6d. as against 2s. 6d., and there was a great discrepancy in that, and it meant that either their two tests did not agree, as Mr. Hawliczek had done him the honour of saying they did, or their own black-ash contained less cyanides than that of Messrs. Gossage and Mathieson; for from their own tests he could only arrive at the value mentioned.

Mr. HAWLICZEK said, replying to Dr. J. Campbell Brown, the process was carried out entirely by the use of waste heat in the decomposer. The steam was superheated in a similar way. The quantity of steam to complete the reaction as well as the necessary excess was so very small that it was scarcely a matter for serious consideration.

With regard to Mr. Parnell's questions, the size of the black-ash to be treated depended mainly on the physical condition of the black-ash. In order to vary the sizes of black-ash according to its density the roller breakers were made readily adjustable to suit the purpose. The sample of treated black-ash before them was entirely free from any cyanogen-compound, but it did not represent the size of the lumps of black-ash necessary for the treatment, as it had been broken up in order to get it into the bottle. In many instances he had treated lumps of black-ash of about 8 or 10 in. and more in diameter which had been found after treatment entirely free from cyanogen.

Referring to the second question about the incidental loss of ammonia during cooling of the black-ash in the bogies, he had made extensive researches in that direction which, however, had led him to the result that the black-ash in a hot state exposed to the action of the air is not at all materially changed, the only reaction which might take place was that cyanate might be formed which eventually would also be obtained as ammonia. The smell of ammonia arising from black-ash balls which Mr. Parnell occasionally noticed was no doubt due to the damp atmosphere, which acted on the cyanides on the surface of the ball, but did not

penetrate to the inner parts, thus amounting only to a very trifling loss of ammonia.

The working of the revolver at a comparatively lower temperature for the purpose of increasing the cyanides in the black-ash did not materially increase the time of working, say about 15 or 20 minutes, over the ordinary time of a charge.

In reply to Mr. E. Carey, he was not in a position to give the exact figure with regard to the cost of repairs involved in the process; but considering the simple apparatus, when sufficient care was taken not to damage the decomposers by overheating, the wear and tear on the apparatus could only be very slight. With regard to the extra labour, he stated before that only two men were required for attending to the treatment. The stripping, breaking, and discharging of the balls was done by the ordinary staff of revolver-men and vat-setters. The pyrometer used for estimating the temperature in the decomposer was quite of an ordinary type as sold by Casartelli in Manchester.

Referring to Mr. W. P. Thompson's question, he said that the revolver experiments in Table No. 3 had not been completed, as, with the exception of experiment No. XIV., they had only been carried out in one direction by varying the mixings of the charges, using mixing fuel of ordinary size, otherwise the condition of working the revolver as regard to heat had been in the usual way. He could not say if the grinding of the raw materials would increase the cyanides in the black-ash, but in all probability would not be of great advantage, and would involve an extra expense in working.

In reply to Dr. S. Hamburger, the mixing slack used in the experiments, Table No. 3, charge Nos. VII. to XI., containing 1.927 per cent. of ammonia, represented by no means a special kind of slack, the price being the ordinary one. He could also give, if desired, the analysis of various kinds of mixing fuel obtained from the Lancashire district containing from 1.17 to 1.9 per cent. of ammonia. The slack used was known as "Queen's Slack." The use of animal substances, such as horn, waste leather, &c. containing a high percentage of nitrogen, to be added to the charge in the revolver, would no doubt increase the cyanides in the black-ash if the price of such materials would allow their use. With regard to the amount of steam used for the treatment of black-ash, he stated before that the quantity of steam used was very slight. He had no notes at hand to give the number of cubic feet of ammoniacal liquor obtained per ton of black-ash treated, but he should say a simple calculation based on above facts would give the amount of liquor which may be obtained.

In reply to Mr. W. N. Jones, the "after-charges" of mixing slack had been used for the purpose of increasing the cyanides in the black-ash; the few experiments made in that direction proved to be very satisfactory, and regularly yielded from 70 to 85 per cent. of the nitrogen in the mixing fuel, as cyanide in the black-ash. The black-ash itself was of ordinary condition as regards alkali and sulphide. The high temperatures prevailing in the decomposers in the experiments of Table No. 2 were caused by charging the vessel with black-ash which had not been sufficiently cool, and consequently caused the irregular results as regards the yield of ammonia; these high temperatures were not due to any chemical reaction. Referring to the action on the sulphide, the analysis of the treated black-ash of Table No. 2 exemplified sufficiently that a temperature of 1,000° F., and even more in presence

of steam, was by no means injurious to the chemical composition of the black-ash.

In reply to Dr. Hurter, who wished to know how the best results in Table No. 2, experiment July 28th, as regard to the ammonia decomposed, 79·3 per cent. and ammonia recovered being 77·5 per cent., had been obtained, considering that the temperature of treatment stated in the other column was 1,025° F., a heat which, as he (Mr. Hawliczek) had stated, would result in the destruction of the ammonia, he might say that the experiments represented in Table No. 2 had not been carried out under his direct control, but in all probability this good result might be explained by assuming that a large excess of steam had been used in this experiment, so that the rapid current of steam had prevented the overheating of the gases, and consequently the destruction of the ammonia; in fact, the whole experiments in this table presented irregularities as regards the decomposition of the cyanides and the yield of ammonia, which beyond doubt had been caused by the irregularity in the steam used. Referring to the results in Table No. 3 respecting the increase of cyanogen-compounds in the black-ash, he had pointed out most distinctly that these experiments had not been completed and needed further investigations. The experiments numbered I. to XIII. had been made only in one direction, and this in regard to variation of the revolver-mixing. From these results he drew the conclusion that varying the mixings did not increase the cyanides in the black-ash, but that did not mean that a mixing fuel high in nitrogen was immaterial for the increase of cyanides in the black-ash, provided that the conditions of working the revolver, which had not yet finally been ascertained, were favourable for their formation. Experiment No. XIV. was the only one where the favourable conditions had more closely been obtained. This charge had been under-fired, *i.e.*, worked at a lower temperature, and he strongly believed that the success of obtaining 92 per cent. of the original nitrogen in the mixing fuel as cyanide in the black-ash had to be attributed to this fact. As regards temperature of treatment with steam, he had proved by many experiments that a ferrocyanide of an alkali or alkaline earth was decomposed by steam at a temperature not much below about 400° C. into ammonia and the corresponding carbonate. This temperature, at the very least, was necessary for the formation of ammonia from cyanides. He had no practical experience of the condition and temperature necessary for the destruction of the ferrocyanide in a liquid state or in an alkaline solution. However, it appeared that the ferrocyanides in solid condition require a much higher temperature for their decomposition than when in solution, but he could not see how this seriously affected the prospect of the process.

Finally Dr. Hurter gave a comparative calculation of the results obtained in their experiments which would represent a saving of about 2s. 5d. per ton of salt-cake decomposed as against a calculation from Dr. Hurter's own results from the amount of ferrocyanide in the vat-liquor resulting in a saving of about 3d. or 5d. per ton of salt-cake. In this calculation he (Dr. Hurter) had overlooked that the quantity of sulphocyanide and cyanate had also to be accounted for, as these compounds represented a certain extra yield of ammonia, and besides this the revolver at Messrs. Gaskell, Deacon, and Co.'s establishment no doubt was worked in a way to prevent as much as possible the formation of cyanides in the black-ash,

otherwise the percentage of ferrocyanide in the vat-liquor could not be as low as 0·3 per cent. on 100 Na₂O as stated. The lowest result in that respect which he could find in many daily assays of vat-liquor was about 0·63 per cent., which would mean, if calculated as ammonia in black-ash, not considering the other cyanogen-compounds, a turn-out of sulphate of ammonia per annum amounting to about 60 tons or 1s. per ton of salt-cake. However, no comparison in respect to the vat-liquor and the ammonia as represented in Table No. 3 of their experiments could be made, and, as stated in the table, the ammonia had actually been weighed.

DR. BAILEY IN THE CHAIR.

ESTIMATION AND OCCURRENCE OF SULPHUR IN COAL.

BY G. H. BAILEY, D.SC., PH.D.

IN many branches of industry it is of considerable importance to employ a coal containing as little sulphur as possible, and several instances have come under my notice in which difficulties were being encountered, and mischief done to manufactured products, arising mainly from the sulphur contained in the coal.

The evaporation of caustic or alkaline liquors in contact with flue gases, certain metallurgical operations, the manufacture of the finer qualities of pottery and terra cotta, &c., are cases in point, and others will readily suggest themselves to those engaged in the chemical industries.

Then, again, in steam raising, a large proportion of the defects in boilers arise from external corrosion, and the most rapid and dangerous cases of this arise directly or indirectly from the sulphuric acid formed during the process of combustion of a coal containing a high percentage of sulphur. It is quite common for a ton of Lancashire coal to contain half a hundred-weight of sulphur, and yet, I suppose, there are few coal users who would care to introduce, wittingly,

half a hundredweight of sulphur under their boilers for every ton of coal consumed, or who think it immaterial whether they burn this or one-third of the amount.

To gas companies it is of interest to know accurately the amount of sulphur and the forms in which it occurs in coal, for it is not only desirable that the coal, other things being equal, should be preferred which will yield a coal gas containing the smallest amount of sulphur, but will also have the sulphur combined in that form in which it can be most readily removed from the gas. And now that producer gas and gaseous fuel of all kinds are largely in demand, it is not to be overlooked that here also sulphur may occur in such quantities as to exert an influence on some of the processes to which they are applied.

Furthermore, the returns which are usually given by coal vendors as to the amount of sulphur in the coal are usually of little value, and mostly illusory, and any published analyses which are accessible afford little more than a very general guide on this point. I have had occasion, in conjunction with my brother, Dr. T. L. Bailey, of University College, Liverpool, for some time past to investigate this subject, and it seemed to me that the results were of sufficient general interest to bring before the notice of this Society. The general course of the work consisted of:—

- (a.) An examination of the various methods in use for determining sulphur in coal.
- (b.) The comparison of the results arrived at by recognised analytical methods, with a series of experiments carried out on the large scale in actual practice.

Methods of determining Sulphur in Coal.

By means of a large number of analyses carried out upon carefully sampled coals, I have made a comparative examination of all the methods of analysis of importance. All the processes commercially applied to the determination of sulphur depend upon the oxidation of the sulphur to sulphuric acid and the estimation of the sulphuric acid as sulphate of baryta, and I do not therefore propose to criticise the various methods in detail, but to state the conclusions which I have arrived at with reference to the conditions under which the oxidation may be most effectively carried out, and the amount of sulphur correctly estimated.

Oxidation by Chlorate or Nitre.

Results invariably too low, unless indeed the oxidation is allowed to proceed very slowly indeed, and even then different samples require to be differently dealt with.

A very serious objection to this method of oxidation as a commercial method is, however, that the results obtained by two analysts are never comparable. So much depends on attention to minutiae, and on niceties of manipulation. Recently Blum (*Zeits. f. Analyt. Chem.* 1888, 415), after an examination of various methods, has advised the use of the following, due, I believe, to Crossley:—1 gm. of the sample is mixed with 16 grms. of sodium chloride, 8 grms. of potassium nitrate, and 4 grms. of sodium carbonate, all perfectly dry. Apart from the risk that pertains to the use of such large amounts of bodies whose freedom from sulphates must be very carefully tested (even 0.01 per cent. of sulphur in the reagents would give an error amounting to 20 per

cent. in the determination of sulphur in an ordinary coal), there is the interference of the presence of large quantities of alkaline salts in the precipitation of barium sulphate, which, under such circumstances, is not only retarded but even incomplete.

The complete precipitation of a tenth of a gm. of barium sulphate from a solution containing 30 grms. of alkaline salts is a very slow process, and is in no case accurate.

The oxidising action of nitre or potassium chlorate is indeed rendered sufficiently gradual by a large admixture of alkaline salts, but only at the sacrifice of accuracy.

Oxidation by Wet Methods.

Crace Calvert's method may be taken as typical of these. He recognised that sulphur existed in two forms in coal, as sulphates, which he proposed to extract by digesting the finely-powdered coal with a strong solution of sodium carbonate, and as sulphur in other forms which he oxidised by means of aqua regia and then estimated separately, his idea being that only the latter portion would appear in the chimney gases. Oxidation by means of aqua regia I have found unpleasant to work, and invariably yielded low results. In other respects Crace Calvert's method will be referred to later on.

Oxidation by Magnesia.

This method, due to Eschka, gave, under all circumstances, constant and trustworthy results, and it labours under none of the disadvantages of other methods. The only reagents required are magnesia, sodium carbonate, and bromine water, and there is no difficulty in obtaining these in a state of purity. Magnesia can indeed be prepared free from sulphate by igniting magnesite, if it cannot be procured. Bromine often contains sulphuric acid, but can be readily purified by washing or re-distillation.

An intimate mixture is made, consisting of two parts, by weight, of magnesia and one part of sodium carbonate. Two grms. of this mixture are stirred in with 1 gm. of the finely-powdered coal or coke, &c. in a platinum crucible. This is then very gently heated over a Bunsen burner, placed, at first, about an inch away from the flame, and the roasting continued at a gradually increasing temperature, but never so as to bring the bottom of the crucible beyond just visible redness.

This operation usually takes about two hours, and it is finished when the whole mass has become quite white or light grey, with no appearance of black specks of undecomposed coal. It is now exhausted with water, and oxidised by means of bromine water by simply warming, it being quite unnecessary to evaporate down to dryness. The sulphur is now wholly present in the form of sulphate, and the solution may be acidulated with hydrochloric acid and precipitated by means of barium chloride, the sulphuric acid being estimated as barium sulphate in the usual way.

If Crace Calvert's method for estimating sulphur in both forms be modified by the substitution of this method of treatment for the oxidation by aqua regia, the results obtained are more reliable and the process is not rendered more complex.

A selection of the results of the analyses is appended to show the character of the error which is likely to arise by the different methods spoken of.

(1.) Samples of coke residues from destructive distillation of oil :—

	By Magnesia Method.		
	A.	B.	C.
	Per Cent. of Sulphur.	Per Cent. of Sulphur.	Per Cent. of Sulphur.
1st determination.....	0.59	0.60	0.84
2nd determination.....	0.54	0.61	0.79
Mean.....	0.565	0.605	0.815

These samples done by another analyst gave by the chlorate method results falling below 0.25 per cent.

(2.) A sample of coal on which three separate determinations were made by the magnesia method gave as results :—

	Per Cent. of Sulphur.
1st determination.....	3.06
2nd determination.....	3.09
3rd determination.....	3.03

and in no case need the divergence between different analyses by this method be greater than is indicated here.

(3.) Comparison of results by different methods :—

	1st Determination.	2nd Determination.	Mean.
Magnesia method.....	2.73	2.71	2.72
Grace Calvert's.....	2.47	1.95	2.21
Concentrated HCl and KClO_3 ...	2.14	..	2.14
Nitre method.....	2.04	..	2.04
Modification of Grace Calvert's..	2.69	2.66	2.675

(4.) Comparison of results for sulphur in both forms by Grace Calvert's method :—

	S extracted by Na_2CO_3 .			Residual Sulphur.		
	(1.)	(2.)	Mean	(1.)	(2.)	Mean.
Grace Calvert's method	0.14	0.12	0.13	2.34	1.83	2.08
Modification of this....	0.11	0.19	0.15	2.58	2.47	2.51
Total sulphur by } MnO method ... }	2.72					

(5.) In a sample in which three separate determinations were made by the modification of Grace Calvert's method :—

	S extracted by Na_2CO_3 .			Residual Sulphur.		
	(1.)	(2.)	(3.)	(1.)	(2.)	(3.)
(1.).....	0.22	0.28	0.22	3.88	3.70	3.86
(2.).....	0.22	0.28	0.22	3.88	3.70	3.86
(3.).....	0.22	0.28	0.22	3.88	3.70	3.86
Mean.....	0.22	0.28	0.22	3.88	3.70	3.86

On examining these numbers, it is seen that, notwithstanding that the experiments were done with due attention to every precaution, relatively large variations are shown between one determination and another, but that Eschka's process is quite reliable and constant and shows all the characters that are to be desired in a commercial analysis.

Comparison of the Data arrived at by Analysis on the Sample with the Results obtained by Actual Consumption of the Coal under Boilers.

The experiments which were done under this head were carried out for me by Messrs. Bryan Donkin and Co., of Bermondsey, whose works are furnished with arrangements for the examination of chimney gases. The idea with which I set out was to learn what portion of the sulphur appeared in the chimney gases and what part remained in the ash, and whether these numbers were actually such as are arrived at by the Grace Calvert method. As it was desirable that an average sample of the chimney gases should be obtained, the aspiration was continued for several hours, that is practically during the whole period of the firing. It might be objected, however, that since no special precautions were taken (beyond following the usual rule in the collection of chimney gases, a manifestly insufficient precaution) that the gases aspirated from the chimney should be representative of the whole gases passing up the chimney, the amount of sulphur could not be correctly deduced from the measurements made.

And this objection is quite valid since the composition of the gases at different points in the cross section of the chimney varies considerably. The variations referred to, however, only occur in the distribution of air and products of combustion, respectively (arising from down draughts, &c.), and the relative amount of carbon to sulphur as indicated by the carbon dioxide and sulphur dioxide in the gases, would not be affected to any appreciable extent by such irregularities of distribution.

For the purpose in question only the relative amount of carbon to sulphur in the chimney gases was required, this being then considered alongside the relative amount of carbon to sulphur in the coal.

The chimney gases were aspirated from the flues (the chimney will not do) through drying tubes, and then through two or three sets of potash bulbs.

The CO_2 and the SO_2 were in this way absorbed, and the increase in weight of the potash bulbs (and the CaCl_2 tube attached to them) gave the amount of these gases in the known volume of chimney gas aspirated.

The factors which were available for estimating and checking the estimation of the carbon and sulphur in the chimney gases were therefore :—

- The total increase in weight of the potash bulbs, representing $\text{CO}_2 + \text{SO}_2$.
- The relation of CO_2 to SO_2 obtained by weighing the BaCO_3 and BaSO_4 precipitated together, and then dissolving out the BaCO_3 and determining the residual BaSO_4 .
- The analysis of samples of the chimney gas drawn from time to time.

If the whole of the sulphur made its appearance in the chimney gases, it is manifest that the relation C:S in the chimney gas should be the same as C:S in the coal, as determined by analysis,

Separate estimations were made of the amount of carbonic oxide, but this was seldom present, as excess of air was always used during the combustion.

Appended are the results from the comparison in this way of three fuels of very diverse character:—

	By Analysis.	On Combustion in Boiler.
<i>Coke Breeze.</i>		
Sulphur washed out by sodium carbonate.....	0.27	..
Residual sulphur	3.81	..
Ash (and clinker).....	19.13	19.6
Sulphur in clinker and ash.....	..	1.1
Relation of C : S in coke breeze....	100 : 6.45	100 : 3.55
<i>Newcastle Coal.</i>		
Sulphur	1.85	..
Ash (and clinker).....	1.82	5.1
Sulphur in ash and clinker.....	..	1.0
Relation of C : S in the coal	100 : 2.2	100 : 1.156
<i>Welsh Coal.</i>		
Sulphur	1.13	..
Ash (and clinker).....	4.80	5.8
Sulphur in ash and clinker.....	..	0.61
Relation of C : S in the coal	100 : 1.35	100 : 0.719

From these numbers it is not difficult to arrive at very definite information as to the distribution of the sulphur after combustion, and a summary of this is added, the numbers indicating percentages of the whole sulphur present in the coal:—

	Coke Breeze.	Welsh Coal.	Newcastle Coal.
Sulphur in clinkers and ash.....	5.4	4.4	4.8
„ chimney gases	55.0	53.2	52.9
Unaccounted for.....	39.6	42.4	42.3

These numbers are calculated from the total sulphur in the coal, and the conclusion is irresistible that the usual assumption to the effect that that existing in the form of sulphates takes no part in the production of the sulphur dioxide in the flues.

A number of determinations made by mixing sulphates with the coals burnt on a small scale supported this.

The sulphates of course remain in the ash and clinker. There is still, therefore, about 40 per cent. of the sulphur to be accounted for, and this must have remained either in the flues or on the boiler

plates or other accessories. It is known that where the circumstances are favourable external corrosion in boiler plates is a most fruitful source of injury, and that a large proportion of the boiler explosions are due directly or indirectly to this external corrosion. But if the amount of sulphuric acid that is being constantly formed is such as is here indicated, the sulphur in coal is indeed a factor that cannot be disregarded in boiler heating.

I may mention, however, that there is a large quantity of this retained by the flue dust, and in samples of flue dust which have been examined as much as 15 to 20 per cent. of sulphur has been found. During the course of the experiments other observations were recorded by Messrs. Bryan Donkin and Co., and as these may prove interesting in themselves, I append the complete statement of the results observed by them.

Results of experiments on a Lancashire boiler with various fuels, 1888. At Messrs. Bryan Donkin and Co.'s works, London:—

During the course of the work several of the samples of coal were subjected to dry distillation, and in some cases very little sulphur came over in the earlier stages of the distillation, whilst with others there was a good deal evolved during the earlier period. Moreover the percentage of sulphur remaining in the coke varied considerably with different coals. Two samples will illustrate what is meant, and these are selected because they were coals of a very similar character in regard to ash, yield of coke, and relation of sulphur as sulphates to sulphur in other forms. The numbers are percentages.

	A.	B.
Sulphur in coal	1.83	1.10
" coke	1.50	1.16
Ash	1.83	3.88
Coke	71.50	68.79

The ash of "A" contained much oxide of iron.

" "B" " very little "

In sample "A" 58 per cent. of the total sulphur in the coal remained in the coke, whereas in "B" nearly 73 per cent. remained in the coke. This, it seems to me, opens out a question of considerable importance in the manufacture of coal gas. Here are two coals, one of which gives off 42 per cent. of the sulphur it contains with the coal gas and volatile products, whilst the other only gives off 27 per cent. in this way.

This question is worthy of a complete investigation, attention being devoted not only to the relative quantities of sulphur in the volatile products of distillation and in the residual coke respectively, but to the form in which the sulphur compounds make their appearance in the gas, whether as the readily removable sulphuretted hydrogen or in other forms which are incompletely removed by the usual methods of purification.

I cannot conclude this paper without drawing attention to a further issue of importance on which some information has been derived in the course of this work. It is known that the calorific power of coal as calculated or determined on the small scale does not agree with trials made on the large scale. There is a deficiency in the latter case of from 5 to 10 per cent. according to the conditions of combustion and the kind of coal used. From observations which I have made, it has appeared that where the excess of air is not greater than a certain minimum quantity, hydrocarbons appear amongst the products of combustion, and that in any case where the firing is irregular there will be phases of the combustion during which they appear.

This is well known. But, as far as I am aware, it has usually been assumed that if a sufficiently large excess of air is present, no hydrocarbons will result. I find, however, that if the excess of air at any period during the combustion becomes large, there is also a tendency for hydrocarbons to pass off unconsumed, and this is especially the case with irregular firing. Now, a quantity of hydrocarbons which could be detected or determined only with very great difficulty under the ordinary methods of gas analysis, would

affect the results of a calorimetric comparison very seriously.

Suppose, for instance, to take an extreme case that 5 per cent. of the total carbon is transformed into, say, ethylene, and escapes combustion, passing off with the chimney gas, and that the amount of air supplied to the furnace is just treble that theoretically necessary, then we should have for every volume of the hydrocarbon over 600 volumes of oxygen and nitrogen, and 60 volumes of carbon dioxide. Even supposing the oxygen and carbon dioxide removed, we have a residue consisting of some CO, 1 volume of hydrocarbon, and about 550 volumes of nitrogen.

The greatest obstacle in the way of making a correct determination of hydrocarbons under such circumstances, is that of ensuring their combustion when mixed with such a large volume of diluent and inert gas by any endiometric method. I have suggested to Messrs. Bryan Donkin and Co. that they might pass the chimney gases through a tube containing cotton-wool, and then through absorbents for the removal of moisture—carbon monoxide, carbon dioxide, sulphur dioxide—finally passing the gas slowly through a combustion tube containing oxide of copper, and then again through calcium chloride and through potash to determine the water (and hence the hydrogen) and the carbon dioxide (and hence the carbon) in any residual hydrocarbons left in the chimney gases. Such an experiment would, of course, be continued some time.

I have not yet heard the results of any experiments which they may have been able to make in this direction, which in any case will occupy considerable time.

DISCUSSION.

Mr. P. HART thought it just possible that a portion of the sulphur compounds passed away in combination with the ammonia or hydrocarbons, as in the case of ordinary gas manufacture. One method which occurred to his mind of estimating the amount of sulphur in coal, was that suggested by Mr. Davis, where he estimates the sulphur in spent oxide by combustion in a gas furnace, absorbing the SO₂ formed in hydrogen peroxide.

Mr. WATSON SMITH said a French chemist (M. Brullé) had just devised a method of determining sulphur in which he used a combustion tube. He had tried Eschka's method, as described in the 1884 edition of Fresenius' work, and confirmed all that Dr. Bailey had said about it; on the whole it was a very accurate method. M. Brullé seemed to take exception to the ordinary methods, especially that of combustion in a crucible, owing to the fact that in this process the combustion was rather too hasty and sulphurous acid was formed. The sulphites were decomposed before they had time to be converted into sulphates. A little accumulation or inequality of mixture, as in the case of a liquid mixture, might readily account for the effect to which he referred. M. Brullé proceeded to give an improved method of his own, in which he proposed to use a long narrow boat of platinum foil, covered with a sliding lid, which had the advantage of holding the whole of the mixture in a thin layer. A little chlorate of potash and nitre was strewn on the top of the mixture and the boat was then introduced into a combustion tube closed at one end. Some of the mixed salts were

placed between the cover and the boat itself; heat was then applied to the combustion tube, and the mixture was carried over from front to back. It was then precipitated, and this gave satisfactory results.

Mr. J. E. HOLGATE said he had used the lime process, as described by Dr. Bailey, regularly for the last eight or nine years for the estimation of sulphur in coke for blast furnace use, and had found it very satisfactory, both as regards the accuracy of the results and the amount of time, care, and attention necessary to obtain results that were trustworthy. The method of working that he adopted was as follows:—He took 1 grm. of the coke, or 2 grms. if the amount of sulphur were expected to be very low, and mixed it with 1 to $1\frac{1}{2}$ times its weight of pure lime. The mixture was placed in a platinum or porcelain dish and made into a paste with water. The spatula used for this purpose was wiped with a scrap of filter paper, which was then added to the dish. It was then dried at a moderate heat and ignited in a muffle at a good red heat until all the carbon was burnt off, which usually took from half an hour to one hour. Spreading it out in a thin layer shortened the time required for ignition. After cooling, it was transferred to a beaker and dissolved in dilute hydrochloric acid, the dish being cleaned out with a little of the acid. The solution was heated to boiling and filtered. Most of the free acid was neutralised with ammonia, and the sulphuric acid precipitated with barium chloride in the usual way. If the presence of sulphites after ignition was feared, a little bromine water might be added previous to or along with the dilute acid, or if it was feared that some of the sulphur might escape absorption by the lime, a little lime might be sprinkled on the mass previous to ignition.

Dr. BAILEY, in reply, said with regard to Mr. Hart's remark as to the possibility of a portion of the sulphur compounds passing away in combination with the ammonia, he thought they must certainly be left behind in the potash. If the sulphur compensated before the point of aspiration was reached, then, of course, that would be one way of accounting for the loss of sulphur. It was worthy of remark that the lime method practically gave the same results as magnesia, namely, about one-third higher than other methods, and it was also very similar. The magnesia presented, however, manifest advantages over the lime. Being a light bulky powder, the oxidation of the coal proceeded at a much lower temperature than in the case of lime, and any magnesium sulphate that resulted was readily dissolved out without the addition of acid, and hence without any risk of loss due to the decomposition of sulphites. The insolubility of the calcium sulphate was, he considered, a serious disadvantage. Apart from these objections he had found the lime process a good one, but it showed no advantages over the magnesia method to compensate for the disadvantages. He had not, as already pointed out in the paper, detailed more than a small portion of the experiments that had been made or the methods that had been examined.

With regard to the precipitation by means of barium chloride, this, in presence of 20 to 30 grms. of alkalis was incomplete, even if allowed to stand several hours, and the volumetric method which had been referred to was, therefore, open to decided objection. He might mention that he had tried to oxidise the sulphur directly by means of barium

chlorate, which could now readily be obtained in a sufficient state of purity, hoping in this way to be able to obtain the sulphuric acid at once in the form of the insoluble barium sulphate. He found, however, that barium chlorate was too violent in its action, and he had not been able to devise any method of diluting it which should be easily managed and yield correct and reliable results.

Meeting held 2nd April 1889.

DR. BAILEY IN THE CHAIR.

NOTES ON DYEWOOD EXTRACTS AND SIMILAR PREPARATIONS.

BY LOUIS SIEBOLD, F.I.C., F.C.S.

DURING the last 10 years there has been an enormous increase in the production of these preparations, and the time will come when their application in dyeing and calico printing will become so general as to completely supersede the employment of the raw materials. The manufacture of these extracts, to be thoroughly successful, requires to be so conducted as to secure the perfect exhaustion of the dyewoods without the slightest destruction or deterioration of the colouring matters contained in them; and though nothing like perfection has been reached in the attainment of these objects, it is certain that the processes of extraction and evaporation now employed by the best makers are a very great improvement on the older methods. Indeed, there is no difficulty nowadays in procuring dyewood extracts of high excellence if the consumer is willing to pay a price for them corresponding to their quality, and knows how to avail himself of the aid of chemical skill to control his purchases. Unfortunately, however, there is so much hankering after cheap articles, and so little care is taken to ascertain their real quality, that every scope is afforded to the malpractices of the adulterator. There are many dye- and print-works in which large quantities of these extracts are used without being subjected to trustworthy tests. Moreover, much of the testing is done by fallacious methods and often by biassed hands. So fallacious, indeed, are some of these tests, that grossly adulterated extracts are often declared superior to the purer ones, the cause of this being the application of an insufficient proportion of mordant in the dyeing or printing trials, and the consequent waste of the excess of colouring matter in the case of the purer preparation. Professional analytical chemists have hitherto given but little attention to these preparations, and the employment of experienced chemists in works is as yet far from general. The testing of dyewood extracts in such a manner as to throw full light on their purity, the quality of raw material from which they are prepared, their exact commercial value, their suitability for special purposes, and the proportion and nature of any adulterants they may contain, is of course a difficult and tedious task, and must be left to the expert who is in possession of authentic specimens prepared by himself of all the different extracts made from every variety and quality of raw materials, and

who combines a thorough knowledge of experimental dyeing and printing with a large experience in the chemical investigation of these preparations. But when the object of the testing is merely careful comparison of the sample in question with an original sample or previous deliveries, the case is much simplified, and comes within the scope of the general chemist or the laboratory attached to works. A few years ago I recommended carefully conducted dyeing trials on woollen cloth mordanted with bichromate of potash as the best and simplest mode adapted to such cases, and my subsequent experience enables me to confirm that observation to the fullest extent. Most of these extracts contain the colouring matter in two states, the developed and the undeveloped, and an oxidising mordant such as bichromate of potash causes the latter as well as the former to enter completely into combination with a metallic base; whereas many of the other mordants, such as alumina or tin compounds, merely take up the developed portion of the colouring matter together with such small and variable proportions of the undeveloped as might undergo oxidation during the process of dyeing. I would therefore suggest dyeing trials with alumina, tin, iron, &c. only as subsidiary tests indicating the suitability of an extract for certain special purposes, while recommending the trial with bichromate of potash as the one giving the best information respecting the actual strength of the extract in relation to the raw material from which it was obtained, and as giving a fair idea of the money value of the sample. Cotton dyeing does not, as a general rule, afford a good means of assaying extracts, as it is generally done under conditions which do not admit of complete exhaustion of the dye-bath, but it might often with advantage be resorted to as an additional trial throwing further light on the degree of oxidation or development of the colouring matter. Printing trials are apt to give fallacious results unless the proportion of mordant is carefully adjusted to the amount of colouring matter present, and several trials with different proportions would be necessary to prevent erroneous conclusions. For the trials with bichromate of potash on wool I would recommend pieces of cloth weighing about 150 grains, and the most suitable proportion of bichromate of potash is 3 per cent. of the weight of the cloth. The requisite number of pieces (equal to the number of samples to be tested) should be thoroughly scoured and then heated in the bichromate solution at or near the boiling point for not less than 1½ hours, after which they should be well washed and then dyed separately in the solutions of equal weights of the extracts at the same temperature and for the same length of time; 15 grains of extract is a suitable quantity for a first trial under these conditions. These trials can then be repeated with different relative proportions of extract in order to ascertain what weight of a sample would give the same depth of colour as 15 grains of the standard example. Many precautions are required both in the mordanting and dyeing processes in order to obtain trustworthy results; and though the trials with bichromate of potash give the most reliable information of any single test, they should be supplemented by the subsidiary tests already alluded to, and also by a chemical examination, in order to obtain a knowledge, not merely of the wood strength, but also of the general nature of the extract. An adulteration with molasses or glucose can be best determined by fermentation in comparison with a pure sample. Mineral adulterants may, of course, be detected by an estimation and analysis of the ash, after making due allowances for variations due

to differences in different kinds of the same dyewoods. The estimation of the individual colouring matters in these extracts by means of a chemical analysis is under all circumstances a task requiring much experience, especially as the colouring principles are associated in different qualities of each class of dyewood with different proportions of other constituents which often give much trouble to the unpractised experimenter. Extracts made from logwood roots are now largely manufactured and often substituted or mixed with the extracts of real logwood, and have in some instances been palmed off as logwood extracts of high quality. The correct determination of such admixtures, like the fixing of anything like the exact commercial value of dyewood extracts, requires nothing less than a complete chemical investigation coupled with numerous dyeing trials in comparison with standard preparations, and should be left to an expert.

The presence in dyewood extracts of colouring matters in various stages of development has hitherto militated against their use in place of the raw materials by many dyers and printers who are still employing inherited and antiquated processes in which the whole of the colouring matter is not rendered available. It is often asserted by these that even the best of extracts fail to give anything like the results attained by the use of well-prepared woods, and that, indeed, their application proves a complete failure. Such, failure, however, is simply due to the want of chemical knowledge on the part of the dyers, for there is no real difficulty in making any good and pure extract serve all the purposes for which the woods were used. It is to be hoped that in this branch of industry, as well as in many others, the employment of chemists will become more general than at present, and not be restricted, as is often the case, to young men without experience and without the trained intellect so essential to success in chemical investigations. High class chemical skill is of course available to the manufacturer, but the man of science who brings matured knowledge and valuable brain work into the business required social as well as pecuniary recognition, and the sooner and more fuller this fact is appreciated the better it will be for the maintenance and progress of our industries.

With regard to the astringent extracts, such as sumac, myrabolan, divi, valonia, quebracho, oak, &c. it is the aim of the manufacturer, whenever such extracts are intended for the purposes of dyeing and printing, to obtain the tannin in a form in which it is best calculated to fix itself upon the fibre. The case is somewhat different when the same extracts are required for tanning. For this purpose it is necessary that the extract shall have considerable permeating power, and that the tannin contained in it shall readily yield leather of the desired texture, colour, and permanency. Extracts specially suited for this purpose are by no means always the most suitable for the dyer and *vice versa*.

A brief description of the processes by which the astringent extracts may be tested with particular reference to their fitness for definite purposes concluded the paper.

A further contribution on this subject was promised.

DISCUSSION.

Mr. WILSON: Mr. Siebold had referred to the action of alumina and tin, but he (Mr. Wilson) knew that most chemists engaged in print-works did not use bichromate of potash—they used alumina

and tin, and just made one single test. Mr. Siebold had pointed out the difference in the colouring matters present, but in a cotton print-works they did not use bichromate of potash. Supposing they tried it on a large scale and obtained a certain result, on a small scale they would get an entirely different result. Every time a fresh extract was tested the procedure would have to be altered in the dye-works.

Mr. WM. THOMSON: Mr. Siebold had pointed out the very complicated nature of these colouring matters and some of the chemical difficulties which had to be met; also that it was necessary to have a chemist of great practical experience in dyeing with these extracts. It seemed to him that the chemist so engaged must be able to prepare them so as to leave them in some degree of oxidation, and in this direction chemistry would have to be resorted to more especially. Mr. Siebold had mentioned that bichromate of potash was used for producing blacks in dyeing wools. He generally understood that bichromate of potash produced blue. Perhaps Mr. Siebold would kindly explain?

Dr. GERLAND thought the members were under a great obligation to Mr. Siebold for having brought this matter forward, and he was specially grateful to him for pointing out the difficulties they had to contend with in estimating the value of these materials. He hoped Mr. Siebold would fulfil his promise and come forward with fuller details on some future occasion. He quite agreed as to the great difficulties to be met with in defining the cause of oxidation. So far they were at a loss how to interrupt oxidation or how to keep it within bounds, and at the present time there was nothing left to them but to take the materials and make the best of them.

Mr. WATSON SMITH wished to know if fractional tests had been applied. If, for instance, a certain number of pieces of wool were weighed and the quantity of extract to be used, measured, would the colours come out uniform, or would they not vary according to the difference in fibre or the difference in the constituents of the solution?

Mr. SIEBOLD, in reply, said: With regard to the question as to whether experimental dyeing with bichromate of potash should be employed as a test even in works where all the dyeing was done with other mordants, he was decidedly of opinion that it should always be resorted to as one of the tests, inasmuch as it was the only simple and expeditious method giving a fair idea of the actual wool strength and money value of the extract. The test should, in such cases, be supplemented by dyeing trials with the mordants used at the works, and, if necessary, also by a chemical analysis. Printing trials were not necessarily bad tests since oxidising was usually added in these where it was necessary, and any undeveloped colouring matter would thus be oxidised during the steaming process; but, as he had stated before, it was essentially necessary in such cases to have a fair idea of the amount of actual colouring matter in the extract and to adjust the proportion of mordant accordingly. Such trials should therefore be preceded by carefully conducted dyeing trials with bichromate of potash. Mr. Thomson had raised the question whether it would not be well for the manufacturer to prepare these extracts in such a manner that they would contain all the colouring matter in one condition only, in order to ensure greater uniformity in their quality and mode of

application. This would, no doubt, be a desirable step to take if the owners of dye- and print-works were more in the habit of availing themselves of the service of competent chemists experienced in this branch, for then they would be able to make any extract do its full work irrespective of the state of development of the colouring matter. Such, however, was not the case, and it was a very common thing for the consumer of dyewood extracts to require the manufacturer to prepare them specially for him so as to suit his own dyeing recipes, or in other words to give exactly the same shades weight for weight by his own method of dyeing as the article he was in the habit of using. The manufacturer was thus often compelled to make many different qualities of the same extract to suit different customers. For the same reason adulterated articles were often preferred to the pure ones. There was, perhaps, no branch of industry in which chemical skill of a high order could be applied with greater advantage than in dyeing, and nowhere was this fact less recognised. Some of the processes of dyeing were exceedingly wasteful and stood in much need of improvement. He (Mr. Siebold) knew a large works in which a ton of logwood extract was used daily for black dyeing only, and he might safely assert that of this enormous quantity only a very small proportion would be fixed on the fibre, while by far the greater proportion was utterly wasted. Such a waste could only be prevented by a searching investigation of its causes by trained skill. Mr. Thomson had further alluded to the colour obtained with logwood or logwood extract and wool mordanted with bichromate of potash, and seemed to be under the impression that the colour thus obtained was not black but blue. This was undoubtedly the case in dyeing trials performed as tests, as these were conducted purposely with a very small proportion of colouring matter in order to admit of a better comparison of the resulting depth of shades. But with larger proportions of logwood the colour obtained was a fine bluish-black, and with the addition of a small proportion of fustic or quercitron bark to the logwood a jet black was readily produced. With regard to Mr. Watson Smith's observation as to fractional dyeing, he (Mr. Siebold) did not regard this method as a suitable trial for ascertaining the strength of an extract, but he admitted it was occasionally very valuable for detecting an admixture of extracts of other dyewoods, such as quercitron bark extract in logwood extract. It was also a good method of ascertaining the speed of dyeing and hence the relative proportion of fully developed colouring matter of an extract. Mr. Siebold concluded by saying that the subject he had dealt with was a very large one which it was impossible to treat in anything like an exhaustive manner in the course of a single paper. He was much obliged to Dr. Gerland for his kind remarks and to the meeting for the manner in which these remarks had been endorsed.

MR. R. R. TATLOCK IN THE CHAIR.

THE VULCANISATION OF INDIA-RUBBER, WITH SPECIAL REFERENCE TO THE USE OF CHLORIDE OF SULPHUR.

BY CHARLES A. FAWSITT, F.R.S.E., F.C.S.

THE vulcanisation of india-rubber is not only a matter of great importance to the rubber manufacturer but also to the public in general, as by the incomplete carrying out of the process goods are produced which are of comparatively little value. For instance, a waterproof coat or tobacco pouch, which gets stiff in cold weather, is a familiar example, and is owing to the goods not being completely vulcanised, or, as is technically termed, "cured."

In an article on the india-rubber exhibits in the Glasgow Exhibition of 1888, by Mr. Anderson Smith, which appeared in the "Glasgow Herald" about the beginning of October 1888, statements were made as regards the durability of vulcanised india-rubber goods which I think were apt to convey an erroneous impression to those without a special knowledge of their manufacture. The following are extracts:—

"Nothing gave such an impetus to the rubber trade since Mackintosh, as the mingling of the crude article with sulphur, so as to make what is now so universally known as vulcanised rubber. But the article is not at all of a lasting character, more especially apparently if carefully stowed away."

Again:—

"In any case vulcanite decays but too readily, and vulcanised rubber loses its elasticity and rots in a comparatively short time."

Of course it depends entirely on what meaning is attached to the terms "lasting character" and "short time," but the impression conveyed to the minds of not a few was that 12 months would be sufficient for

the deterioration of all vulcanised goods. If the process were very imperfectly carried out, no doubt such might be the case, but rubber goods are produced which will stand for a considerable time. I was lately shown samples of vulcanised rubber goods which were exhibited by Messrs. Warne and Co. in the London Exhibition of 1882, and which have since been exhibited in the South Kensington Museum, exposed to sunlight in a glass case, and some of the articles still retain their original elasticity, whilst others which have hardened on the surface are quite soft and pliable immediately below it.

I was also kindly shown some fine "cut thread" by the same firm, and also by Messrs. Moseley and Sons, which was 19 years old in each case, and I may say that that thread will show deterioration far more quickly than thick rubber. The above rubbers were vulcanised either with sulphur or sulphide of antimony without any compounding, as in that case they would be certain to lose their elasticity in a less time.

Another instance of the longevity of vulcanised rubber is furnished by a mat which is being exhibited at present in Glasgow by the North British Rubber Company, and which for 24 years did service at the principal entrance at Messrs. Arthur and Co.'s warehouse. I was informed by one of the principals of the latter firm that at least 30,000,000 people must have passed over this mat, which on examination did not show any sign of deterioration except that it was worn a little in the middle. In fact it seems to confirm the view that india-rubber or gutta-percha will be the pavement of the future.

The above will serve to show that vulcanised rubber does not in all cases deteriorate quickly. Mr. Smith also says that vulcanised rubber deteriorates more quickly if stowed away, which is not always the case. Take a thread, for instance, which, if carefully shut up in a box, may last for 20 years and keep in good condition, but the same thread if exposed to strong sunlight would not last a month.

The substance which is almost entirely used for vulcanising rubber is sulphur, either in the combined or uncombined state, as the latter principally in the form of "flowers of sulphur" and as the former in combination with a metal as a sulphide or with chlorine as chloride of sulphur. It is in connexion with the action of this latter body that this paper treats.

For reasons which will be mentioned further on, the chloride process has not been a favourite with india-rubber manufacturers; in fact, it has mostly been used for certain work which could not be produced without it, for instance those beautiful silk waterproofs so much worn by ladies in the summer months are "cured" by this process, as the heat necessary for "curing" with sulphur or metallic sulphides would be sufficient to injure the silk. In fact, mostly all "transparent" proofing is done by this process whether on wool, cotton, or silk. Being interested in the process, and, from a little experience I had gained, confident that good results could be obtained, I resolved to try and determine the conditions necessary for attaining those ends.

In order to render what follows clearer, it will be advisable to convey to you some idea as to the process now in use for vulcanising with chloride, and at the outset this process differs from the others in that the chloride cannot be mixed with the rubber as in the case of sulphur and sulphides, as it vulcanises at ordinary temperatures, hence it is called the "Cold cure" process, and the rubber could not therefore be kept in the plastic state

necessary for its subsequent manipulation. As an example I shall take that of a waterproof coat. The rubber is first softened with solvent naphtha and then kneaded by a machine into a doughy mass. This is now spread in very thin layers upon the cloth, the solvent naphtha driven off by heat, and the coated cloth passed between two revolving rollers, one of which dips into a solution of chloride in bisulphide of carbon or other diluent, and so the surface of the rubber is wetted as it passes between the rollers. The cloth is next warmed so as to expel the bisulphide and complete the reaction between the chloride and rubber, and which consists in an interchange of sulphur for hydrogen which unites with Cl_2 to form HCl . In some cases the cloth is again passed through the vulcanising mixture.

In order to ensure the complete decomposition of the chloride and neutralise any acid which may have been formed, the cloth is usually exposed to the action of ammonia.

Articles made of cut sheet, such, for instance, as tobacco pouches, are "cured" by dipping them into the solution and afterwards pickling them in a weak solution of caustic soda or other alkali.

On account of the rapid action of chloride of sulphur great care is required in carrying the different processes to a successful issue, and a knowledge of the properties of the chloride is almost indispensable.

As regards the chemicals employed, *i.e.*, bisulphide of carbon and chloride of sulphur, great care should be exercised both in the selecting and testing of the same, as this process has often got into disrepute through the india-rubber manufacturer using in ignorance what was unfitted for his purpose.

In a paper which I read before this Society in 1886, special attention was drawn to the fact that the different chlorides of sulphur occurring in commerce have different compositions and behave very dissimilarly when brought into contact with rubber, and to attempt to produce good work with the same proportions of each kind must result disastrously.

The chloride which appears to be best fitted for general work is one having approximately the composition S_2Cl_2 , as it can be used in much stronger solution than one containing SCl_2 , and at the same time does not act so violently on the rubber. Besides this, it is more economical, as it contains a higher percentage of sulphur, and as it altogether depends on the percentage of this substance taken up it is possible to do more work with it.

As regards the bisulphide of carbon used, it should not contain any free sulphur or oily and tarry matter, nor leave an unpleasant smell behind on the goods. This is accounted for by the sulphide containing a small proportion of some undefinable substances which occur in the crude product, and are difficult to remove if once allowed to creep in.

I conducted a series of experiments in order to find out in what proportion the sulphur was taken up by rubber, using different strengths of solution and varying the treatment, and at the same time to find out how the rubber vulcanised by this process compared with that done by the other methods.

I procured for the experiments some "cut sheet" of good quality (kindly supplied by Messrs. Moseley and Sons). The thicknesses were as follows:—

No. 1.	$\frac{1}{16}$	of an inch =	.4	mm.
No. 2.	$\frac{3}{32}$	"	=	.65 "
No. 3.	$\frac{1}{22}$	"	=	1.1 "

Nos. 2 and 3 being approximately two and three times as thick as No. 1.

The following was the method of procedure for vulcanising and afterwards testing samples in order to find out if they had been properly "cured." A bath of the proper strength having been made up, the rubber, previously softened by heat, was then immersed for a certain time and afterwards transferred to a drying bath. In some cases the rubber was dipped in pure CS_2 before being immersed in vulcanising mixture, and in others was washed with the same reagent after vulcanising. The samples when dry were laid upon a table in a cold room, where they were exposed during the winter months, not only to cold which on several occasions gave a thermometer reading as low as -10°C . (14°F .), but also to a strong draught. They were examined carefully, especially in very cold weather, to see if they remained pliable or if they were suffering any deterioration either on the surface or as to their elasticity. If the samples turned hard on standing they were deemed to be only "*semi-cured*," if they remained pliable and would not tear when stretched as severely as possible with the hands, they were considered "*well-cured*," and if they were soft and pliable, but tore on being stretched, they were called "*well-cured, overdone*." I noticed that some of the samples only turned hard after standing six months. After they had all stood for nine months the sulphur was determined in each sample, and you have the numbers and final condition of the rubber in Table I. The strengths are always stated by volume: for instance, 1 to 30 means in the proportion of 1 gallon of chloride to 30 gallons of CS_2 ; but as the strengths are usually expressed in so many ounces to the gallon by india-rubber manufacturers, it will be as well to mention that—

1 to 60 =	4½ oz.	chloride per 1 gallon CS_2 .
1 " 30 =	9 oz.	" " 1 " "
1 " 15 =	18 oz.	" " 1 " "

It was found difficult to dip exact times, and therefore the results cannot be super-exact, but they will convey a good idea as to how the rubber behaves with solutions of the strengths experimented with.

In Table II. you have a few of the results so arranged that at a glance it can be seen how the percentage of sulphur differs for different times and strengths.

On examining the numbers it will be noticed that the increase in the amount of sulphur taken up by the different thicknesses of rubber for the same time and at similar strengths is as 1:1.8:2.9, *i.e.*, the thinnest rubber (No. 1) takes up 2.9 times, and No. 2, 1.8 times as much sulphur as No. 3 does. Again, for the same thickness of rubber at the same strength, but for different times of dipping, we get the following proportional increase, 1:1.4:2.1, *i.e.*, that by immersing for 30 secs. the rubber takes up 2.1 times, and for 15 secs. 1.4 times as much as at 5 secs.

Again:—

The same thickness of rubber for equal times of dipping in the different strengths of solution gave as the proportional increase 1:1.7:3.9, *i.e.*, the same rubber in a solution of 1 to 15 takes up 3.9, and in 1—30 1.7 times as much sulphur as when dipped for the same time in 1—60, and you will notice that the numbers are almost proportional to the strength, which was in each case doubled.

As regards the rubber which was, previous to vulcanisation, softened with CS_2 , the numbers are higher than with the plain treatment, excepting with

the highest strength and thickest rubber, and I think this must be due to the strong mixture acting so quickly on the surface of the rubber as to render it more or less impermeable.

Experiments Nos. 58—66 inclusive were made in order to see what effect dipping twice in pure CS₂ after vulcanising would have, on removing the surface sulphur, *i.e.* without drying between, and, as you will notice, this was to a large extent removed, for with 1 to 60 there was a loss of, approximately, 28 per cent. of sulphur; 1—30, 36 per cent.; 1—15, 38 per cent.

Dipping only once, experiments 67—73, the loss was respectively 22 per cent., 23 per cent., 28 per cent. of sulphur.

These experiments showed that the sulphur was retained to a great extent on the surface, and could easily be removed.

Experiments 74—78 were made with a view of finding out whether rubber which had been dipped in the vulcanising mixture could be deprived of its sulphur, or, as it is termed, "de-vulcanised," by merely immersing it in pure CS₂, *i.e.* without drying between, and for an immersion of 1 minute it lost 68 per cent. of its sulphur, and the rubber which without this after-treatment would have been

well cured and elastic, was found too inelastic and hard in cold weather.

Experiments 88—93 were somewhat similar to those just mentioned, but with this exception, that the rubber after vulcanising was dried and then treated with pure CS₂ to see if it could be de-vulcanised. The results showed that the drying had a marked effect, as by immersing it for 1 minute in pure CS₂ only 19 per cent. of sulphur was removed, but when it was continued for 5 minutes, 65 per cent. passed into solution. The de-vulcanised rubber was still elastic, but at the same time weaker than without the after treatment, as it tore easily.

The percentage of sulphur for well vulcanised rubber varied 0.7—3 per cent., and the best experiments gave 1.4 per cent. I shall now show you a sample of each thickness of rubber vulcanised from the experience gained in the above experiments.

Thread Experiments.

Along with the "cut sheet" experiments I made a few with some "cut thread" size $\frac{1}{11} \times \frac{1}{11}$ of an inch (2.3 × 1.8 mm.). They were vulcanised in the same manner and allowed to stand for the same time and under similar conditions to pieces of "cut sheet." They were, after standing, subjected to a

breaking test in an apparatus, sketch of which you have in the figure below, and the numbers for which you have in columns 6 and 7 in Table III.

- A. Spring balance.
- B. Clamps for thread.
- C. India-rubber thread.
- D. String joining under clamp to roller E.
- H. Handle for turning roller.
- K. Scale giving length of elongation.

The length of thread taken was 2 inches, but as $\frac{1}{4}$ inch was held in each clamp, only $1\frac{1}{2}$ inches was available for stretching. The thread having been adjusted, the readings of the balance and scale K were taken, the handle of the roller slowly and steadily turned round, the readings being at the same time taken. Three trials were made with each thread.

These numbers bring out very forcibly the great superiority of vulcanised over unvulcanised rubber. Unvulcanised rubber which had been softened by heat, broke with only $\frac{1}{4}$ lb., with an elongation of only 5 ins., but 7 lb. were required for one of the vulcanised samples with an elongation of $13\frac{1}{2}$ ins.

In the same table you will find the percentages of sulphur, method of treatment, and condition of threads in the coldest weather to which they were exposed.

The percentage of sulphur for well vulcanised thread varied from 0.68–1.9 per cent., and averaged

about 1.25 per cent., a number agreeing fairly well with that for the "cut sheet" experiments. The previous treatment with CS_2 had the effect of increasing the percentage of sulphur, and the after treatment with the same reagent had a marked effect on removing the surface sulphur.

The strength of solution most suitable for vulcanising varies with the nature of the process employed as well as the thickness of the rubber and the time during which the rubber is exposed to the action of the chloride.

For vulcanising waterproof cloth the strength will depend principally on the speed of the rollers as well as the thickness of the rubber coating, but in an ordinary way of working the light yellow chloride can be used as strong as 1 to 30, by measure equal in weight to about 9 oz. of chloride to 1 gallon of bisulphide. It should not be used weaker than one-half this strength.

Using the dark chloride 1 to 60 is sufficiently strong, but it cannot well be used weaker than 1 to 100. It will no doubt seem strange that the dark chloride, containing the lesser percentage of sulphur, must be used in a weaker solution, but the reason is, that in strong solutions it attacks the outer surface of the rubber violently and destroys it before the inside is vulcanised. My results apply only to pure rubber, as it must be borne in mind that the mixing of it with foreign material will quite alter the action of the chloride solution. For instance, low class proofing does not contain above 10 per cent. of rubber, the remaining 90 per cent. being made up of substitute and the usual compounding materials. The substitute which seems most applicable for mixing with the rubber is that made by vulcanising rape oil with chloride as it softens, and mixes up very well with "solvent naphtha," and the chloride has little or no effect upon it when the coated cloth is passed through the vulcanising mixture. Besides this it has the property of standing high and low temperatures very well. In fact it often improves the rubber in this respect. The most rational way to vulcanise rubber with chloride appears to be first to soften it with CS_2 , then expose it to the action of the vulcanising mixture, finally dipping quickly in CS_2 ; and if the thickness of the rubber, times of dipping, and strength of solution are properly adjusted, very good results are obtained. Care must be taken in treating with CS_2 that it is not too long continued either previous to or after vulcanisation, as in the former case the rubber will lose a portion of its most valuable, that is, its viscous, constituent, and in the latter the rubber will be de-vulcanised. A short immersion only seems necessary to remove surface chloride and sulphur from undried rubber. For vulcanising articles made of "cut sheet," such as tobacco pouches, surgicals, &c., this process seems specially applicable, and if rightly understood would be more generally taken advantage of. I lately procured some unvulcanised tobacco pouches to see if a good vulcanisation could be effected, as I had often heard that a really reliable pouch could not be obtained by this process. The requirements of a good pouch are elasticity combined with strength, pliability in cold weather, and one not easily affected by heat; durability; and a taking appearance. After a few trials I produced a pouch which answered all these requirements (samples shown). On analysis this pouch gave 1.38 per cent. of sulphur, being less than in any well-vulcanised pouch which is sold.

Now the question arises, has the chloride process any advantage over the others in use? I may safely say it has.

1st. The cost of production is less, as it is possible to turn out a very much larger quantity of material in a given time, say of waterproof cloth, than when vulcanising with dry heat or steam, as the two latter processes are discontinuous, and the apparatus much more costly.

For a low class of proofing the cost does not exceed one farthing per yard, *i.e.*, for chloride, CS_2 , and labour, and for high class not above one half-penny, whilst for the other processes the cost will be double this.

2nd. There is no efflorescence of sulphur, which is a most important point, as in "curing" by dry heat that is the greatest difficulty the manufacturer has to contend with, and is the cause of more damaged goods than all other causes put together.

"Steam-cured" goods certainly do not show an efflorescence, but the process is damaging to the colours of the cloth.

Why there should be no efflorescence with the chloride process it is difficult to say, but I noticed in my experiments that rubber containing even 9 per cent. of sulphur showed no signs of it, although it could not be all combined, as it is for the most part easily removed with CS_2 .

3rd. The process being conducted at ordinary temperatures, no damage can occur to the cloth, which is very often the case with the dry and steam heat processes, as for these latter a temperature of 105°C . (220°F .) and of two hours' duration is thought to be very low, and even at this temperature wool is damaged to a certain extent, whilst at 121°C . (250°F .), a temperature which is often used, the damage is very considerable.

4th. The rubber "cured" with chloride, on account of the small percentage of sulphur it contains, combines greater strength with greater elasticity than if cured by the other processes, as I contend that rubber which is properly cured and contains the least proportion of foreign material, must give the best results. For instance, if a rubber be vulcanised with antimony sulphide, which, in order to produce good results, must contain a certain amount of uncombined sulphur, it will tend to be weaker and less elastic, because a greater percentage of foreign material is introduced which must destroy the properties to which rubber owes its special value. I had hoped to put this idea to a practical test, but failed to procure reliable samples. I may say that pure native Para rubber will keep quite sound for a period of 50 years, probably much longer, and it stands to reason that well-vulcanised rubber having the closest composition to this will last the longest.

5th. The chloride-cured rubber has a glossy appearance, and is transparent when held up to the light, which is much desired in a certain class of goods, and which cannot be obtained by any other process.

As regards the disadvantages urged against the chloride process there are some which would be very much minimised if only proper attention were paid to several details in the working of the process, and there are others which are imaginary or exist only where the process is not properly worked.

Before proceeding to discuss the objections, it may be as well to mention that the chloride process is not put forward as being applicable to rubber of above a certain thickness, about $\frac{1}{4}$ of an inch.

It would be impossible to vulcanise, for instance, mechanical goods which are so familiar to all.

The first objection I shall mention is the smell remaining in the goods after curing, especially with waterproof cloth, but my experience of the smell is that it entirely disappears if the goods are aired for

a few days provided attention has been paid to certain details which are often neglected. I shall briefly mention them. The quality of the solvent naphtha used for softening up the rubber should be carefully tested, especially as regards its being free from high boiling constituents, as these are apt to be left behind in the rubber, and when acted upon by chloride of sulphur produce resinous-like bodies, and which impart a very unpleasant and lasting odour to the goods. Another cause of a disagreeable odour which clings to the goods is produced by using an impure bisulphide of carbon.

The "stoving" of the goods after passing through the vulcanising solution should be very carefully done, as it not only removes any acid which may be formed on the surface, but also that disengaged in the inside of the rubber by the decomposition of the chloride. Of course it may be urged that the after treatment with ammonia neutralises all danger, but I deny this, as the acid from the inside of the rubber, if not removed by heat, will be very slow coming out to the surface, perhaps weeks, and will not be affected by the alkaline treatment.

Another objection against the process is as regards the lasting power of the goods. There can be no doubt that goods are produced by this process which do deteriorate quickly, but it can also be said for any of the other processes.

It is no fault of the process, as the careless manner in which it is sometimes worked makes one wonder how a presentable article is produced at all.

As it is only within the last year or two that the process has come to be more generally used and better understood, it is not to be expected that goods of any considerable age can be brought forward as a proof. I have seen waterproof cloth "cured" by this process eight years old, still in good condition, and have myself pieces of cut sheet which I cured three years ago, and they have not deteriorated in the least, either as regards elasticity or appearance. (Samples shown.) Again, I was lately told that, although the "cold cured" rubber might stand in this country, it would not in either very hot or cold climates, as in the former case it would become soft and in the latter hard. My experiments quite disprove the latter, and to test the former I took several pieces of the rubber which had been so cured, and heated them in an air-bath to 230°F . (110°C .) for three hours, and the only difference which I could observe was that they were a little less transparent; they certainly had not softened, become "tacky," or lost any of their strength and elasticity. If they had been so affected I should have concluded that they had not been well cured.

3rd. The process, owing to the use of CS_2 , is said to be hurtful to the health of the workmen. Of course this is owing to the air becoming laden with its vapour on its being expelled from the cloth, and, naturally, it must have a serious effect on the nervous system if no means be taken for its removal, as it is formed, from the workroom. In some works the health of the workman is of secondary importance to the bank book; but all the principal works have now adopted improvements whereby the fumes are, for the most part, confined and carried away before they pollute the air which has to be breathed by the workmen. An important factor in carrying out the chloride process is the choice of the diluent, the chief requisites of which are that it does not react with chloride, is a good solvent for rubber so that the same will quickly soften up and allow the chloride to penetrate its mass, besides being easily and entirely removed from the goods on warming and not be hurtful to the workpeople. CS_2 fulfils all

these with the exception of the last, and this is not urged as a serious objection by some manufacturers. The only other diluent which has found any favour is petroleum spirit, usually of a specific gravity about '700, and this principally because it has no effect on the workpeople. As far as I can make out this is its only recommendation. It is a bad solvent for rubber, and necessarily a very much longer time is required to allow of its softening the rubber so as to effect a thorough vulcanisation, and for rubber of any thickness ($\frac{1}{32}$ of an inch), I found it was not possible to effect a thorough vulcanisation in a reasonable time. Another disadvantage is that it reacts with the chloride, and the solution turns dark in colour if allowed to stand, and leaves behind a very disagreeable odour which it imparts to the goods, and the rubber is left in a "tacky" condition. In Table 1, Nos. 94—105 are the details of a few experiments done with petroleum spirit, and you will notice that the numbers for the sulphur are much below those for the corresponding strength when CS_2 was used as the diluent.

In conducting these experiments the rubber did not appear to soften up at all, as in the case with the CS_2 , and therefore it is probable that the sulphur was almost entirely on the surface, which could for the most part be removed by an after treatment with CS_2 . No doubt petroleum spirit can by repeated treatment with oil of vitriol and soda be very much much improved, *i.e.*, as regards its being acted upon by the chloride and also as regards its complete removal from the goods on "stoving" and smell, but it then costs considerably more than CS_2 , with which reagent I do not believe it will ever be able to compete for good work.

One important advantage which CS_2 possesses over petroleum is that the former has an almost constant boiling point, 46°C ., whereas the latter, although commencing to boil at a low temperature, rises considerably higher, and the residue is a dark, smeary looking substance.

The following is a boiling test of a sample of petroleum spirit, sp. gr. '701 at 15°C .

Began.....	53°C .
10 cc.....	67°C .
20 ".....	71.1°C .
30 ".....	75.7°C .
40 ".....	81.3°C .
50 ".....	85.8°C .
60 ".....	91.0°C .

80 ".....	105.1°C .
90 ".....	123.6°C .
95 ".....	156.4°C .

No doubt some one will be prompted to ask whether or not chloride of sulphur has any action on CS_2 . I was once asked this question before, and answered it in the negative, but I find that although no apparent action takes place, a change of some kind occurs in the properties of the vulcanising solution.

I made up a solution in the usual way, 1—30, and kept it for three days, and then vulcanised a few pieces of rubber. They should have been elastic and strong, but they tore quite easily. (Experiments 79—81.) The solution was now kept for six weeks and experiments repeated, when the same effect was noticed, although the solution had the same colour as when first made up. These experiments are Nos. 82—85, Table 1. The solution, although diluted to 1—60, showed the same peculiarity. (Experiments 86 and 87.) The per cent. of sulphur was approximately the same as when vulcanising on the usual way, so I think the action must have been a surface one, as a subsequent treatment with CS_2 removed the

bad effects. Experiments Nos. 23 and 24, Table III., were also done with this solution. In order to find out if the CS_2 had undergone a marked change I shook a portion of it with water, whereby all the chloride present was decomposed; the CS_2 was now separated, washed with water, and distilled, when it was found to all come over at approximately 46°C . A small residue of sulphur was left in the flask, which resulted from the decomposition of the chloride.

I can scarcely conclude this paper without mentioning another process, which was patented by Abbott, for vulcanising with the vapour of chloride of sulphur. In this process no diluent is required, the chloride alone, or mixed with other substances, being vaporised in a chamber in which the goods are hung up or passed through. After being exposed to the vapour for a certain time, they are exposed to the fumes of ammonia. No doubt a dark chloride could be used with advantage, as much less heat is required to vaporise it. I intended to carry out a series of experiments in order to determine in what proportion the sulphur was taken up, by exposing rubber for different times in the vapour of chloride, but the first few experiments convinced me that, for rubber of any thickness, it was not very applicable. No doubt, for very thin rubber, $\frac{1}{16}$ to $\frac{1}{32}$ of an inch in thickness, it is possible to obtain a good vulcanisation, but the rubber has quite different properties from the "cold-cured" article. Anyone with experience can tell at once whether, say, a pouch has been vapour-cured or not, as the virtue seems to be out of the rubber, and in many cases the outer surface is over "cured" in attempting to get the vulcanisation through and through.

My best thanks are due to Messrs. Matthews and Burbridge for the valuable help they have given me, and also to Messrs. Shaw and Anderson for the care bestowed upon the analyses.

DISCUSSION.

The CHAIRMAN felt quite sure that he was only speaking the mind of the meeting when he said that they were all indebted to Mr. Fawsitt, not only for bringing before the Section the important subject of the vulcanisation of rubber, but for the manner in which he had done it. The literature of the subject, as far as it went, was good, but exceedingly scant, and although a few excellent papers had been read to the Society and had appeared in the Journal, notably those by Burghardt and by Thomson, the subject had neither been investigated nor ventilated to anything like the extent which its growing importance deserved. He considered these papers on technical subjects of great importance, and regarded this as a typical one. His own experience was confined chiefly to the deterioration of "proofed" goods, and its causes, questions regarding which were constantly pending between the manufacturers of the cloths and linings and the proofers. It was extremely difficult, when these differences arose, to avoid litigation of the most expensive kind, there being little information on the subject except that excess of oil in the fabric might easily cause damage, a fact which was universally admitted, although there were numerous other possible causes. The crude condition of this question might be judged of from the circumstance that a minimum proportion of oil in the cloth was commonly stipulated for—it might be 2 per cent. or 1 per cent.—regardless of any other circumstances or conditions, which might have as much to do with deterioration of proofing as the amount of animal or vegetable oil in the fibre. He would just refer to a few of these. There were, first,

the quality of the raw rubber, which was variable, from "Para" downwards; secondly, the proportion of added foreign ingredients, chiefly mineral matters such as carbonate of lime, clay, &c., which "sponged" the rubber and made it more readily oxidised by the oxygen of the air; thirdly, the quality of the naphtha employed, which, if not free from high boiling point oils, would leave the latter in the rubber where it would act like an oil; fourthly, the introduction of rubber substitutes; fifthly, the nature of the oil in the fabric; sixthly, excess of sulphur; and, lastly, the *ratio* of the oil on the surface and in the substance of the cloth to the rubber employed, as it was quite clear that proofers could not go on reducing the quantity and quality of the rubber employed without at the same time getting the proportion of oil reduced to match, otherwise they might expect damage. Very often it was recklessly alleged that because the fabric contained more than a fixed and definite amount of oil, the damage was due to that cause without reference to any other condition, which he considered unfair to the manufacturer. He believed that if the cost of a single action at law, or very much less, were expended on an honest and well-conducted investigation, which should be as exhaustive as possible on these points, by a representative manufacturer and a chemist, with appeal to an oversman, much misunderstanding and threatened litigation might be avoided; both manufacturers and "proofers" would know what to stipulate for in making contracts. When questions relating to deterioration of proofed garments or other goods arose, an examination of them would show where the blame lay, and the whole trade would be benefited. He begged to move a hearty vote of thanks to Mr. Fawsitt for his excellent paper, which was unanimously accorded.

Mr. IRVINE remarked that it was impossible for him to criticise Mr. Fawsitt's paper, for the author had gone fully into all the questions and difficulties which seemed to surround the process of vulcanising with chloride of sulphur. He remarked that all the processes employed in the manufacture of india rubber goods were faulty in so far as they were dependent upon the use of solvent materials which in themselves were extremely dangerous and often hurtful to the health of the workmen employed. Of course the ideal method of using this valuable material would be in the condition in which it is taken from the tree (that is, as milk), but hitherto the rubber as received in this country had defied all his efforts to bring it back to its native state. He, however, suggested this as a field holding out brilliant prospects to the hosts of young chemists whose chief difficulty lay in not knowing what fields into which they might push their energies. Such a process if found would be of incalculable value.

Mr. FAWSITT, in reply, said that the Chairman's remarks on the deterioration of "proofed" goods showed that he had given the subject close attention. His own experience lay principally with goods which had been "enred" with chloride, and the damage to the cloth in this process often arose from the acid not having been entirely removed before the cloth was rolled up. In order to free the cloth entirely from acid more "stoving" was required than it usually got, and the after treatment with ammonia would, if much acid be left, leave a considerable amount of chloride of ammonium in the cloth, and impart to it a whitish appearance, and in time cause more or less damage. He had found that cloth moistened with a neutral 2 per cent. solution of chloride of ammonium, on drying and exposing

to the air, turned slightly acid. As regarded the deterioration of rubber coating, this was, he thought, in the majority of cases owing to the "proofing" mixture not being properly prepared. It was well known that certain classes of "recovered" rubber were very dangerous to use, especially in the dry heat process. Again, the "substitute" made by acting upon oil with chloride, unless very carefully prepared and freed from acid, would invariably cause premature decay as the acid vapours were slowly emitted, and would rot the "proofing" as well as the cloth. If the surface of the rubber coating were freed from excess of sulphur or chloride of sulphur, as the case might be, by a solvent or other reagent, a beneficial effect, as regards the deterioration of the rubber, was produced, and if CS_2 were used the oil was at the same time partly removed from the cloth. As regarded the action of oil upon the rubber, it had, as the Chairman remarked, a damaging effect, especially an oil which oxidised readily, but he thought that oil was often blamed when the cause should be looked for elsewhere. The Chairman had thrown out a very good suggestion in stating that if the expenses incurred in litigations were expended in investigating the cause of dispute, it would lead to more just results. As regarded Mr. Irvine's remarks, the use of solvents in the manufacture of rubber was not attended with any great danger if the workpeople were instructed as to their properties; certainly to a far less degree than their manufacture. There was one point which should be carefully attended to when using CS_2 , and that was that its vapour took fire at about 15°C . (302°F .), so that a plumber with his bolt, for instance, which would not melt solder, might cause an explosion.

NOTE ON THE CONDENSATION OF CARBON PARTICLES IN SMOKE.

BY R. IRVINE, F.R.S.E., F.C.S.

IN the manufacture of lamp black hydrocarbons are burned in an atmosphere with a limited supply of oxygen; the resulting dense black smoke is conducted into large chambers, where on account of the extremely sluggish draught it is allowed to roll about until the particles, by attraction between themselves, gradually coalesce into masses, which after a lengthy period fall on the floor in the form of soot. This process is exceedingly slow, and the product obtained from even an enormous condensing space, is comparatively very small. Consequently this manufacture is one carried on on a limited scale, considering the magnitude of the plant required.

Following the lead given by Professor Lodge of Liverpool, in his experiments upon lead stythe, I, assisted by my friend Mr. J. Lillie Mitchell, undertook a series of experiments with a view to more rapid condensation of smoke carbon; and for this purpose erected a glass structure 5 ft. \times 4 ft. \times 4 ft., in which were fixed two malleable iron plates, provided with a great number of points—these facing each other; the plates being separated by a distance of from two to three feet, and all the conducting surfaces except these points being carefully insulated with shellac varnish.

This chamber was filled with smoke produced by burning pitch oil, which retained its opacity for at least two hours; so much so that on then looking through the chamber, a bright light placed on the

other side was totally obscured by the vapour. The chamber was now refilled with smoke, and the whole atmosphere therein was to a greater or less degree electrified by coupling the conductors which were connected to the plates with a small dynamo. The effect immediately produced was exceedingly striking, the minute particles of carbon at once separated from the opaque smoke, and were attracted to or driven from the points of the plates, congregating together in a most extraordinary manner; and in the space of two or three minutes the atmosphere in the glass chamber was almost entirely cleared of smoke. The prohibitory cost of electricity has, however, prevented the application of this process on the large scale, for the present at least.

[This paper was illustrated by practical demonstration of this experiment.]

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

Reasons why Iron Water-Mains corrode if not Turred.
G. Weissmann. Chem. Zeit. 13, 433.

EVEN if iron water-mains contain only traces of sulphur and phosphorus, they are readily corroded if not turred. This is especially the case if the soil in which they lie be rich in organic substances such as humic acid, contain nitrates and ammonia compounds, or if it be saturated with water containing carbonic acid. Access of air is equally detrimental. It is a well-known fact that brine has no corroding action on iron tubes which are turred, so long as the latter are kept full. This applies equally to pure water.

—A. R.

The "Arktos" Cold Air and Freezing Apparatus. L. Perkins. Engineer, 1889, 209.

AMONGST other difficulties which have been connected with Carre's apparatus, and prevented its use on a large scale, was the evaporation of some of the water with the ammonia from the heating vessel, the evaporation taking place at about 270° F. This, passing over into the cooler, lessened the effect in the manner that will be seen. This has been overcome by L. Perkins in the "Arktos." The Figure shows in cross section two tubes, A, B, connected by small tubes C; these tubes form the vessel in which the evaporation is performed by the application of heat, and in which the ammonia and water again combine when the supply of

heat is stopped. It is therefore called the combiner. The saturated solution of ammonia, containing about one-third by weight of ammonia, is placed in this vessel and heat applied to the liquid by a Bunsen flame at D below the lower tube of the combiner, or, as in most cases, and always for large apparatus, by means of hot water or steam tubes passed through it. By the application of this heat to the liquid the ammonia rapidly evaporates, and when first starting the apparatus a little ammonia and water vapour is allowed to escape through a water-sealed pipe, which is afterwards capped. The escape of ammonia is very small, only sufficient to ensure the discharge of all or nearly all the air from the apparatus. If at this stage the heat supply were stopped, there would be a vacuum of about 25 in. as a result of the escape of gas and vapour and the cooling of the gaseous and liquid contents. The ammonia vapour passes through the tube E, which is surrounded by a water jacket, where it is condensed, the liquid ammonia passing into the freezing vessel F, which, when the apparatus is first put to work, contains water up to the level of the top of the small vessel G. The ammonia, being lighter than the water, remains afloat, and as it increases in quantity with evaporation from A B, it drives the water from F, through the small holes in the bottom of G, and thence down the syphon tube H into the vessel A. Here any ammonia that may have been carried over is again heated, and passes over through the condensing tube to E. This evaporation then continues until all the ammonia is in the vessel F, and all the water driven therefrom through the syphon H, with the exception of the small quantity, which being below the little holes K in the bottom of G, cannot be driven over. Now the supply of heat is stopped. The whole apparatus cools down, partly by the continued cooling action of the jacketed tube E, and partly by cold water, which is allowed to trickle over B. The vacuum of about 25 in. is immediately brought about, and the

re-evaporation from the freezing vessel F proceeds, giving temperatures that will freeze large quantities of mercury, until all the ammonia is again over in A B recombined with the water. The re-evaporation from F takes much longer than the evaporation from A B, and in some applications of the freezing or cooling apparatus need only

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	1/4d.
Above 8d., and not exceeding 1s. 6d.	1d.
„ 1s. 6d. „ „ 2s. 4d.	1 1/2d.
„ 2s. 4d. „ „ 3s. 4d.	2d.

be done once per day. From this it will be seen that, for the proper working of the apparatus, the capacity of the vessel A B must be to that of F very near the proportion which the water bears to the liquid ammonia.

In the whole apparatus there is not a single moving part, not a single valve, the whole apparatus is a closed-up system, and in the large apparatus the control of the supply of heat is by cocks on pipes apart from the "Arkos."

—O. H.

PATENTS.

A Vertical Grinding Mill for Grinding all kinds of Minerals. G. and R. A. Norman, Sheffield. Eng. Pat. 2103, February 17, 1888. 6d.

Two or more chilled iron or steel discs are keyed one above the other upon a vertical spindle, which is made to revolve by gearing fitted either at the top or bottom. A casing of iron or steel rings encloses the spindle and discs. The mineral to be ground is fed in upon the top disc, and is ground between the periphery of the revolving disc and the inner surface of the casing, and falls through upon the next lower disc, and so on to the bottom where the ground mineral is removed by a revolving scraper.—H. S. P.

Improvements in Machinery or Apparatus for Grinding, Pulverising, and Separating Animal, Vegetable, and Mineral Substances. W. H. Thompson, Old Charlton, H. E. Hunt, London, and C. W. Kutto, Stoke Newington. Eng. Pat. 3296, March 3, 1888. 1s. 1d.

This has reference to improvements in machinery previously described in Eng. Pats. 4325 of 1876 and 12,560 of 1881, and refers principally to the parts employed for separating the pulverised substances, and to combining those parts with the mill, so as to effect more rapid and efficient working, and to rendering the various parts of the mill and sifting apparatus more accessible. For this purpose the casing of the mill is so arranged as to admit of the propelling blades being applied to the driving discs, for the purpose of retaining the substance to be pulverised under the action of the ball until it is reduced sufficiently fine for sifting, and then for propelling it to the sifting apparatus. This latter is mounted on wheels, and runs on a tramway, thus rendering it and the mill easily accessible for adjustment and other purposes. A further improvement consists in feeding the mill with the material, by means of a vibrating and adjustable shoot. In wet grinding, the mill is formed with a casing, on one or both sides, constructed to form a tank, where the substances are kept in suspension, by the agitation of the mill, until sufficiently pulverised, when the floating particles are caused to flow over or out through spouts or apertures into several settling tanks, so arranged as to discharge one into the other, the coarser particles being deposited in the first tank, while the lighter ones will be carried into the next tank or tanks. The details of the improvements are protected by six claims, and are illustrated by three sheets of drawings.

—E. S.

Improvements in or connected with Apparatus or Machines for Heating, Cooling, or Condensing Fluids. A. Rathbone, Warrington. Eng. Pat. 1689, March 27, 1888. 8d.

THE improvements described apply to apparatus for heating, cooling, and condensing which are of the tubular type; the heating or cooling or condensing body passing over the external or internal surface of a tube, whilst the body operated upon passes over the other surface. In order to increase the length of path of the material over the surface of the tube with which it is in contact, the patentee provides the interior of a tube with a sheet, bar, or second tube of any shape or structure, plain, corrugated, or otherwise shaped, so as to ensure a spiral or helical path, and so secure the longest possible path of contact with the surface of the tube separating the materials which convey or subtract the heat from each other. Fourteen variations are shown in the specification.—C. C. H.

An Improved Automatic Separator and Purifier of Solids and Fluids. P. A. Maignen, London. Eng. Pat. 4760, March 28, 1888. 8d.

THIS specification describes and illustrates 19 modifications of a form of apparatus proposed by the patentee for the separation of suspended solid matter from water or other liquid. In the interior of a vessel, preferably of a cylindrical form, a number of obtuse conical and perforated vessels are superposed base-upwards; the apex of each is directed towards the centre of the cone below, and open so as to direct the stream of water issuing against the said perforated base below. Passage of a current of water through such an apparatus results in the formation of eddies, and "a large flow of the water is retained in a dormant condition, which allows the suspended matter to deposit with the least possible hindrance.—C. C. H."

Improvements in the Method of and Apparatus for Superheating Steam. R. Shackleton, Bradford. Eng. Pat. 5812, April 19, 1888. 6d.

ATMOSPHERIC air heated to a high temperature by any convenient means is passed or forced through a series of pipes placed in the steam space of a boiler; or the steam pipe leading from the boiler is heated by means of an annular jacket of hot air. By either means, dry steam of a higher temperature than that corresponding to its pressure is obtained.—C. C. H.

An Improvement in Machines for Agitating or Mixing Substances, Solid and Liquid. W. Smith, Barnard Castle. Eng. Pat. 6124, April 25, 1888. 6d.

A RECEPTACLE containing the substances to be mixed has a ridge on the bottom, internally, and is mounted on two gudgeons. On a reciprocating motion being given to it, the enclosed substances are thrown from one side to the other, over the ridge, which stays the progress of the substances until the vessel has been lifted high enough to throw them over the ridge. The invention is specially applicable for washing and churning. The claim consists in the ridge at the bottom of the receptacle for the purpose described.—E. S.

Improvements in Means for Filtering Water or other Liquids. O. A. Berend, Hamburg, Germany. Eng. Pat. 6282, April 27, 1888. 8d.

IN the interior of a cylindrical vessel A, concentric spaces are formed by means of any number of cylinders B B, D D,

the latter with their open ends upwards, the former with their closed end upwards and the open end downwards. These concentric spaces, therefore, communicate with each other alternately at their upper and lower parts, and communication is likewise facilitated by perforations at *b b'*.

Filtering media of any appropriate kind is packed in the spaces so formed, through the doors c^2 , and as a result any water passing through the apparatus necessarily pursues a tortuous path through the media before arriving at the porous carbon block F and leaving the filter by the pipe E.

—C. C. H.

Improvements in the Method of and Apparatus for Forcing and Drawing Chemical or other Liquids. S. Spencer and J. S. Lord, Bes-er-o'-th-Barn. Eng. Pat. 7768, May 28, 1888. *8d.*

THE improvements in this patent have for their object the prevention of the chemical liquid acting injuriously on the interior of the pump. This is effected by employing a volume of air between the piston of the pump and the liquid to be raised, so that the liquid is prevented from coming in contact with the pump cylinder and piston. The receiver is made, preferably, of earthenware, and is formed with an inlet and outlet ball valve. The pump can be placed at the side of the receiver, or over it, as shown in the drawing accompanying the specification. On moving the piston outwards a vacuum is made in the receiver, the inlet valve is raised and the liquid enters. At the upper end of the pump cylinder is an air-opening; on the piston passing this, air enters and fills the cylinder. The return stroke of the piston closes the inlet valve, and the compressed air forces the liquid through the outlet valve, the compressed air being allowed to escape through a port on the piston reaching its lowest position. By employing two receivers the pump can be made double-acting.—E. S.

Improvements in Apparatus for Evaporating Brine and for similar Purposes. H. H. Lake, London. From J. M. Duncan, Silver Springs, Wyoming, U.S.A. Eng. Pat. 785, January 16, 1889. *8d.*

THE apparatus devised is a special form of vacuum pan in which the object aimed at is to so construct the heating

Fig. 1.

tubes or coils that they may be readily and expeditiously removed from the interior of the apparatus. A is the heating portion of the pan connected by the swan neck B in the usual way with the condenser C, and provided with sight opening P, and the various appliances common to most forms of vacuum pans. K K are hinged doors through which access is had to the heating tubes. S is a closed vessel which receives the salt as it is crystallised and precipitated, so that it can be removed in a manner readily seen without stopping the operation in the pan; O is the brine supply pipe. D in Fig. 2 shows the heating pipes

Fig. 2.

arranged between two diaphragms $m m$, which with the sides of the pan form the circulating spaces M M'. Fig. 3

Fig. 3.

shows the manner in which the pipes are supplied with steam and condensed water removed. F is a common steam supply passage into which the inlet manifold d , receiving the ends of the pipes D, enters by the nipple g ; the joint of each manifold is made steam-tight by the

pressure of the set screw *h*. The outlet may be managed in the same way, or each manifold at the outlet end may communicate by a separate drip pipe *i* with a main drain pipe *l*. The facility with which a section of pipes may be removed is apparent. The interior of the pan is lined with glass or porcelain to obviate incrustation.—C. V. H.

II.—FUEL, GAS, AND LIGHT.

On the Testing of Spent Substances from Gas Purification. E. Moldenhauer and W. Leybold. Journ. f. Gasbeleucht. 32, 155.

See under XXIII., page 421.

PATENTS.

Improvements in the Manufacture of Illuminating Gas and in Apparatus employed therein. J. H. R. Dinsmore. Liverpool. Eng. Pat. 2096, February 11, 1888. 1s. 3d.

THESE improvements refer to a process for converting into permanent illuminating gas the tar obtained during the distillation of coal in closed retorts. The main features of the process have already been mentioned in this Journal (1888, 741; and 1889, 272). The present specification contains 27 claims, and is illustrated by eight sheets of drawings.—A. R. D.

Improvements in the Manufacture of Vapour and in Mixing Nozzles therefor. J. J. R. Humes, London. Eng. Pat. 2111, February 11, 1888. 8d.

THIS is a device for impregnating a gas with liquid hydrocarbon. Both gas and liquid are admitted to the apparatus under pressure. The latter is pumped with a portion of the former into a preliminary mixing chamber, and the combined stream is joined at right angles by the remainder of the gas admitted from an annular passage close to the delivery point.—A. R. D.

Improvements in the Manufacture of Gas and in Apparatus used therefor, the said Apparatus being adapted in other Manufactures. W. Foulis and A. J. Liversedge, Glasgow. Eng. Pat. 4372, March 22, 1888. 8d.

THE inventors propose to free a gas from the solid or liquid impurities mechanically suspended therein by imparting to it a rapid rotary motion. The impurities being heavier than the gas are projected by the centrifugal action thus induced against the periphery of the vessel in which the operation is conducted. The apparatus consists essentially of an outer casing or enclosing vessel through which runs a shaft carrying such an arrangement of fans as may be found most suitable for imparting the motion desired.—A. R. D.

Improvements in or relating to Hydrocarbon Furnaces. W. P. Thompson, Liverpool. From the Porcelain Dental Art. Co., Detroit, U.S.A. Eng. Pat. 4402, March 22, 1888. 8d.

THIS specification describes an apparatus for heating a muffle furnace with a mixed blast of air and hydrocarbon. As the improvements refer mainly to the arrangement of the details of the apparatus, the specification with its drawings should be consulted.—A. R. D.

Apparatus for Supplying Furnace Fires with Moistened Air. W. Le Las and A. Robin, Paris, France. Eng. Pat. 5527, April 13, 1888. 8d.

THIS apparatus is intended for furnaces working under a forced draught. The air blast is made to pass through a moistening chamber where it comes into contact with a wetted screen or a shower of water, and whence it is admitted to a

box connected with the ash pit. Each firebar consists of a number of plates very deep in the middle and kept apart by distance washers. With this construction the moistened air has to pass over a very extended surface, and the bars are effectually prevented from overheating. The furnace is constructed with an inner and an outer fire-door, between which a regulated supply of moistened air is admitted to the fire to cool the metal and promote the combustion of smoke.—A. R. D.

Improvements in Gas-Producers. E. Brook, Huddersfield. Eng. Pat. 6454, May 1, 1888. 8d.

THESE improvements have reference to details in the construction of gas-producers of the ordinary kind. Round the lower part of the producer is placed a water jacket through which run tuyeres for supplying air to the interior of the mass of fuel. Air is admitted to the exterior portion of the fuel from an annular blast chamber below the water jacket. The producer is provided with a water base, and the ashpit is thus kept luted. Just below the level of the working doors is placed a central cross-bar which serves to support temporary bars when lighting up, clinkering, &c. This crossbar may be made hollow and perforated at the top so as to serve instead of tuyeres for the admission of air to the interior of the producer.—A. R. D.

Improvements in Gas Producers. A. Wilson, Stafford. Eng. Pat. 6514, May 2, 1888. 8d.

THESE improvements have reference to producers that may advantageously be used for the manufacture of gas for driving engines. After leaving the producer, the gas is caused to pass through a regenerator in order to heat the air and steam used in the process. This enables a larger percentage of steam to be decomposed, and tends greatly to the enrichment of the gas. When a gas-holder is used the inventor employs also a water seal or luted escape to provide for the automatic cessation of production when the holder is full. When the pressure in the holder reaches a certain point, the water seal allows the air and steam blast to escape without entering the producer. The charging-hopper, chimney and a working-hole are fitted in a revolving plate that covers an opening in the top of the producer. By this means any one of the three can be brought over the opening at will.—A. R. D.

Improvements in the Purification of Carburetted Hydrogen or Coal Gas. W. A. M. Valon, Ramsgate and Brin's Oxygen Co., Westminster. Eng. Pat. 6920, May 9, 1888. 6d.

COAL gas, from which the tarry and ammoniacal impurities have been eliminated, is mixed with oxygen and passed through purifiers containing caustic alkali—preferably lime. The sulphur compounds and the carbonic acid combine with the lime, with separation of a considerable proportion of free sulphur. To a thousand volumes of the gas one volume of oxygen should be added for every 100 grains of sulphuretted hydrogen present per 100 cub. ft. of gas.—A. R. D.

Improvements in Artificial Fuel. H. Williams, London. Eng. Pat. 7219, May 15, 1888. 4d.

SMALL coal or breeze, tar, and spent lime taken direct from the gas purifiers are mixed in a pug-mill, and the resulting mass made into blocks and dried. Even if the tar be omitted an excellent artificial fuel is obtained.—A. R. D.

Improvements in the Method of and in Means and Appliances for Measuring Air, Gas, and other Fluids. H. Lane, London. Eng. Pat. 7674, May 25, 1888. 8d.

A HOLLOW vessel, made in two parts, with flanges for bolting together, is fitted with a flexible air-proof diaphragm

in combination with a valve, so formed and fitted as to become automatically reversed by the increase of pressure caused by the check imparted to the fluid when the receiver is filled (arising from the difference of pressure between the induction and eduction fluid), and thus also rendering the flow continuous. "A valve box and valve (preferably of the piston type) are fitted, having passages to each half of the vessel, and induction and eduction ports, and connexions from and to other vessels, from which the fluid is drawn." The valve has a rod passing through a stuffing-box, and is connected in any convenient manner with any suitable recording instrument. The action of the valves and other parts is fully shown in the drawings accompanying the specification. The improvements are protected by three distinct claims.—E. S.

Improvements in the Treatment of Peat. S. Pitt, Sutton. From D. Aikman, Montreal, Canada. Eng. Pat. 13,679, September 21, 1888. 8d.

AFTER being freed from sticks the peat is mixed to a pulpy state in a trough with the aid of open steam. It is then dried between heated rollers, whereby the material is obtained in the form of films or flakes, and the more volatile constituents of the peat are driven off. These are recovered and again mixed with the solid portion, and the whole subjected to a pressure of 10 or 12 tons per square inch in moulds heated to a temperature of from 800° to 1,000° F. The analysis of the hard glazed block thus obtained is approximately as follows:—

	Per Cent.
Moisture	3.84
Volatile combustibles	41.22
Fixed carbon	18.04
Ash	6.90

—A. R. D.

Improvements in Apparatus for Testing and Detecting the Presence of Gases or Gaseous Mixtures. T. Shaw, Philadelphia, U.S.A. Eng. Pat. 18,105, December 11, 1888. 11d.

See under XXIII., page 425.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

The Collection of Ammonia and Tar from Coke Ovens, with special regard to the Conditions in the Ostrau District. W. Jicinsky. Osterr. Zeits. f. Berg.-u.-Hüttenw. 36, 527 and 540.

ANALYSES of a few coals are given, together with the yields of gas and coke on dry distillation. The amount of ammonia produced is not proportional to the quantity of nitrogen in the coal. About three-fourths remain in the coke, the remainder goes to form ammonia, cyanogen, and some also escapes as free nitrogen, so that only between 0.089 and 0.188 per cent. of the total nitrogen of the coal is converted into ammonia. A table of results are given which demonstrate this.

The tar usually amounts to between 2 and 3 per cent. of the coal, and is generally about one-third to a quarter of that obtained in laboratory experiments. Coke-oven tar contains from 0.9 to 1.06 per cent. of benzene, 4.26 to 5.27 per cent. of naphthalene, 0.57 to 0.64 per cent. of anthracene, 50 per cent. of pitch, and 40 per cent. of other residual matter.

The following are analyses of coke-oven and illuminating gases:—

	Coke-oven Gas.	Illuminating Gas.
	Per Cent.	Per Cent.
Benzene	0.61	1.54
Ethylene	1.63	1.19
Sulphuretted hydrogen	0.43	..
Carbon dioxide	1.41	0.87
Carbon monoxide	6.49	5.40
Hydrogen	53.32	55.00
Methane	36.11	36.00
	100.00	100.00

—A. W.

Fichtelite. C. Hell. Ber. 22, 498—502.

FICHELITE occurs together with retene in the turf beds of Redwitz in the Fichtel mountains, and is found in the fossil stems of the sporadic bog-fir *Pinus uliginosa* N.

It has been previously investigated by Trommsdorff (Ann. 21, 126), Bromeis (Ann. 37, 304), and Clark (Ann. 103, 236), and, according to the last named, who obtained a number of chloro- and bromo-derivatives in an impure condition, its constitution is $C_{15}H_{26}$.

It is best separated from retene and obtained in a pure condition by repeatedly recrystallising from a mixture of alcohol and ether, from which it separates in long prismatic crystals melting at 46°. The mother-liquors yield, on further evaporation, first retene and, finally, a brown soft mass with a strong smell of vanilla.

Vapour density determinations by V. Meyer's method at 440° seem to show that it has the formula $C_{15}H_{26}$ or $C_{15}H_{26}$; it would therefore be a tetra- or di-hydride of a sesquiterpene. On the other hand, it is possible that partial dissociation may have taken place, and the true formula is $C_{30}H_{54}$; this formula agrees better than any other with the author's and Clark's (*loc. cit.*) analyses, and the high boiling point of this hydrocarbon also points to a much more complicated constitution than that indicated by the vapour density determinations.

Fichtelite is only acted on extremely slowly when boiled with fuming sulphuric acid, potassium bichromate and sulphuric acid, or a 10 per cent. solution of potassium permanganate, but when treated with chromic acid in glacial acetic acid solution it seems to be oxidised to carbonic acid. It is not acted on by cold fuming nitric acid, but when boiled with nitric acid of sp. gr. 1.32 it yields oxalic acid. Bromine acts on it very readily, but the products could not be obtained free from unchanged hydrocarbon.—F. S. K.

The Hydrocarbon $C_{60}H_{122}$. C. Hell and C. Hägele. Ber. 22, 502—505.

THE highest saturated hydrocarbon, the molecular weight of which is known, is $C_{35}H_{72}$, and it is probable that the solid paraffins obtained from shale, wood, &c. do not contain more than 30 carbon atoms.

A hydrocarbon $C_{60}H_{122}$ can be prepared artificially from myricyl iodide, which latter is easily obtained by treating the alcohol with iodine and phosphorus according to Pieverling or Walter's method. The iodide is carefully heated at 120°—140° with about one-tenth of its weight of finely-divided potassium or sodium; the product is then extracted with boiling water, alcohol, petroleum spirit, and glacial acetic acid consecutively, to remove the unchanged iodide, and recrystallised from benzene. It separates in the form of a white powder, melts at 101°—102°, and is very sparingly soluble in alcohol and ether, more readily in petroleum spirit and glacial acetic acid, and most easily in chloroform and benzene. It is partially decomposed when

aniline which assumes a dark colour by the action of light. It therefore seems necessary that the hydrocarbon should be treated more thoroughly than is customary with sulphuric acid, to obtain an absolutely pure product.

Aniline, ortho- and paratoluidine, free from thiophen, yield only traces of magenta with arsenic acid, whereas by adding nitrothiophen to the nitro-derivatives previous to reduction, the formation of the colouring matter takes place as usual.

—A. R.

On the Action of Acetone on Ortho- and Paramidophenol.
C. Eng'ler and A. Kauer. Ber. 22, 290—215.

Acetone acting on amidophenols ought to produce, according to analogy, hydroxy- α - γ -dimethylquinoline—

Dry *o*-amidophenol hydrochloride was heated with 3 molecules of acetone for 48 hours to 170°—180° C. On opening the tubes a gas escaped consisting of 90 per cent. of methane. The brown contents of the tubes were boiled with dilute hydrochloric acid, the remaining residue was dissolved by acetone, and the whole mass then heated by steam, when acetone and its condensation products distilled over, whilst some resinous matters were precipitated. By partial neutralisation with caustic soda and evaporation more resinous matters separated. After filtration the basic compounds were precipitated by carbonate of soda solution, care being taken not to use excess, and the yellow floccular precipitate was washed with hot water until it was of the consistency of a thin paste. From the filtrate the amidophenol can be recovered. The dry residue was dissolved in absolute alcohol and to the solution concentrated sulphuric acid was added. After cooling needle-shaped crystals separated. These were filtered and washed with alcohol and ether until colourless. The crystals were then dissolved in water and after addition of potassium bichromate an abundant yellow precipitate was obtained, which was filtered and washed with cold water. After standing with carbonate of soda solution the base is obtained in flakes, which become crystalline after some days. The new compound is soluble in dilute, with difficulty soluble in concentrated caustic soda, and these solutions produce orange- and Bordeaux-red coloured precipitates when treated with diazo-chlorides. The colour produced with β -naphthylamine dyes silk in an acid alcoholic solution a yellowish-brown with a red shade. Ferric chloride produces a green coloration, disappearing gradually on heating, but at once on acidifying. The base is easily soluble in ether, benzene, acetone, alcohol, and chloroform, less easily in petroleum spirit, nearly insoluble in water. It is scarcely volatile with steam, but may be sublimed, and possesses the peculiar odour of quinoline derivatives and an intensely bitter taste. It melts at 65° C., boils at 281° C. On addition of bromine to the hot alcoholic solution a yellow crystalline precipitate separates. The compound is *o*-hydroxy- α - γ -dimethyl-quinoline, $\text{C}_{11}\text{H}_{11}\text{NO}$.

The sulphate, hydrochloride, bichromate, picrate, and platinum double salt are described. The yield was at the best 20 per cent. of the amidophenol.

Para-hydroxy- α - γ -dimethylquinoline was obtained by heating *p*-amidophenol with three times its weight of acetone for from 2—3 days to 170°—180° C., when a gas was formed containing 87 per cent. of methane. The purification was effected in a similar manner to that already described. The yield was 12 per cent. of the theoretical one. The base crystallises from alcohol in prisms or plates melting at 214° C., boiling above 360° C. with decomposition. It is nearly insoluble in cold and hot water and benzene, with difficulty soluble in ether, easily soluble in ether and acetone, in acids and caustic alkalis (with the exception of ammonia). Carbonic acid precipitates the alkaline solutions. The alkaline solutions yield with diazo-chlorides coloured precipitates; the acid alcoholic solution of the colour from β -naphthylamine dyes silk a beautiful red colour. Ferric chloride produces in its alcoholic solution

a brown coloration, disappearing on addition of acids. The hydrochloride, sulphate, bichromate, and platinum double salts are described.—A. L.

On Aldehyde Blue. L. Gattermann and G. Wichmann.
Ber. 22, 227—236.

Action of Aldehyde on Pararosaniline at Ordinary Temperatures.—5 grms. of pararosaniline were dissolved in a mixture of 55 grms. of concentrated hydrochloric acid and 55 of water, and to the solution 22 grms. of aldehyde were added. After 24 hours the reaction terminates. The blue solution was diluted to one litre, and the colouring matter precipitated by common salt. The colour thus obtained was redissolved in absolute alcohol and recovered, after evaporation of the alcohol, as a mass with a bronze-like lustre.

Action of Paraldehyde on Pararosaniline at Ordinary Temperatures.—The reaction and the result were the same as above described. The blue colouring matter has all the properties of the rosaniline derivatives. On reduction it yields a leuco-base, which, however, could not be obtained crystalline. It is re-oxidised in the air, as well as by oxidising agents, to the original blue colour.

To discover the constitution of the colour a quantity of the product was heated for five hours with concentrated hydrochloric acid to 220° C. A colourless base was thus obtained which could not be crystallised. When, however, the aldehyde blue was distilled, first hydrochloric acid and water escaped, then an intense odour of quinoline was observed, and a heavy oil condensed, eventually solidifying. The analysis gave figures for $\text{C}_{10}\text{H}_9\text{N}$, the formula of a methylquinoline. It was proved to be identical with the homologue of Claus' diquinoline, prepared by heating quinaldine hydrochloride for eight hours to 220° C. The molecule of this body was found, according to Raoult's method, to consist of three quinaldines, $(\text{C}_{10}\text{H}_9\text{N})_3$.

Aldehyde blue seems, therefore, to be a quinoline derivative and probably $\text{C}(\text{C}_{10}\text{H}_9\text{N})_3(\text{Cl})\text{HCl} + 3\text{H}_2\text{O}$.

Action of Paraldehyde on Rosaniline at Ordinary Temperatures.—The experiments were conducted in the same way as above, and a blue obtained of the formula $\text{C}(\text{C}_{10}\text{H}_7\text{NCH}_3)(\text{C}_{10}\text{H}_9\text{N})_2(\text{Cl})\text{HCl} + 3\text{H}_2\text{O}$.

The constitution of the Aldehyde blue being satisfactorily explained, the authors tried to prepare the green from this compound, but all experiments failed. It was at last observed that when salting out the blue colouring matter the mother-liquor always remained deeply coloured. This mother-liquor yielded without any difficulty Aldehyde green. When acting, therefore, with aldehyde on pararosaniline two blue bodies are formed, one of which is capable of yielding under certain treatment Aldehyde green.

The Aldehyde blue is not applicable to dyeing purposes on account of its high price, and because it is not fast to light. But it is useful for microscopical purposes.

If the action of aldehyde and paraldehyde on pararosaniline be carried out at a higher temperature, say at 50° C., a different result is obtained, a blue colouring matter being formed of another composition.—A. L.

On the Constitution of the Beta-Naphthol-Alpha-Monosulphonic Acid and the Beta-Naphthol-Alpha-Disulphonic Acid (Salt R.). W. Pfützinger and C. Duisberg.
Ber. 22, 396—399.

BERGER's beta naphthol-alpha-monosulphonic acid was converted in the autoclave into a beta-naphthylamine sulphonic acid identical with the one obtained by the Badische Anilin und Soda Fabrik by heating beta-naphthylamine with fuming sulphuric acid. From this body was prepared the hydrazine compound by treating the diazo-compound with stannous chloride and hydrochloric acid. After purification the hydrazine group was eliminated from this body by boiling with copper sulphate, and the resulting naphthalene sulphonic acid was fused with caustic soda. Alpha-naphthol, of the melting point 96° C., was obtained. If Witt's experiments (this Journal, 1889, 277) and the above are considered together, they prove that the beta-

naphthol- α monosulphonic acid must be either represented by the formula—

Beta-Naphthol-alpha-Disulphonic Acid (Salt R).—This acid was treated in the same way as the monosulphonic acid, and naphthalenedisulphonic acid was finally obtained which yielded, on heating with caustic soda from 250°–280° C., a dihydroxynaphthalene, melting at 183°–184° C., and a naphtholmonosulphonic acid. The latter is identical with beta-naphthol- δ monosulphonic acid (naphthol-sulphonic acid F.). (This Journal 1887, 593.) The melting point of the dihydroxynaphthalene and the properties of the naphtholmonosulphonic acid render it probable that the naphthalenedisulphonic acid is identical with the one described by Ebert and Merz (Ber. 9, 592), and the constitution of the beta-naphtholdisulphonic acid is, therefore, either—

On the Constitution of Beta-Naphthylamine-Alpha-Sulphonic Acid. C. Immerheiser. Ber. 22, 412–413.

Of the seven possible beta-naphthylamine sulphonic acids four are known, two of which are considered to have their sulpho-groups in the α -position. One of those first prepared by Dahl and Co. (this Journal, 1885, 279–280) has, according to Cleve and Forsling (this Journal 1887, 721), the following constitution:—

The second acid, first prepared by the Bañische Anilin und Soda Fabrik, is believed to be—

The formation of the pyridinephenyleneketone sulphonic acid, however, proves that the amido and sulphonic groups are in different rings, as the following formulae show:—

Dahl's acid is believed to be

Therefore there remains for this acid only the formula—

—A. L.

On the Symmetrical Tetramidobenzene. R. Nietzki and E. Müller. Ber. 22, 440–450.

The constitution of the symmetrical tetramidobenzene is

Two amido-groups are either in ortho, para-, or meta-position to each other. Anhydrous acetic acid ought therefore to produce a soluble anhydro-base. This result, however, could not be achieved. When the hydrochloride of the base is mixed with dry sodium acetate and heated with anhydrous acetic acid a colourless body separates from this mixture after addition of water, with difficulty soluble in alcohol, easily soluble in hot glacial acetic acid, crystallising in long white needles, and melting at 285° C. The analysis gave figures for a tetracetyltetramidobenzene. On saponification with caustic potash, partial conversion into anhydride takes place, and only three acetyl groups are eliminated; if, however, hydrochloric acid be used instead of caustic potash, tetramidobenzene was formed. This proves the body to be a true tetracetyl derivative. The urea and thio-urea formed by the action of carbonoxychloride and carbon bisulphide on tetramidobenzene are greyish-white powders, insoluble in all solvents but caustic alkalis.

Quinoxalines and Azines from Tetramidobenzene.—Phenanthrenequinone acted only on two of the amido-groups, whilst the two others remained intact. Neither did other orthoquinones as naphthoquinone, rhodizonic acid yield well defined bodies of the double azine series. Ketones of the fatty series, as diacetyl, pyruvic acid, benzil, however, formed according to the conditions mono- or double quinoxalines.

If diacetyl be added in aqueous solution to a solution of tetramidobenzene hydrochloride and sodium acetate, a heavy precipitate consisting of orange-yellow needles separates at once. It is dimethyldi-amidoquinoxaline—

soluble in hot water, subliming between 130° and 140° C. with partial decomposition. Hydrochloric acid dissolves it with a red, sulphuric acid with a violet colour, which on dilution changes through red into orange. From alcohol it crystallises with one molecule of that compound. Acetic anhydride forms a compound which is either a diacetyl product or an anhydride derived therefrom.

Tetramethyldiquinoxaline.—

is obtained by heating dimethyldi-amidoquinoxaline with an excess of diacetyl. It is nearly insoluble in water, alcohol, and ether, soluble in hot aniline and crystallising from it in reddish-white plates, melting above 300° C., and subliming in crystalline plates, soluble in sulphuric acid with a bluish-green colour, turning blue on dilution.

Dimethyldihydroxydiquinoxaline.—

obtained by the action of pyruvic acid on tetramidobenzene, is soluble in caustic alkalis.

Diamidodiphenylquinoxaline.—

is formed by acting with benzil on tetramidobenzene. A precipitate separates, which when treated with alcohol of 50 per cent., dissolves this compound, whilst tetraphenyldiquinoxaline remains undissolved. Yellow plates, melting at 245° C. By the action of acetic anhydride a diacetyl compound is formed.

Tetraphenyldiquinoxaline.—

melting at 289° C., with difficulty soluble in glacial acetic acid, easily soluble in this solvent after addition of a few drops of hydrochloric acid, soluble in concentrated sulphuric acid with a blue colour, changing through red into orange, after dilution.

Oxidation products of Tetramidobenzene.—10 grms. of tetramidobenzene dissolved with 20 grms. of sodium acetate were dissolved in 200 cc. of water, heated nearly to boiling, and then a current of air passed through the solution for 2–3 hours. Green needles, the acetate of a new base, are thus obtained, soluble in water with a red colour, from which the base is precipitated by alkalis in brownish yellow plates, with difficulty soluble in hot water and alcohol. Purified by crystallisation from boiling aniline it forms long yellow needles containing aniline of crystallisation, which is removed by washing with alcohol. After solution in glacial acetic acid and precipitation with alkali, the substance was analysed. Its formula is $C_{12}H_{12}N_6$. The nitrate was found to be $C_{12}H_{12}N_6(HNO_3)_2 + 2H_2O$.

The base belongs probably to the class of the amidoazines or eurhodines discovered by Witt, and it is probably a tetramidodiphenazine—

It forms a tetra-acetyl compound, an orange yellow powder, nearly insoluble in all indifferent solvents. If the above be the correct formula, this compound ought to be able to form compounds with orthoquinones. This was proved to be the case with benzil and phenanthrenequinone, of which two molecules acted on one of the eurhodine. Phenanthrenequinone forms a compound containing 11 rings, of the formula—

—A. L.

On the Nitration of Naphthion Acid. R. Nietzki and J. Zübelen. Ber. 22, 451–452.

When naphthionate of soda is heated with acetic anhydride, an acetyl compound is formed, which when mixed with five times its weight of concentrated sulphuric acid and nitrated with the calculated amount of nitric acid forms a nitro-acetyl compound. The temperature was not allowed to rise above zero. On boiling with dilute caustic alkali the acetyl group is eliminated, and on addition of acids the free nitronaphthylamine sulphonic acid separates. Nitrous acid converts it into a diazo compound, capable of combining with phenols and amines. On reduction of the

nitronaphthylamine sulphonic acid a naphthylenediamine sulphonic acid is formed. The nitronaphthylamine sulphonic acid loses the sulpho group on boiling with dilute sulphuric acid, and forms a nitronaphthylamine melting at 119° C., identical with the one described by Beilstein and Kuhlberg. The sulphonic acid has therefore the constitution—

—A. L.

On Beta-naphthol-alpha-sulphonic Acid. R. Nietzki and J. Zübelen. Ber. 23, 453–456.

The authors produce alpha-naphthol from the beta-naphthylamine-alpha-sulphonic acid in the same way as Pfizinger and Duisberg (this Journal, 1889, 277).

The beta-naphthol-alpha-sulphonic acid forms with dilute nitric acid a nitro compound known in the trade as Bayers' "Croceine yellow." This is a dinitro-beta-naphthol-alpha-sulphonic acid. On reduction of this body a di-amido-naphtholsulphonic acid is obtained. Ferric chloride and other oxidising agents convert this body into an imido compound. The diamido-compound forms on addition of nitrous acid a diazo compound, one amido group only being diazotised—

—A. L.

On the Examination of Non-Basic By-products obtained from the Last Runnings of Aniline and Toluidine. C. Hell and Th. Roekenbach. Ber. 22, 505–514.

The authors examined two non-basic liquids obtained from the last runnings of the aniline and toluidine distillation by treating them, after saturation with hydrochloric acid, with steam. A distillate was obtained which yielded, in the case of the aniline product, after repeated distillation a fraction boiling between 258° and 263° C. It was however observed that it was not a uniform product. The oil was therefore oxidised with a solution of 5 per cent. of potassium permanganate until on boiling no more decolourisation of the oxidising agent took place. An oil remained and the liquid contained two acids, terephthalic acid and an acid of the formula $C_{10}H_{10}O_4$, which on account of the minute quantity obtained could not be further examined. From the oil crystals were obtained, which were recrystallised from ether and absolute alcohol. It contained two substances, one melting at 122.5° C., the other at 66° C. The latter could not be examined on account of its small quantity. The former contained sulphur, was soluble in concentrated sulphuric and nitric acids, and was reprecipitated by water. It was insoluble in alkalis. The compound is probably a sulphone. After removing these bodies from the oil it was distilled again, part boiling at 255°–259°, part at 259°–264°. The analysis of the lower boiling portion gave figures for the formula $C_{14}H_{22}$. On nitration with a mixture of sulphuric and nitric acids a nitro-compound, melting at 228° C., and on reduction an amido-compound were obtained. On treating the hydrocarbon with a mixture of four parts of concentrated and one part of fuming sulphuric acid a sulphonic acid was prepared.

In a similar way the product from toluidine was examined. It boiled between 240° and 270° C. On oxidation a mixture of volatile fatty acids, principally acetic acid, was obtained. The oil remaining after oxidation was rectified, the fractions boiling between 259–261.5° C. and 255°–259° C., the former being the larger. Analysis proved the formula $C_{14}H_{22}$, which is the same as that of the by-product from the making of aniline. No solid nitro-compound was formed on nitration.—A. L.

On Beta-naphthylamine-alpha-sulphonic Acid.

S. Forsling. Ber. 22, 619.

On diazotising beta-naphthylamine-alpha-sulphonic acid and treating the diazo-compound with cuprous bromide and concentrated hydrobromic acid, the corresponding bromo-naphthalenesulphonic acid was obtained, which was converted in the usual manner into a dibromonaphthalene melting at 75° C. This compound is either—

according to Meldola. A dichloronaphthalene analogously obtained by the author has, according to Erdmann, the chlorine atoms either in the same ring or in the position $\beta_1 = \alpha_1$. As these halogen derivatives were prepared in the same way, they must have the chlorine and bromine atoms in the same position, and the constitution of these halogen derivatives and of the naphthylaminesulphonic acid is therefore—

—A. L.

On Tetrahydro-alpha-naphthylamine. E. Baumberger and F. Bortt. Ber. 22, 625—634.

ALPHA-TETRAHYDRONAPHTHYLAMINE has the properties of an aromatic base. It combines with diazo compounds and forms colouring matters, distinguished from the analogous derivatives of alpha-naphthylamines in a certain way.

Phenylazo-alpha-tetrahydronaphthylamine is obtained by the action of diazobenzene chloride on the hydrochloride of the base. Steel-blue needles little soluble in water, benzene, chloroform, abundantly in glacial acetic acid and alcohol.

Sulphophenylazotetrahydronaphthylamine obtained from diazobenzenesulphonic acid and the hydro base. The acid is little soluble in water, more so in alcohol, with a dark orange colour. The sodium salt crystallises very beautifully.

Tetrahydronaphthylamine can be diazotised itself, and it also combines with amines and phenols.

Alpha-tetrahydronaphthylazo-alpha-naphthylamine.—Two bodies were obtained, one with difficulty soluble, the other easily soluble in alcohol. The latter melted at 135° C., forming brick-red needles, and was the desired compound.

Alpha-tetrahydronaphthylazoresorcinol forms brick-red plates, decomposing at 219° C., and soluble in concentrated sulphuric acid, alcohol, and alkalis with a dark claret-red colour.

The diazo-compound of the hydro base is capable of undergoing all the reactions characteristic of ordinary aromatic diazo bodies. Thus the amido group can be replaced by the hydroxycyan-, thiocarbonyl-, carboxamide-, carboxyl-, and hydrazine-groups, and also by hydrogen.

By the action of cuprous cyanide on the diazo compound Alpha-tetrahydronaphtholnitrile is obtained by Sandmeyer's reaction. The product of the reaction is a resinous substance, from which the nitrile is separated by steam. It is a colourless heavy oil, boiling at 277°—279° at 721 mm. pressure. As a by-product of this reaction tetrahydro-alpha-naphthol is formed. By the action of sulphuretted hydrogen on the nitrile Alpha-tetrahydronaphthoic thiamide is formed as a dark yellow oil.

Alpha-tetrahydronaphthoic Amide and Acid are obtained by saponifying the nitrile with alcoholic caustic potash at 160°—170°. On treating the resulting mixture with carbonate of soda the acid is dissolved whilst the amide remains. The latter melts at 182° C. and forms flat needles with difficulty soluble in cold, but with much more ease in hot water. The former crystallises in prisms, melts at 128° C., and is easily soluble in alcohol and boiling water, but with difficulty in cold water.

Alpha-tetrahydronaphthylhydrazine is formed by the action of the diazotised base on stannous chloride. White prisms, with difficulty soluble in water, easily in alcohol, ether, benzene, and hot petroleum spirit. It reduces Fehling's solution.

Tetrahydronaphthalene.—Experiments to prepare this body from the diazo compound met with but little success. But by acting with copper sulphate on tetrahydronaphthylhydrazine the compound was easily prepared. Five grms. of the hydrazine are suspended in boiling water, and a hot saturated solution of copper sulphate is gradually added, until the liquid remains blue. After acidulating, the hydrocarbon is distilled over with steam. It is purified by boiling it in etheral solution with sodium, and distils then at 205°—207° C. Colourless oil smelling intensely of naphthalene, absorbing bromine in chloroform solution, and decolourising potassium permanganate in a solution of dilute sulphuric acid instantly. Graebe and von Baeyer have already obtained tetrahydronaphthalenes, but whether they are identical with the one above described or not is still an open question.

The differences between alpha-naphthylamine and tetrahydro-alpha-naphthylamine and their derivatives are shown principally in their physical properties. The absorptive power for light of the coloured derivatives, whether in solution or on dyed silks, shows these differences remarkably well, and the authors explain the result of some spectrum examinations made by Althausse and Krüss.—A. L.

On the Action of Nitroso-bases on Phenylhydrazine.

O. Fischer and Leonard Waeker. Ber. 22, 622—625

NITROSO-BASES act on phenylhydrazine according to the following equations—

Nitroso-aniline Phenylhydrazine. Paraphenylenediamine.

Nitroso-dimethylamine. Paramidodimethylaniline.

The resulting products act like diazo compounds. When boiled, phenol and the original nitro-bases are formed, as well as the corresponding diamines: paraphenylenediamine and dimethylparaphenylenediamine, according to the equation—

Diazobenzene-nitroso-dimethylamine. Nitrosodimethyl-aniline. Amidodimethyl-aniline.

Nitroso-aniline hydrochloride and phenylmethylhydrazine acetate mutually react in aqueous solution, the mixture being well cooled. A yellow precipitate is formed, which, after crystallisation from alcohol, melts at 151° C. It exhibits corresponding properties to those of the above-mentioned products. Nitroso-dimethylaniline and phenylmethylhydrazine yield, under the same conditions, a splendid yellow compound melting after crystallisation from alcohol at 141° C. The constitution of these bodies is—

*Derivatives of Hystazarin.* A. Schoeller. Ber. 22, 683—685.

THIS isomeride of alizarin dissolves in alkali with a beautiful blue colouration. For its discovery and earlier investigation, see this Journal, 1888, 669.

Hystazarinbarium, $\text{C}_{14}\text{H}_6\text{O}_4\text{Ba}$, is prepared by mixing an alcoholic solution of hystazarin, to which a few drops of ammonia have been added, with baryta water, as long as a precipitate falls. It is a dark blue powder.

Hystazarincalcium, $\text{C}_{14}\text{H}_6\text{O}_4\text{Ca}$, prepared in a similar manner, is a dark violet powder. Hystazarinether, pre-

pared by heating together hystazarin, potash, and ethyl iodide, is a yellow, crystalline powder.

Hystazarindithylether, $C_{14}H_{16}O_2(O.C_2H_5)_2$, makes up the bulk of this precipitate. It melts at 160° — 163° C. *Hystazarinmono-ethylether* ($C_{16}H_{18}O_2$) may be precipitated from the alkaline liquid from the last named substance by adding an acid. It crystallises from alcohol in yellow needles melting at 231° — 240° C. The mono-ethylether dissolves in alkalis to a red solution; baryta and lime water have the same effect, especially on warming.

Hystazarin tetracetyloxanthranol is formed by boiling together hystazarin, sodium acetate, acetic anhydride, and zinc dust. From alcohol it crystallises in large colourless needles, melting at 217° — 219° C. Its formula is—

When the acetyl groups are removed according to Liebermann's method with sulphuric acid free from nitroso-compounds, a substance results crystallising from alcohol in small dark yellow plates. It contains somewhat less hydrogen than is necessary for oxanthranol; so that it is either oxanthranol partially oxidised to hystazarin, or a definite intermediate compound of the formula $C_{28}H_{18}O_8$.

On the Preparation of Meta-Nitrotoluene. K. Buehka. Ber. 22, 829—833.

THE author describes improvements in the preparation of meta-nitrotoluene according to the Beilstein-Kuhlberg method. Pure meta-nitrotoluidine, melting at 116° , is mixed with three times its weight of alcohol and the same amount of concentrated hydrochloric, or, still better, sulphuric acid. After cooling a slight excess of the theoretical quantity of sodium nitrite in saturated solution is added, and the mixture is carefully heated on the water-bath, after first standing for a short time. As soon as the evolution of nitrogen is finished the alcohol is distilled off and the meta-nitrotoluene driven over by a current of steam. The yield was 84 per cent. of the theoretical.

—A. L.

On some Derivatives of Paranitrometa-amidobenzene Sulphonic Acid and the Constitution of "Fast Yellow." F. Eger. Ber. 22, 847—852.

ON nitration of acetylmeta-amidobenzene sulphonic acid a para-nitro compound is obtained which is converted by reducing agents into a paraphenylenediamine sulphonic acid. The diazo-compound of the paranitrometa-amidobenzene sulphonic acid was prepared in the usual way. It crystallises in light yellow needles, exploding on heating, and containing one molecule of water. With Schäffer's β -naphtholsulphonic acid an orange colouring matter is formed. It combines also with β -naphthol and the solution of the azo-dye in caustic soda is coloured violet. By reducing paranitrometa-amidobenzene sulphonic acid with stannous chloride and hydrochloric acid paraphenylenediamine sulphonic acid is obtained in white crystals, soluble in water, with difficulty soluble in dilute, insoluble in absolute alcohol. The author proved further that the phenylenediamine sulphonic acid obtained from amidoazobenzene sulphonic acid or "Fast Yellow" is identical with that above described. According to the author's speculations "Fast yellow" has the constitution—

—A. L.

On the (1:1' or 1, 8) Naphthylenediamine. O. Hinsberg. Ber. 22, 861.

THE naphthylenediamine obtained from dinitronaphthalene and melting at 170° C. has the constitution—

It shows the properties of an orthodiamine. The author has, however, observed that with phenanthrenequinone it does not form an azine; however, the conditions may be varied.—A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

Wood Cloth. Eng. and Min. Jour. 47, 215.

MITSCHERLICH has applied the bisulphite process to wood for the production of a fibre which can be spun. Thin boards free from knots are cut into strips in the direction parallel with the grain, and are then boiled with a solution of sulphurous acid or bisulphite. The wood after boiling is partially dried in the open air or in drying rooms, to strengthen the fibre, which is originally very weak and tends to break with the slightest strain, but on drying becomes comparatively strong, and does not resume its very breakable condition on the addition of water. The damp masses on the frames are transferred on a travelling endless cloth to a pair of rollers, which may be plain or corrugated. Cutting of the fibre by the corrugations is prevented by passing the endless cloth over the lower roller and covering the upper one with canvas. The pressed masses are passed through other rollers, preferably to the number of six pairs. By the continued treatment the fibre becomes so pliable and separated that they may be employed directly for coarse filaments. For obtaining a perfect separation of the fibres without material deterioration, the boiled and pressed masses must be completely dried, and then combed in a manner similar to the combing of flax and cotton, but with the difference that the pins of the combing machine must be very strong. The separation of the extractable matter from the fibre produced by the boiling can be effected at any time, but preferably after the fibre has been spun into threads.

—G. H. B.

On the Theory of Dyeing. R. Hirsch. Chem. Zeit. 13, 432 and 449.

KNECHT has established beyond a doubt that the dyeing of animal fibre is a chemical process. Such being the case there is no reason why dyes alone should be regarded (in the restricted sense of the term) as capable of dyeing, unless all dyes have something in common, from a chemical point of view, which distinguishes them from other compounds. Nietzki has indeed endeavoured (Chem. d. org. Farbst., 2nd Edit.) to show that such a relationship exists. But the author considers this hypothesis untenable owing chiefly to the impossibility of including the nitro-bodies in such a system. Nietzki meets this objection with the statement that "nitrophenols probably have a similar constitution to the nitrosophenols, which latter are now generally represented as quinone oximes." But against this view several facts may be advanced: thus, three isomeric nitrophenols are known, which, as regards dyeing, differ only in strength; by the action of one mol. of nitrous acid on phenol, di- and trinitrophenols are also generated; moreover, nitroso bodies and quinones are never obtained in the meta position.

Experiments were made to ascertain whether wool has any affinity for organic substances. Some woollen yarn was boiled with 100 times its weight of water containing 1—2 per cent. of β -naphtholsulphonic acid R, calculated on the weight of the wool. By adding a drop of sulphuric acid, absorption took place more rapidly. The bath was not exhausted after prolonged boiling, but the larger portion of the sulphonic acid had united with the fibre, and could not be removed by boiling with cold water. This wool was now placed in a solution of diazobenzene or diazoxylene, and on adding a few drops of ammonia the dye developed perfectly. The shade and strength was found to correspond to wool dyed with 1 per cent. of scarlet or orange. It is interesting to observe that in presence of lime, baryta, or sodium carbonate formation of the azo-compound takes place very slowly. Caustic soda acts better, and ammonia most rapidly.

Colour reactions in acid solution were produced by immersing the wool, previously treated with naphtholsulphonic acid, in an acidified solution of sodium nitrite; the wool assumed the same light yellowish-brown shade that would be caused by boiling with a 2 per cent. solution

of nitrosonaphthol-sulphonic acid. After washing, the yarn was boiled with a slightly acid solution of ferrous sulphate, and thereby coloured green (Naphthol green of Cassella).

Naphthionic acid is fixed by wool both in acid and alkaline solution. The wool is coloured a dirty yellow-red, even if the purest crystallised product be employed, which points to a decomposition of the acid. But the change it undergoes must be slight, as after diazotising on the fibre an alkaline solution of β -naphthol dyes the wool the shade of roseellin. The property of combining so readily with wool is not shared by all bodies. Thus sulphanic acid is only absorbed in concentrated solutions. This new method of dyeing is of no technical importance, and the author does not intend to prosecute his researches further.

G. H. Hurst has recently stated that on boiling cotton, wool, or silk with benzidine sulphate, and then precipitating the solution with barium chloride, he obtains almost all the sulphuric acid contained in the sulphate, whence he concludes that benzidine has united with the fibre. It is obvious, however, that in either case, whether the benzidine remained in solution or not, he must have found the same quantity of sulphuric acid.—A. R.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Progress in the Colour Manufacturing and Dyeing Industries.
H. Erdmann. Chem. Ind. 12, 124—126.

THIS is a report upon the advance made, during the second half of the year 1888, in the technology of colour manufacturing, dyeing, and calico printing.

Regarding the *azo-dyes*, it is stated that an application in dyeing has been found for Carminaphte (β -naphthylamine-azo- β -naphthol), which hitherto has been used solely for making lakes or varnish stains. As the colour is easily removed from the fibre, Gilliard, Monnet, and Cartier are selling the dye for the purpose of colouring woollen yarns which are to be woven with yarns of a different twist, the various threads being then easily distinguished. The colour disappears on the fabric being heated above 80° C.

In contrast to this dye, on the other hand, certain *azo-dyes* exhibit a high degree of resistance, for example, the dye (sodium salt of naphthionic acid-azo- β -naphthol-disulphonic acid), known under the names of Fast Red D, Bordeaux S, Amarant, and Azo Acid Rubine, is characterised, even in its most delicate shades of pink, by its great resistance to light.

The demand for the *tetrazo* substantive cotton dyes still increases. Their use in the dyeing of pure and mixed woollen goods is extending, as shades fast to milling are obtained on the animal fibre. The dyes have also been recommended for dyeing cotton hosiery and paper pulp (this Journal, 1888, 843). In consequence of the extraordinary success of these dyes, endeavours are being made to substitute new bases for benzidine, tolidine, anisidine, &c.; Kalle and Co., for example, patenting diamidotolan, $\text{H}_2\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{C}(\text{C}_6\text{H}_4)_2 \cdot \text{NH}_2$, and A. F. Poirrier and D. A. Rosenstiel, diamidobenzil, $\text{H}_2\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CO} \cdot \text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{NH}_2$. The compound of diamidobenzil with α -naphthylamine can be again diazotised and combined with α -naphtholsulphonic acid. It is doubtful whether the diamines mentioned above can be prepared on an industrial scale. Other substantive dyes, whose natures have not yet been completely made out, have been prepared. The Mikado Brown of Leonhardt and Co. is made by reducing β -nitrotoluene sulphonic acid in alkaline solution with pyrogallol, gallic acid, tannic acid, sumac, &c., when a mixture of bodies is obtained, which dyes unmordanted cotton brown. Mikado Orange is also made in several shades. This dye is recommended for dyeing pure and mixed silk and for calico printing, on account of its fastness to light and soap; it has the peculiarity of not possessing any affinity for wool.

Of more importance is the discovery of a new class of substantive dyes which contain sulphur in combination;

the "Primuline" of Brooke, Simpson, and Spiller, Dahl and Co.'s "Chromogen," and Geigy's "Polychromine" are of this class. Primuline is not an azo-dye, but a diazotisable primary amine. On dry distillation it yields thiop-toluidine. Very similar, therefore, if not indeed identical, is the sodium salt of thio-*p*-toluidinesulphonic acid patented by Dahl and Co., which, like primuline, dyes a bright yellow on unmordanted cotton. The yarn dyed yellow and rinsed is worked in a diazotising bath of nitrite of soda strongly acidulated, and then in dilute alkaline baths of the naphthols or naphthol-sulphonic acids, when deep red (ingrain red) shades are produced; the hydrochlorides of α -naphthylamine and *m*-phenylenediamine give brown, while β -naphthylamine and β -naphthylaminesulphonic acids give yellow-reds and oranges; the shades are fast to milling and fairly fast to light.

To the Badische Anilin und Soda Fabrik is due the honour of introducing the derivatives of *m*-amidophenol as dyestuffs. The phthalicins or rhodamines of this group surprised those interested by the delicacy and fastness of their shades, and now another member, Nile Blue, is much admired for its beauty and purity of tint. This dye belongs to the oxazines. It is manufactured from nitroso-dimethyl- (or diethyl-) *m*-amidophenol and naphthylamine, and has the constitutional formuln—

It dyes cotton mordanted with tannic acid and tartar emetic, and surpasses methylene blue in brightness of shade. Another rival of Methylene Blue is K. Oehler's Ethylene Blue. It differs from Methylene Blue in possessing less resistance to steaming and treatment with alkalis, properties due to its containing some of the Methylene Azure described by Berthelsen.

Amongst the *Indulines* the Paraphenylene Blue of Dahl and Co. is much heard of. The most valuable property of this dye is that it can be darkened on the fibre by oxidation with chromic acid, the shades so produced being exceedingly fast.—E. B.

PATENTS.

Improved Machine for Dyeing Yarns. T. Wolstenholme, Camden, New Jersey, U.S.A. Eng. Pat. 2060, February 5, 1889. 8d.

A DYE-TANK of suitable shape and construction is provided on its outside with a main driving shaft. At each end of the shaft there is fixed a crank arm pivotally connected by rods with beams mounted so as to swing on top of the tank at each end. The inner ends of the beams support a yarn-stick frame in such a manner that the frame can be easily attached to, or detached from, the same.

The frame is preferably rectangular in shape, and in the upper part of it longitudinal beams are placed to hold the yarn-sticks, which rest in notches in the beams. The lower part of the frame is provided with beams which slide vertically, and which have notches in them for receiving yarn-sticks.

The hanks of yarn are placed on the sticks and then on the frame whilst the latter is out of the tank. Then the frame is lowered into the tank, and an up and down swinging motion imparted to it by the mechanical arrangements which are described in detail in the specification, with drawings.—E. B.

Improvements in Sanitary Materials or Preparations for Preventing the Decomposition and Deterioration of Sizes and similar Finishes for Fabrics and the like, and for preventing the Access of Infectious Disease. R. Hannan, Glasgow. Eng. Pat. 3159, February 22, 1889. 4d.

See under XVIII. C., page 411.

VII.—ACIDS, ALKALIS, AND SALTS.

On Existing Tables for Aqueous Solutions of Ammonia at Different Specific Gravities. H. Grüneberg. Chem. Ind. 12, 97—100.

THE growing application of ice-machines has created a large trade in concentrated solutions of ammonia. The tables of Ure and Carius, which are mostly used, differ so widely as to be no longer suitable for trade purposes, and the present investigation was undertaken with a view of supplying the urgently-felt want of more trustworthy tables. The analytical determinations were performed partly by estimating ammonia as ammonio-platinum chloride, and partly by titration, the former method proving more accurate than the latter. Both Davy and Dalton at one

time investigated the same subject, and stated their results in a tabulated form. However, they overlooked the fact that an alteration of volume takes place in mixing concentrated solutions of ammonia with water, and their results are therefore wrong. Ure and Meissner took the alteration of volume into consideration, and although their table approaches more nearly to actual facts, their analytical determinations lack the accuracy required at the present day. Carius and Wachsmuth later on tried to improve on the work of their predecessors, but they unfortunately worked at different temperatures. The latest investigation is published by Lunge and Smith in 1883. In the higher degrees of concentration their results, which were calculated by interpolation, lie between those of Carius and Wachsmuth, whereas Grüneberg's figures, obtained by actual analyses with platinum chloride, agree with those of Wachsmuth. Grüneberg's table is as follows:—

Specific Gravity at 15° C.	Ammonia. Percentage by Weight.	Specific Gravity at 15° C.	Ammonia. Percentage by Weight.	Specific Gravity at 15° C.	Ammonia. Percentage by Weight.

291

As already mentioned, the different tables cannot be exactly compared with each other owing to the different temperatures used by the various investigators, and to different statements referring to varying percentages and specific gravities. Carius' table, for instance, states specific gravities with uniformly increasing percentages, whereas Wachsmuth's table states percentages with proportionally increasing specific gravities. A more convenient and more general comparison between the different results is obtained by representing them graphically, as shown in the diagram.

In conclusion, a strange and little-known phenomenon is mentioned, which may be observed on neutralising an ammoniacal solution with acid. If litmus solution be used as an indicator, it appears that there is a difference whether the acid is added to the ammonia or whether ammonia is added to the acid. If a standard acid solution be added to ammonia, the litmus solution indicates the neutral point sooner than if ammonia be added to the same standard acid. The use of litmus solution as an indicator with ammoniacal solutions is therefore unsafe; red litmus paper acts more satisfactorily, whereas methyl-orange can be highly recommended.—S. H.

On Magnesium Chloride. K. W. Jurisch. Chem. Ind. 12, 100—103.

THIS article is a criticism of Eschellmann's paper (this Journal 1889, 190—193), which according to Jurisch contains several mistakes. Eschellmann's calculations are somewhat false, and therefore cause wrong conclusions. The right method of calculation is thus:—If

W = grms. of water in magnesium chloride used,

C = grms. of chlorine driven off as hydrochloric acid,

G = loss of weight in grms.,

x = grms. of water driven off undecomposed,

y = grms. of water in residue,

and if the decomposition of magnesium chloride by means of steam take place according to the equation—

so that 18 grms. of water are decomposed for every 71 grms. of chlorine liberated, we obtain the following equations:—

$$\text{I. } G = x + C + \frac{2C}{71} = x + \frac{73C}{71} \text{ or } x = G - \frac{73C}{71}.$$

$$\text{II. } W = x + y + \frac{18C}{71}.$$

If we substitute the value of x into the equation II., then

$$y = W - G + \frac{55C}{71}.$$

The author further objects to Eschellmann's statement of the formation of a distinct chemical compound of the formula $2 \text{MgO} \cdot 4 \text{MgCl}_2 + 3 \text{H}_2\text{O}$, if magnesium chloride be heated between 250° and 350°C . The mass is not a chemical compound at all, but a mixture, the composition of which agrees only temporarily with that formula. As a matter of fact, another of Eschellmann's experiments gives a body which has the formula $3 \text{MgO} \cdot 7 \text{MgCl}_2 + 4 \text{H}_2\text{O}$. Eschellmann's calculation of the cost price of potassium chlorate is also open to objection, as he takes no cognisance of the fact that the price of hydrochloric acid is subject to fluctuations.

In reply to these remarks, Eschellmann admits his mistake as to calculation, but shows that the mistake is so small as to alter his results only in the first decimal place. So slight a mistake cannot upset his conclusions. He yet maintains the formation and existence of a chemical compound of the formula $2 \text{MgO} \cdot 4 \text{MgCl}_2 + 3 \text{H}_2\text{O}$. It is not permissible to take one experiment out of a large number and bring it forward as an argument against the formula. In investigations of this kind every experiment must be considered when drawing conclusions therefrom. Schloesing, in treating magnesium oxychloride with dry hydrochloric acid, obtained a body of a similar composition, and if magnesia, which contains small quantities of

potassium chloride, be chlorinated at high temperatures, the chlorination is arrested as soon as a body of the formula $\text{MgO} \cdot 2 \text{MgCl}_2$ is formed. All these facts speak in favour of Eschellmann's view. He still holds his calculation of the cost price of potassium chlorate to be thoroughly correct, and thinks Jurisch's recommendation of manufacturing potassium chlorate by the Hurter-Deacon process altogether impracticable. In the latter case 33½ tons of hydrochloric acid, containing as impurities copper, arsenic, iron, chlorine, and sulphuric acid, would be recovered as a by-product for every ton of potassium chlorate, and it is not an easy matter to find a regular sale for such large quantities of an impure acid.—S. H.

On the Solubility of Salts. H. Le Chatelier. Compt. Rend. 108, 565—567.

ROOZEBOM has stated that at a given temperature the same salt may have two distinct coefficients of solubility. Thus, he maintains that the hydrate of calcium chloride, $\text{CaCl}_2 \cdot 6 \text{H}_2\text{O}$, at temperatures below its melting point, $30 \cdot 2^\circ$, presents a curve of solubility formed of two distinct branches, which unite at the melting point of the hydrate. The author shows that the above is opposed to the general laws of chemical equilibrium formulated by himself on different occasions. Were Roozeboom's conclusions correct, the heat of dissolution would have to be infinite, which, of course, is out of the question. Actually, the curve shows an angular point, but this is due to the existence of two curves, which meet at the melting point of the salt. One represents the solubility of the hydrate $\text{CaCl}_2 \cdot 6 \text{H}_2\text{O}$, in water, the other a mutual solubility of the same hydrate and the anhydrous salt, or one of its lower hydrates.—A. R.

PATENTS.

Improvements in the Manufacture of Chromates. W. J. A. Donald, Glasgow. Eng. Pat. 5086, April 5, 1888. 4d.

IN the manufacture of chromates from chrome ore, a waste product is obtained, commonly called chrome waste, which contains about 60 to 70 per cent. of lime and up to 5 per cent. of chromic oxide, which has escaped decomposition in the chrome furnace. The inventor has found that by roasting this waste residue, it may be repeatedly used in lieu of fresh lime in making up the charges for the chrome furnace. Thus, all the chromium compounds, along with any alkalis contained therein, are practically recovered, and contribute materially to the economy of the process.—S. H.

Improvements in Means to be Employed in the Production of Solutions Containing Sulphurous Acid or its Salts.

I. S. and J. T. McDougall, Chadderton. Eng. Pat. 5212 April 7, 1888. 11d.

THE object of this invention is to effect the absorption of sulphurous acid by a solution, the gas not being under pressure. This is accomplished by conveying the sulphurous acid gas through a series of closed oblong vessels, which are fixed in a horizontal or inclined position, supported in such a manner that they can be rotated. The diagram shows in plan an apparatus arranged according to this invention. A are three rotary vessels and A² one stationary vessel. Attached to the interior of the vessel A are projections a, intercepted by transverse partitions a², with central apertures a³, to allow of the passage of the gas and liquid through the vessel. These projections, as they move, carry with them a portion of the liquid and shower it upon the gas, whilst the transverse partitions prevent an immediate flow of the liquid from one end to the other. The level of the latter is such as to leave a passage for the gas above the liquid. D are connecting pipes for the passage of the gas and liquid from vessel to vessel. The liquid to be treated is stored in the tank D², and its flow is regulated by a tap. A continuous current of sulphurous acid enters the apparatus at E, and meets successively a shower of liquid in the

rotating vessels, the liquid, as will be noticed, travelling in a direction opposite to the current of the gas, and when it leaves the apparatus is obtained in a condition most highly saturated with the gas. The course of the gas is shown by the dotted arrows, and of the liquid by the full arrows.

Improvements in the Production of Alkalis and Alkaline Salts from the Slag resulting from the Manufacture of Ingot Iron and Steel. T. Twynam, London. Eng. Pat. 5386, April 11, 1888. 6d.

See under X., page 399.

Manufacture of an Ammonia Carbonate applicable as Baking Powder. R. E. Chatfield, Sewardstone. Eng. Pat. 6151, April 25, 1888. 6d.

AMMONIA is first prepared by heating ammonium sulphate with magnesia in excess, to 240° F. The ammonia passes off, and is "condensed in aqueous solution." Carbonic acid gas, in the proportion of 19 parts to 17 parts of gaseous ammonia, is then admitted into the vessel containing the aqueous ammonia, and the whole allowed to crystallise. The crystals are then treated with a further quantity of carbonic acid gas, when they become friable and inodorous.

Process for the Conversion of Chloride of Calcium into Chloride of Magnesium and Carbonate of Lime by Means of Oxychloride of Magnesium and Carbonic Acid. G. Borsche and F. Brünjes, Leopoldshall-Stassfurt, Germany. Eng. Pat. 7046, May 11, 1888. 4d.

BURNT or precipitated magnesia is treated with magnesium chloride to form the oxychloride. This is then mixed with the chloride of calcium liquors and carbonic acid gas passed in with the formation of calcium carbonate and magnesium chloride.—S. G. R.

Improvements in the Construction of Apparatus for Making Bisulphites or other Compounds used in the Treatment of Wood Pulp and other Fibrous Materials and the like. I. S. and J. T. McDougall, R. K. Hartley, and T. Sngden, Oldham. Eng. Pat. 7060, May 11, 1888. 11d.

THE object of this invention is the absorption of sulphurous acid by a solution, without using a contrivance for forcing the gas through a depth of liquid. A series of vertical towers is provided, as to interior arrangement, with perforated plates. These towers are made with coned bottoms terminating in pipes, which are fitted with a pumping device. The pipes extend upwards, and open into the top of the tower. The solution to be treated is run into the coned part of the last tower, and the pump conveys it to the top, whence it gradually descends through the plates to the bottom. The different coned bottoms are connected by pipes, so that the liquid may flow from one tower to the next. The gas enters at the bottom of the first tower, and after rising upwards, escapes from the top to the bottom of the next, and so on. The gases and liquids are thus passed in opposite directions, the number of towers being regulated according to the degree of saturation required.—S. H.

Improvements in Metallic Drums, and Lids therefor. R. Jackson, Rainhill. Eng. Pat. 7317, May 17, 1888. 6d.

A DRUM for containing caustic soda or other like substances has an aperture in the drum-head having inward-turned edges. The lid is made with one or more projecting clips and guide-pieces, by which it is readily and securely applied to the drum head. The lid has also an aperture on one side for the insertion of a wrench, by which it may be easily prised off.—E. S.

Improvements in or relating to the Manufacture of Vinegar. E. Barbe, Paris, France. Eng. Pat. 17,549, December 1, 1888. 11d.

THE invention consists of apparatus for automatically feeding the acetifying arrangement with liquor at intervals by means of feed vessels containing siphons brought into action by the periodical compression or rarefaction of air. For details, the specification and four sheets of drawings must be referred to.—J. M. H. M.

Improvements in Apparatus for Evaporating Brine, and for similar Purposes. H. H. Lake, London. From J. M. Dunan, Silver Springs, Wyoming, U.S.A. Eng. Pat. 785, January 16, 1889. 8d.

See under I., page 380.

Improvements in the Manufacture of Salts of Alumina. E. Augé, Montpellier, France. Eng. Pat. 1189, January 22, 1889. 4d.

THE object of this invention is the manufacture of salts of alumina free from iron. Finely-pulverised bauxite is treated with sulphuric acid. After the reaction is finished, usually after five hours, the mass is diluted with water and run off into a settling-tank. If the whole of the iron be not converted into peroxide, some oxidising agent is added. It is important that no free sulphuric acid be present. A certain quantity of bauxite, such as that employed in the first stage, is then introduced into the aluminium sulphate solution, along with some potassium salt, the quantity being regulated according to the quantity of iron to be precipitated. The solution is energetically agitated, allowed to stand for a time, when the iron is slowly eliminated. At the end of about 25 days the amount of iron is quite inappreciable.—S. H.

Improved Manufacture of Porous Surfaces for the Absorption of Liquids and Gases. F. H. Glew, London. Eng. Pat. 4609, March 26, 1888. 6d.

THE porous surfaces are made by coating gutta-percha sheet with fine pieces of coke, pumice, or sponge. The pieces of coke or pumice, after being properly sifted, are placed on an iron plate heated to such a temperature as to soften the gutta-percha when pressed upon it by a pad of leather or cloth. The particles of coke then adhere to and become embedded in the surface of the gutta-percha sheet. Such surfaces, when saturated with a liquid, are used to charge the air or any gas brought in contact with them with the vapour of the liquid. When it is necessary to carry on the evaporation of the liquid at a temperature which would melt the gutta-percha, the surfaces are made of porcelain or stoneware coated with particles of coke or pumice.—H. S. P.

Improvements in the Manufacture of Porous Artificial Stone for Use as Indestructible Wicks or Burners for Lamps, or as Filter Partitions and the like. W. D. Gooch, F. H. Varley, and F. B. Lidstone, London. Eng. Pat. 5214, April 7, 1888. 6d.

THE ingredients employed to make the porous stone may be used in the following proportions by weight:—12 parts of fine sand, 4 parts of asbestos, $1\frac{1}{2}$ parts of borax, $2\frac{1}{2}$ parts of red lead or litharge. These proportions may be varied, and clay, rotten stone, emery, or corundum may be used instead of the sand and asbestos, and glass and suitable flux instead of the borax and lead oxides.

The ingredients are first thoroughly mixed, reduced to a fine powder, and then heated to incipient fusion, allowed to cool, and again reduced to powder. This powder is packed into moulds of a suitable shape and heated to a bright red heat. The particles of powder are amalgamated and a stone of fine texture and of high degree of capillarity is produced.

—H. S. P.

An Improved Process for Painting on Glass, Porcelain, Tin, and the like. W. Michaelson, London. Eng. Pat. 338, January 8, 1889. 4d.

See under XIII., page 403.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

Turbid Glass. F. Knapp. Chem. Zeit. 13, 388.

NORWEGIAN felspar, when smelted, gives a glass which is not transparent, while at the same time it does not resemble milk-glass. Microscopic examination shows the opacity to be due to the existence in the glass of a large quantity of small bubbles. By mixing lime with the felspar, however, the character of the glass is completely altered, the change varying with the quantity of admixed lime. Small additions of lime have the effect of producing a clear, colourless glass perfectly free from bubbles; a further addition produces rich opalescence, whilst a still further addition gives an opaque glass without opalescence, but possessing a good surface. These facts show, the author points out, that the milkiness in this glass is in no way due to phosphates or fluorine compounds.—T. L. B.

PATENTS.

A Special Disposition of Furnace for Annealing Thick Plate Glass by letting it Cool gradually and by Annealing it with Gas Heat. D. Gilles, Marches-les-Dames, Belgium. Eng. Pat. 1449, January 31, 1888. 8d.

THE annealing furnace is a construction of masonry about 97 ft. long and of a width regulated by the length of the plates to be annealed. These latter are introduced direct from the casting table into one end of the furnace, which may be heated by special fires (gas or otherwise) or by the waste heat from the melting kilns. Plates of $\frac{1}{8}$ in., $\frac{3}{16}$ in., $\frac{1}{4}$ in. thickness can be annealed in 1, $1\frac{1}{2}$, and 2 hours respectively.—A. R. D.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Influence of Frost on Portland Cement. Böhme. Mittheil. d. Königl. techn. Versuchs. 1889, 43—49.

EXPERIMENTS were made on 10 samples of cement in the following directions:—

I. The general properties of the samples. II. Their strength in tension and compression, alone and in admixture with three times their weight of normal sand after seven and 28 days, with and without an exposure for a part of that time to a temperature of -12° C. to -15° C. III. Their power of enduring attrition. Tests were made on the pure cement and on mixtures of 1 part by weight of the cement to 1, 2, 3 and 4 parts by weight respectively of normal sand, all of which, including the cement alone, were subjected to the following conditions during setting:—(a), exposed to moist air; (b), left 24 hours in the air, then transferred to water; (c), left 24 hours in the air, then exposed for 20 hours to a temperature of -12° to -15° C., placed in water at 18° C. for four hours, again frozen for 20 hours, thawed once more for four hours, and left for the rest of their allotted time under water.

The attrition to which they were subjected was obtained by the use of a revolving iron plate supplied with a fixed quantity of emery powder, loaded with a constant weight, and run for a given number of revolutions. The results are recorded in very lengthy tables, and the conclusions to which they point are—

(1.) That the chief effect of the frost is to retard the setting of the cement, causing it to remain soft, and reducing its tensile strength and resistance to compression.

(2.) That this retardation has little permanent effect, the cement becoming nearly equal to the unfrozen specimens after the lapse of 28 days.—B. B.

PATENTS.

Improvements in certain Fire-resisting Materials. F. M. and D. D. Spence, Manchester. Eng. Pat. 5917, April 20, 1888. *Sd.*

THE invention consists in forming into solid compact cakes a mixture of sulphate of alumina or "aluminoferric" (a commercial sulphate of alumina containing a notable proportion of ferric sulphate) and sawdust. These cakes are to be used for filling the hollow jackets of fire-resisting safes, boxes and chests, the cavities of fire-resisting doors, &c., instead of the packing powder of granulated alum and sawdust that is usually used.—H. S. P.

Improvements in Waterproof Roofing Material. E. Edwards, London. From F. Meyer, Ostritz, Germany. Eng. Pat. 18,708, December 21, 1888. *Ad.*

WOVEN fabric of jute, flax, or other spun material is soaked in a solution containing 1 part of tungstate of soda and 10 parts of sulphate of ammonia to 100 parts of water, to render it "sufficiently incombustible." It is then dried and asphalted by passing through a heated mixture of Trinidad asphalt, tar, oil, and sulphur, in the proportions, by weight, of 1,000 of asphalt to 400 of tar, 10 of oil and 3 of sulphur. Any superfluous of asphalt mixture is removed from the surfaces of the fabric by passing it, whilst still hot, through a heated stripping frame. It is then sanded on both sides, pressed between iron rollers, and cut into suitably-sized pieces.—H. S. P.

X.—METALLURGY, MINING, Etc.

An Investigation of the Construction of the various kinds of Cupolas that have been used for the Melting of Pig-Iron. M. A. Gonvy, Jr. *Mémoires et compte rendu des travaux de la Société des Ingénieurs Civils.* Paris, 1887, 723—766.

THIS is a long historical paper giving illustrations and short descriptions of a large number of cupolas, from the early "calabash," consuming 40 lb. of coke for every 100 lb. of cast-iron melted, down to the modern forms of cupola with a consumption of about 6 to 15 lb. of coke for the same quantity of metal. There are 43 drawings in the paper. Among the early kinds of cupolas were those having superposed tuyeres for the purpose of accumulating large quantities of iron for large castings. Modifications were also introduced for the use of a hot blast and for the utilisation of the waste heat at the throat for producing the same. These, however, have been gradually abandoned as it was found that no economy of fuel took place. The hot blast only served to increase the temperature of the zone of fusion, with the formation of a larger quantity of carbon monoxide in the waste gases. Drawings are given showing suggestions as to the position, shape and size of the wind box, from the Woolwich cupola, in which it surrounded nearly the whole furnace the air entering at top, to that which possessed simply an annular chest round the tuyeres.

The influence of the profile of the furnace is next entered into, and the cupolas of Gerhardt, Ireland, and the St. Gervais foundry are described, in each of which the cylindrical section is replaced by one showing bosses and a narrow crucible part, after the style of the ordinary blast furnace. Gerhardt also supported the upper part of his furnace on angle irons to facilitate repairs to the lower

portions. Other improvements have been introduced for the purposes of cooling the walls, equally distributing the blast, &c. In the Gmelin cupola, water circulates in an envelope of plate iron from the bottom to the top of the furnace. Lawrence places, immediately above the principal tuyeres, three rows of orifices of rectangular section, each row being narrower than the one below it, for the purpose of obtaining an equal distribution of the blast. Bocard aims at the same object by a continuous slit round the circumference of the cupola between the upper part and a movable crucible. Krigar in his early forms ensures regular distribution of air by an annular box with vertical rectangular orifices, and collects the melted iron in a separate crucible. Herbertz also employs an annular tyere which can be adjusted according to height of fused material. He also produces a forced draught by means of an ejector. (See this Journal, 1886, 451.)

There is an objection to the Herbertz cupola in the fact that the waste gases contain a large amount of oxygen. Analyses of gases from the tops of Krigar and Ireland systems range from 12.4 to 16.5 per cent. in volume of CO_2 , 2.5 to 11.7 per cent. of CO, and oxygen nil, while the Herbertz shows 10.7 to 11.5 per cent. of CO_2 , 0.0 to 3.4 per cent. of CO, and 6.7 to 8.2 per cent. of oxygen, which means that 37.7 cubic feet of useless air is drawn in for every 100 cubic feet which traverse the furnace. Woodward employs a steam ejector over the centre of the throat of the eupola and has a side charging hopper, but the furnace seems to give irregular results, probably from the same cause as the Herbertz.

A new form of Krigar cupola with a forced draught is shown in Fig. 1. This furnace possesses a separate crucible for the melted iron, over which part is a chimney with a steam ejector, by which the air is drawn through the tuyeres downwards, and the products of combustion, passing over the melted iron, keep up the temperature of the metal. The disadvantage of this system apparently is that the charge is not heated until it reaches the zone of fusion, but on the other hand it is maintained that there is less waste of iron and that there is less decarburisation as the metal is not subjected to the oxidising action of an ascending current of air.

The next series of furnaces are those which have been constructed with a view of ensuring complete combustion of the carbon. Voisin appears to have been about the first to give attention to this matter. He placed a second row of tuyeres above the zone of fusion on a level with the height at which most carbon monoxide was produced, with the idea of burning it into carbon dioxide again, and so creating a second zone of fusion. Good results were obtained, and cupolas on this principle were built at Angers, and by Hamelins and Stewart, the latter of which possessed three rows of tuyeres, the top row being provided with regulating valves. But above this second zone and even the third, carbon monoxide becomes again formed, although to a less extent than before. To obviate this, Norris constructed a furnace in which the tuyeres were not in a horizontal plane but were placed in helical form around the eupola, so that the air was introduced at different heights. This arrangement, however, did not give good results, and entailed a considerable loss of iron.

In the Greiner and Erpf cupola, built somewhat after this principle, the difficulty seems to be overcome, and further good results appear to be attained. This eupola possesses a horizontal row of tuyeres near the base, so as to keep the zone of fusion low as in the usual forms, and from 50 to 60 inches above this commences a series of small tuyeres arranged in a helix, which terminates some distance higher up. These small tuyeres supply the air to burn the carbon monoxide at different levels, and the heat which is produced, being thus distributed, is insufficient to raise the coke to a red heat so that no further reduction of the carbon dioxide takes place. In the early furnaces these small tuyeres were supplied from a helical wind box. The more modern forms provide for the regulation and control of the blast through them by connecting each one separately by a vertical tube with the wind chest of the lower tuyeres. Fig. 2 illustrates

Fig. 1.

Fig. 2.

this cupola. Each small tuyere possesses a glass back by means of which the necessity of admitting air can be readily ascertained. The waste gases are very cool and contain very little and sometimes no carbon monoxide. There are, however, no analyses obtainable. The theoretical amount of coke necessary to melt 100 lb. of iron is

four pounds. An instance is given in which this cupola melted 100 lb. of iron with three pounds of coke, the apparent anomaly being explained by the fact that the carbon monoxide produced from the coke required to heat the bed is utilised. The following table shows the comparative results of this system with some others:—

	Chisnyoviz Cupola.		Westphalia Union Society.		Greiner and Erpf, Société de Construction à Prague.	Greiner and Erpf, Fonderie de Schlick, Budapest.
	Old System. Two Tuyeres.	The same changed to Greiner and Erpf.	Common Ireland Cupola.	The same changed to Greiner and Erpf.		
Number of charges	207	136	Mean of 3 months.	Mean of 7 heats.	414	213
Weight of iron per charge in lb.....	882 to 1,102	882 to 1,102	882	882
Weight of coke per charge in lb.	74 to 119	22 to 33	35	35
Coke for melting in per cent. of iron	9.46	2.80	9.65	5.26	3.95	3.88
Total coke (bed included) in per cent. of iron	12.28	6.27	15.71	9.18	5.97	6.68

Gas cupolas have been constructed in various forms, such as the Dufréné (see this Journal, 1882, 411), which is furnished with a gas producer; the Besson (see this Journal, 1882, 410), which is a kind of huge blowpipe, and the Bramhall, wherein the regenerative system was suggested on the supposition that the waste gases were at a higher temperature than they should be. Krigar patented a cupola with two shafts, one closed and containing coke, the other open and in which the pig-iron is placed. The air is forced through the lower portion of the closed shaft containing the incandescent coke, and rises through and melts the iron in the open shaft.

Riley adapts the gas producer to the reverberatory and cupola furnaces combined for the production of open hearth steel. Fig. 3 illustrates this arrangement. Pig-iron and steel scrap is charged without any solid fuel into the

cupola, and is melted there by the heat from the reverberatory. The metal runs down on to the bed of this latter and there becomes converted into steel. The time of open hearth operation is accelerated 10 per cent., due to the fact that the oxidation of the carbon and silicon takes place in the cupola. Siemens mentions experiments with this furnace, in which coke was charged into the cupola with the iron, but they were not successful because decarburisation did not take place in the cupola, but only in the reverberatory under a layer of slag. The consumption of fuel in the gas producer was reduced to 7.2 per cent. of the pig iron charged, and the product per hour was two tons.

Other systems of cupolas are mentioned, wherein the object has been to produce metal of a required composition. The Batty, the Voisin-Bichon, the Herdlitschka, in which

Fig. 3.

the regenerative system is proposed, and the Ibbruger where the gas is directed downwards after the principle of the Krigar. Lastly, the Krupp system, intended specially for the purification of iron. The iron mixed with oxide of iron is melted in an upper eupola and runs down into the purifying eupola, both of which are made of neutral bricks,

with a basic or neutral lining. The oxide of iron may or may not be mixed with lime or oxide of manganese. The silicon, manganese, sulphur and phosphorus are in great part removed. The results obtained in a small temporary apparatus were the following :—

—	C.	Si.	Mn.	Cu.	P.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Impure Iron	3.730	0.470	3.500	0.250	0.600
Purified iron. 1st trial	3.000	0.004	0.128	0.250	0.136
„ 2nd „	3.400	0.005	0.210	0.250	0.187
„ 3rd „	3.400	0.002	0.470	0.250	0.210

The cinder obtained from one of these contained P_2O_5 , 5.28 per cent.; MnO , 26.30 per cent.; FeO , 41.28 per cent.; SiO_2 , 17.60 per cent.; CaO , 1.46 per cent.; MgO , 0.36 per cent.; and S, 0.66 per cent.

In conclusion the author states that the result of this study shows that the lowest net cost of melting iron in a eupola has been obtained in the Greiner and Pipf forms,

and further, that the employment of blast heated by the waste gases, the substitution of a natural or a steam exhaust draught for a pressure blast, the injection of various materials at the tuyeres or otherwise do not appear to be attended with economy. Finally, the following table is given, showing the dimensions, particulars, working cost, &c., from practical results of 33 different eupolas :—

Occurrence of Gas in Iron Tubes Rolled by the Mannesmann Process. Finkener. Mitteil. d. Königl. techn. 1889, 41—43.

By the Mannesmann process iron tubes are rolled from a solid cylinder of the metal by dint of forcing the surface of the cylinder to increase so largely that to supply the necessary material rupture occurs and a cavity forms which eventually becomes the interior of the finished tube. This cavity is not vacuous as might be expected, but contains gas. In order to obtain this gas for analysis, recourse was had to the apparatus figured in the accompanying block. It

having been ascertained that the tube to be examined was free from cracks by exposing it under water to a vacuum, a place on it was filed nearly through, and the testing repeated. In the figure, *a, b* is a portion of a steel cylinder of such radius as to fit snugly saddle-wise on the iron tube; between the two is a piece of sheet-rubber to make the joint airtight, and they are bound together by rubber bands. *a, b* has the upright tube *d* screwed and sweated into it, and this contains a plunger *g* passing through a gland *h*, the packing of which consists of a piece of rubber tube. The tube *l*, carrying a stop-cock, serves to make or sever connexion with a mercury pump. The apparatus being in position, *g* is removed, a cork-borer inserted in its place, and a disc of rubber cut out by it from the sheet between *a, b* and the iron tube; *g* is then put back, the whole apparatus exhausted and left for an hour to see if it be tight. The cock is then closed, and the iron tube pierced by a few blows on *g*. The cock is now cautiously opened, the gas existing in the iron tube pumped out, collected and analysed. The iron tube is afterwards allowed to fill itself with air under ordinary pressure, its contents pumped out, measured, and its volume thus ascertained.

Of the two tubes thus examined, the first had a volume of 104.4 cc. and contained 12.51 cc. of gas; the second, of 123.4 cc., and held 9.11 cc. of gas. After disproving the existence of carbon dioxide, hydrocarbons, and air, in the gas from the first tube, the experiment was spoiled. An analysis of the gas from the second tube showed it to consist of 99.0 per cent. of hydrogen, and 1.0 per cent. of nitrogen.

The iron of which the tube was made contained—

	Per Cent.

—B. B.

Nickel Ores in the Ural. M. Stenbok. Chem. Zeit. 13, 430.

IN the neighbourhood of Ekaterinburg, in the Province of Perm, an apple-green clay containing nickel was long ago discovered. It contains a very pure hydrated nickel and magnesium silicate, and is free from cobalt, sulphur, and arsenic. 330,000 puds (1 pud = 40 lb.) of this ore have of late years been treated. By the metallurgical process a nickel containing 97 per cent. of the pure metal may be obtained. Large quantities of this ore occur in a quartz vein which, it is calculated, will certainly yield 200,000 puds of metallic nickel. Recent analyses by Huntington prove that the ore from the quartz vein contains about 7 per cent., and the soft ore 14–19 per cent. of nickelous oxide. It is proposed to prepare the pure metal electrolytically. Samples of the latter have given an excellent alloy with steel and aluminium. The alloy contains 60 per cent. of iron, 20 per cent. of nickel, and 20 per cent. of aluminium.—A. R.

Dry Concentration of Antimony Ore. J. Heard. Eng. and Min. Journ. 47, 187–188.

AFTER referring to the commercial impossibility of concentrating low grade stibnite ores by wet methods, the author describes the results of some experiments with one of Paddock's pneumatic jigs. (See Eng. and Min. Journ., 1886, July 3rd.) In crushing the ore it was found that the portion which passed through a 60-mesh screen required no further concentration, and attention was chiefly confined to the portion which passed a 24-mesh screen, but remained on the 60-mesh. This material contained 18.27 per cent. of Sb_2S_3 , and the result, after working at the rate of 120 pounds per hour, showed: heads, 78.34 per cent.; middlings, 16.54 per cent.; tailings, 7.5 per cent.; and the respective quantities were as 1:2:5. No clean particles of stibnite, free from gangue, could be discerned in the tailings, and only 3.81 per cent. out of the 7.5 per cent., was present as Sb_2S_3 , the remainder being there as oxide, which could not be expected to concentrate. Much, however, depends on the speed of the machine, the pitch, the feed, &c., the slightest variation in these producing marked differences in the results. The same material worked through at 1,908 pounds per hour, gave heads, 83 per cent. of Sb_2S_3 , and tailings, 10.73 per cent.

Coarser material did not work so well, the portion which passed a 12-mesh but remained on the 24-mesh sieve, and which contained 14.12 per cent. of stibnite, gave heads containing 74.53 per cent.; middlings, 18.26 per cent.; and tailings, 10 per cent.; rate of working 1,500 pounds per hour.

An experiment was made with a limestone of sp. gr. 2.77, containing 10 per cent. of garnet of sp. gr. 3.16; size between 24 and 60-mesh, and rate of working 930 pounds per hour. The heads contained 49.45 per cent. of garnet; the middlings, 8.65 per cent.; and the tailings, 2.75 per cent.

The best results were obtained with the ore which had passed a 24-mesh screen, and the best working conditions for this material were found to be:—machine running 540 strokes; 1,460 pounds per hour; stroke, $\frac{1}{2}$ inch; hopper in top-hole; pitch, 7°; dip, 2°. The experiments were abruptly suspended, but the results are considered satisfactory, although insufficient to show the cost of working.—A. W.

PATENTS.

Improvements relating to the Production of Metallic Compounds or Alloys. J. Sinclair and J. P. Smith, London. Eng. Pat. 2182, February 13, 1888. 6d.

The patentees claim the use of "hard spelter" in making copper, tin, and zinc alloys, and the use of potassium salts as fluxes in preparing the alloys.—H. S. P.

Improvements in the Method of making Aluminium Bronze. L. Q. Brin, Paris, France. Eng. Pat. 3547, March 7, 1888. 6d.

THE patentee heats a volatile salt of aluminium, such as the chloride, in a fire-clay retort, and conducts the resulting vapours into a muffle containing copper or some alloy of copper in the form of scrap, and which is set in a reverberatory or other suitable furnace heated to 800°–900° C. The copper is previously cleaned by pickling, and coated with a flux such as a mixture of two parts of borax, two of sodium chloride and one of sodium carbonate made into a paste with water. The aluminium salt is said to be decomposed and the nascent aluminium to combine with the copper, forming an aluminium bronze. Any waste vapours or gases pass into a cooled receiver of glazed earthenware, where any volatile salt of aluminium is condensed, and can be used over again.

With regard to working details, the retort may be charged with a mixture of 100 parts of clay (containing about 50 per cent. of alumina), 125 parts of sodium chloride or other suitable chloride, and 15 parts of fluorspar; an alternative charge consists of 100 parts of clay, 80 parts of sodium chloride, potassium chloride, &c., and 65 parts of powdered slag obtained as a residue in a previous operation. The vapours of the aluminium salt are carried over from the retort in which they are produced by a stream of inert or reducing gas such as is got by passing air through red-hot coke. A charge of 240 lb. in the retort suffices to convert 1,000 lb. of copper into 1½–2 per cent. aluminium bronze. By repeating the treatment the alloy may be enriched to any desired extent.—B. B.

Improved Apparatus for the Expulsion of Chlorine or other Noxious Gases from its Solution. W. D. Bohm, Acton. Eng. Pat. 4699, March 27, 1888. 8d.

THE gases are expelled by blowing air or steam through the liquid or semi-liquid mass containing them. The operation is to be carried on in a closed chamber, with an inlet pipe, dipping below the surface of the liquid in the chamber, and an exit pipe to take away the noxious gases. The method is specially adapted to the "Newberry-Vautin" chlorination process for extracting gold. (This Journal, 1887, 824.)—H. S. P.

Improvements in the Manufacture of Aluminium and Alloys of Aluminium. S. Pearson, J. Liddon, and J. H. Pratt, Birmingham. Eng. Pat. 5316, April 10, 1888. 6d.

ONE hundred parts by weight of cryolite are mixed with 50 parts of bauxite, kaolin, or aluminium hydrate, 50 parts of calcium chloride, oxide, or carbonate, and 50 parts of coke or anthracite, all being in powder. The resulting mass is heated to incipient fusion in a furnace or in a crucible made of, containing, or lined with carbon, in which case the carbon may be omitted from the mixture. The heating is continued for two hours, at the end of which time it is alleged that the aluminium is reduced and exists disseminated in minute globules throughout the mass. A mixture of 25 parts each of potassium and sodium chlorides is then added, and the temperature raised to bright redness; the aluminium collects at the bottom of the crucible. A better separation is, however, effected by powdering, washing and drying the melt, and adding it to fused zinc, which alloys with the aluminium and can afterwards be removed by distillation. If copper be used instead of zinc in this process aluminium bronze is obtained.

Other fluxes than those mentioned may be employed.

—B. B.

Improvements in the Production of Alkalis and Alkaline Salts from the Slag resulting from the Manufacture of Ingot Iron and Steel. T. Twynan, London. Eng. Pat. 5386, April 11, 1888, 6d.

THE phosphorus in phosphoric pig iron is removed by alumina in combination with some basic body such as lime or soda. The resulting slag consists largely of

aluminium phosphate mixed with silica, iron oxide, &c. This slag is ground and mixed with sodium chloride and coke-dust, moistened with water, made up into briquettes and dried. These are stacked in a enpola together with a little coke to serve as fuel. When the mass has attained a red heat, a current of superheated steam is introduced, and this together with the blast employed causes a reaction between the aluminium phosphate and sodium chloride, resulting in the production of sodium phosphate and sodium aluminate, hydrochloric acid being simultaneously given off. When the reaction is finished, the mass is withdrawn from the furnace, digested with water, and the dissolved phosphate and aluminate of soda separated by crystallisation. The sodium phosphate may be converted into calcium phosphate and sodium hydrate, whereas the sodium aluminate is decomposed by carbonic acid into sodium carbonate and alumina, which latter is re-used in the converter.—S. H.

Improvements in Treating Auriferous and Auvoargentiferous Ores. J. Weirich, Béziers, France. Eng. Pat. 6104, April 24, 1888. 6d.

A PROCESS for preparing for amalgamation auriferous minerals in which the gold is chiefly associated with antimony, arsenic, and sulphur, and from which the gold cannot be extracted by amalgamation after known methods of treatment. The ores are first roasted and then fused with sodium carbonate or calcium carbonate, or a mixture of these, with the addition of a small quantity of charcoal. Sometimes silica must be added to obtain fusion. The fused mass is ground to a powder, from which the gold and silver can be separated by amalgamation.—H. S. P.

A New and Improved Method of making Malleable Iron Castings. C. C. Townsend, Madras, E. Indies. Eng. Pat. 10,347, July 17, 1888. 4d.

WROUGHT iron scrap is melted down in crucibles with the addition of small quantities of phosphorus and silicon, and when cast gives a malleable material which is also capable of being chilled. The best mixture is:—22 lb. of scrap, 7 oz. of fine river sand, and 5 oz. of bone-ash, with a small quantity of glass as a flux.—A. W.

Improved Method of and Apparatus for Extracting Tin from Scraps containing it. L. A. Groth, London. From O. Leprévost-Bourgerel and E. Pierron, Paris, France. Eng. Pat. 13,234, September 13, 1888. 8d.

THE use of hydrochloric acid, dissolved in water or in the state of a moist gas, for the extraction of tin from tinned iron scraps, is unsatisfactory owing to the facility with which the iron is acted upon. The inventors employ dry gaseous hydrochloric acid, obtained by heating to 160° C. commercial hydrochloric acid with twice its volume of sulphuric acid of sp. gr. 60° B., or by drying with sulphuric acid of sp. gr. 60° B. the gas evolved by the action of sulphuric acid on a chloride. The scraps are placed in a series of closed chambers connected with each other by pipes for conveying the gas. The gas enters at the bottom of each chamber, passing out by a pipe at the top which is connected to the bottom of the next chamber in the series. The process is so arranged that the strongest gas comes first in contact with the scrap that has been most acted on.

When this scrap is sufficiently acted on the chamber containing it is disconnected from the rest, and the scale that has formed on the scrap is dissolved off with water. The tin is then separated from the solution of stannous chloride thus obtained by immersing in it zinc ingots covered with calico. The crystals of tin that are precipitated upon the calico are collected, pressed to remove adhering solution, and melted with zinc chloride, which protects the molten metal from oxidation, and can be used repeatedly.—H. S. P.

Improvements in and relating to the Utilisation of Waste Pickle from Tinning and Galvanising Works where Hydrochloric Acid is used in the Process of Pickling. H. J. Kirkman, Swansea. Eng. Pat. 14,061, September 29, 1888. 4d.

TO the waste pickle, milk of lime is added in sufficient quantity to neutralise the free acid and to precipitate the iron as hydrate. The oxide formed can be used for purifying illuminating gas, and for other purposes.—S. G. R.

Improvements in or relating to Protecting Surfaces of Iron or Steel from Oxidation and for giving them an Ornamental appearance, applicable for Gun Barrels and other bright work. J. Ewart, Birkdale. Eng. Pat. 16,451, November 13, 1888. 6d.

THE surface of the article is rendered perfectly smooth; it is then treated with nitric acid or other solvent until the grain of the metal appears, when it is washed, dried, heated to a dull red heat, avoiding oxidation, and immersed while hot into any, but preferably castor, oil till cold. The effect is a firmly adherent thin carbonaceous coating with a dull black appearance which can be made bright black by lacquering.—A. W.

Improvements in the Process of and Apparatus for Zincing Metal Articles. F. W. Koffler and A. Breden, Vienna, Austria. Eng. Pat. 16,674, November 16, 1888. 8d.

THIS is an improvement on Eng. Pat. 12,485 of 1885 (this Journal, 452) for zincing sheet metal by removing the surplus zinc from the sheet by revolving brushes whilst it is being withdrawn from the zinc-bath. The patentees now claim the process as applied to metal articles of various kinds besides sheet metal. Zincd articles treated in this way may at once be coated with another metal by mere immersion in a bath of the molten metal (a result which must otherwise be obtained by plating or electro-plating), the reason being that by brushing off the surplus zinc a clean alloy of the remaining zinc and the metal of the article is obtained, having a melting point high enough to bear immersion in the bath of metal with which the article has to be coated; but if the surplus zinc be not removed it burns when the article is dipped in the bath and the zinc oxide formed prevents further alloying. Drawings are given of the machinery used in the operation.—H. S. P.

Improvements relating to the Desulphurisation of Ores and to the Decomposition of Metallic Salts and similar Compounds. H. H. Lake, London.—From O. B. Peck, Chicago, U.S.A. Eng. Pat. 17,069, November 23, 1888. 8d.

THE object of this patent is to overcome, by centrifugal force, the chemical affinity of the various elements in compounds such as regulus, sulphides, pyrites, sulphates, mattes and speise. The molten material, such as copper regulus, is run into a kind of revolving bottle and there subjected to great centrifugal force, by which it is claimed that the metals come out of combination with the sulphur and arrange themselves in the order of their densities. It is also maintained that the sulphur, which in the ordinary smelting process is lost, can be recovered as such in a "greater or less state of purity."—A. W.

Improvements in Crucible Furnaces. C. A. Piat, Paris, France. Eng. Pat. 18,414, December 17, 1888. 8d.

THE furnace consists essentially of two crucibles, one above the other, whereby the waste gases from the fuel employed to melt the charge in the lower are made to heat a fresh charge in the upper crucible. The lower crucible revolves on trunnions, as in the ordinary Piat furnace, so that it may be emptied without removal from the furnace, and the upper crucible, with a removable base and a few holes

in its sides to permit circulation of the hot gases through the charge, is lowered down so as to form a lid to the former. Drawings are given.—A. W.

Improvements in and relating to a New and Useful Process for Treating Crude or Low Grade Steel to Produce a Refined or High Grade Steel. H. M. Redemann and R. J. Tilford, Louisville, U.S.A. Eng. Pat. 2068, February 3, 1889. 6d.

This process is for converting Bessemer and other mill steels with "coarse grain" into a more refined material with a "fine grain and silky fracture," and with an increase in carbon, "tensile strength, elasticity, toughness, and ductility." The metal is heated to a white heat and plunged into a bath capable of yielding a hydrocarbon gas. The bath consists of glycerin and water in the proportion of 3 ozs. of the former to half a gallon of the latter, and while this gives good results, still better ones are obtained if to the above bath are added in various proportions, spirits of nitre, ammonia, ammonium chloride, zinc sulphate and ammonium alum. Many advantages are set forth in the specification, and the superiority is maintained of this process over the cementation method.—A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Secondary Batteries. W. H. Preece. J. Soc. Arts 22, 510.

THE results of five years' experience of different forms of storage cells is summarised. One of the greatest difficulties with such cells has been found to be due to the formation of lead sulphate on the plates. The method first suggested by Barber-Starkey to avoid this evil has been tried. It consists in adding a solution of sodium sulphate to the dilute sulphuric acid with which the cells are usually charged. Comparative experiments have shown the immense benefit of the sodium sulphate. It completely prevents sulphating and at the same time does not impair the cells in any way. The electrolyte that gives the best results is made as follows:—To a quart of saturated carbonate of soda solution add slowly, during continuous agitation, 12 fluid ounces of strong sulphuric acid. This mixture constitutes the sulphate of soda solution. One part of it by volume is added to 19 parts of water and 5 parts of sulphuric acid. The electrolyte so made should have a specific gravity of 1.21.

—W. W. H. G.

PATENTS.

An Electrical Battery. N. G. Thompson, London. Eng. Pat. 3550, March 8, 1888. 6d.

CARBON, packed in with some such metal as copper, is employed as negative electrode, in a "chloridising" solution such as hydrochloric acid, common salt, &c. The metal employed must be electro-positive to carbon in the particular solution, and electro-negative to the zinc or other metal employed as positive electrode. The action with copper and carbon as negative electrode, is that the chloride of copper existing in suspension is decomposed, the copper being deposited and the chlorine uniting with the hydrogen adhering to the negative electrode. This deposited copper is, however, taken up by the unexpended portion of the "chloridising" solution, and the liquor thus regenerated. When crushed carbon is used with a weak "chloridising" liquor a "distributed conductor" may be used to lessen the resistance.—E. T.

Improvements in the Electrolytic Production of Metals. C. Hoepfner, Berlin, Germany. Eng. Pat. 4626, March 26, 1888. 6d.

This invention relates principally to copper, and depends on the fact that while hitherto copper has been reduced from ores and matte, and refined from the crude metal by the electrolysis of solutions which contain its salts in the cupric state, it is now proposed to use them in the cuprous condition, thereby economising the energy necessary. The process is carried out as follows: Chlorinated, roasted, waste ores are extracted with a strong solution of common salt, and the cupric chloride thus obtained reduced by any suitable means, such as sulphurous acid or ores containing metallic sulphides. Impurities, such as tin and arsenic, are precipitated by adding "sulphur compounds of the alkalis or oxides or carbonates of the alkalis, either in solid or liquid form;" and the precious metals are precipitated by iron or copper or by electrolysis. The purified solution of cuprous chloride is electrolysed with carbon electrodes, and yields 40 kilos. of copper per horse-power in 24 hours. At the anode, which is separated from the cathode by means of a parchment membrane, cupric chloride is produced, and is converted into cuprous chloride by the use of the reducing agents mentioned above, which may be used either within or without the decomposing vessel. If the ores to be treated contain gold, it is necessary to push the action at the anode further than is generally necessary, viz., until the liquid there contains free chlorine.

During the lixiviation of the ore, and afterwards during electrolysis, the solution is preferably agitated, and for this purpose gases containing no free oxygen should be used. Gases containing carbonic oxide are said to be best, because of the fact that the union of this constituent with the cuprous chloride aids the depolarisation of the electrodes.

Copper ores containing silver, or silver ores themselves, may be treated by the process, the silver being dissolved as chloride in the highly-chlorinated liquid at the anode, and precipitated from this solution by electrolytic or chemical means.

The same occurs with lead, using hot solutions, save that no special process for its precipitation is necessary, as it precipitates spontaneously on cooling.

The patentee claims the use of the other two halogens as well as that of chlorine.—B. B.

Improvements in Storage Batteries. H. Edmunds, London. Eng. Pat. 5191, April 7, 1888. 6d.

To prevent "spraying" in accumulator cells, paraffin wax, or any suitable insulator, is melted and poured upon the surface of the liquid in the cell, so that a solid cake may be formed over it. A hole is made, and covered by a cap, from which, if desired, the gases may be led away and utilised. If necessary, the cake may be strengthened by a suitable framework, or by ledges round the sides of the cell. The generation of gases during charging will cause liquid to rise through the hole and flood the top of the cake. If this is considered undesirable, some of the liquid may be siphoned out, so as to leave a space below the cake.—E. T.

Improvements in Galvanic Batteries. P. R. de Fauchaux D'Humy, London. Eng. Pat. 6322, April 28, 1888. 8d.

This invention is for facilitating the processes of emptying and filling a battery of many cells.

Each battery cell is divided into three compartments by two partitions of carbon, which themselves form the negative electrode. The middle compartment is meant to contain the depolarising liquor, and communicates at the bottom with an accessory cell at the side. The two outer compartments contain the positive electrode and the acid-working solution, and communicate in like manner with a second accessory cell on the other side. All the accessory cells of the different battery cells on one side communicate by separate flexible tubes with a trough that can be raised above the cells or lowered below them. When lowered the liquid from the cells flows through the accessory cells and

their flexible tubes to the trough, and the cells thus become emptied, or vice versa. The accessory cells on the other side, communicating with the other set of compartments, are connected in like manner with a second trough, that can be raised or lowered. At the top of the apparatus two supply tanks, containing the two liquors used, communicate, through flexible connexions controlled by screw pinch valves, with conduits, which, by short tubes ending above the different accessory cells, distribute to these fresh liquor when required. Each accessory cell is fitted with a lip, and any overflow passes by these lips into long troughs placed one on each side of the battery, and thence into general collecting vessels at the base of the apparatus.

The positive electrodes are attached to a shaft, and counterpoised, so that by moving a handle they can all simultaneously be removed from the cells. In the inventor's drawings there are two series of battery cells, one above the other, and similar moving parts in each are so connected as to move together by the movement of one handle.—E. T.

Improvements in Electric Batteries. B. Willeox, London. From B. A. Abakanowicz and A. d'Arsonval, Paris, France. Eng. Pat. 7876, May 29, 1888. 8d.

ELECTRODES exposing great surface, but with little internal resistance, are made by compressing small pieces of the material chosen in a tube or cylinder of porous material or perforated metal by a spring, weight or such device. In a typical device, the granules are covered by a plate, which is forced down by a spring, whose pressure is regulated by a nut screwing on a rod which passes down the axis of the cylinder, and is attached to its bottom.—E. T.

Improvements in Electric Batteries. A. Imshenetzky, St. Petersburg, Russia. Eng. Pat. 9381, June 27, 1888. 8d.

THE zinc in this cell is placed in a liquid that has a greater affinity for oxygen than zinc has, so that this liquid, and not the zinc, becomes the depolarising agent, and the zinc remains intact. The electrodes are zinc and carbon, and the exciting liquids (1) Solutions of sulphite or hyposulphite (thiosulphate) of sodium or potassium, these salts being converted during action into sulphates, which sulphates, by calcining with carbon and treatment with sulphurous acid, can be reconverted into hyposulphites, or into sulphites by conversion into carbouates and treatment with sulphurous acid, and (2) surrounding the carbon, a dilute chromic or manganic acid solution. The sulphate of potash formed after conversion into the carbonate and hydrate, can be calcined with manganese peroxide into potassium manganite. A solution of the latter salt on heating yields potassium manganate. Where facilities for utilising the by-products in this way do not exist, other well-known depolarisers may be used. The cell is divided into three compartments by two porous plates, the zinc occupying the centre one, and by an arrangement of tubes and cocks a continuous circulation of liquor is kept up.—E. T.

Improvements relating to Electric Secondary Batteries or Accumulators, and to the Manufacture of Electrodes therefor. L. Paget, New York, U.S.A. Eng. Pat. 17,223, November 27, 1888. 8d.

THE inventor casts a frame of lead with numerous thin vertical bars. These are completely imbedded in the pasted material, so that the whole plate has very little of its lead framework exposed. This is preferred for the negative plate. The positive is made of vertical strips of lead, corrugated obliquely, and so placed that the corrugations of adjacent strips cross each other. The strips are supported by a cross-bar at the top, but are free elsewhere. These plates, unlike the last, expose a very large amount of surface, can expand without buckling, and allow very free circulation of the liquid. They are "formed" in a fraction of the time required for Planté plates in "1 to 5 sulphuric acid" containing 10 per cent. of nitrite or acetate of ethyl, with a small amount of nitric or acetic acid (not more than 1 per cent. of nitric or 2 per cent. of acetic acid).

To get rid of sealing, the inventor constructs plates of numerous elongated stirrups or loops of transversely corrugated lead, the loops being packed with the paste, and attached above to a horizontal bar. These allow of free expansion. For portable accumulators, the containing case is made of conducting material, preferably lead or type-metal, and the alternate plates are soldered, burned, or otherwise metallically attached to it by their lugs at two or more places. The other set of plates are in the same way metallically connected by their top lugs with a lid or cover, insulated from the case. This arrangement has the additional advantage that if two or more cells be placed one upon the other, they are thereby at once connected in series.—E. T.

Improved Methods of Preparing Solution Compounds for Galvanic Batteries. W. P. Kookogey, Brooklyn, U.S.A. Eng. Pat. 320, January 8, 1889. 4d.

THE improvements are in the manufacture of dry battery compounds from bichromate of soda, sulphate of soda, and sulphuric acid, in a more homogeneous form. Taking these ingredients, in the proportions of 7 : 8 : 16, in the order enumerated, one method is to dissolve the soda salts in about half the quantity of warm acid, and when cold add the rest of the acid all at once. Another method is to make a supersaturated solution of the bichromate in water, add half the acid warm, and dissolve the sulphate of soda in the liquor, then add, all at once, the rest of the acid. In either case, after adding the second part of the acid, the liquid must be stirred as vigorously as possible till solidification takes place.—E. T.

Improvements in and relating to Electric Secondary Batteries or Accumulators. O. Lugo, New York, U.S.A. Eng. Pat. 746, January 15, 1889. 6d.

THIS accumulator is built on the principle of Grove's gas battery. Metallic zinc is suspended in a solution of chloride of lead in sodium chloride. Lead in a finely-divided or allotropic condition is thereby deposited on the zinc. A little copper sulphate is added, by which finely-divided copper is thrown down. The two metals, in their finely-divided state, occlude oxygen or hydrogen readily by a mere physical process, but resist oxidation or any change of form. Accumulators are made by packing this material into porous jars round metallic or metalloid plates.—E. T.

Improvements in the Manufacture of Electrodes for Secondary Batteries or Accumulators. L. Paget, New York, U.S.A. Eng. Pat. 2066, February 5, 1889. 6d.

TO produce a plate in which the active material merges into the supporting plate without any distinct line of demarcation, a two-part mould is taken, of the usual construction for casting plates, and the parts intended to form the lead-grid are packed with some substance which is able to reduce the active material when in a fused state. The fused active material being run into the mould, where it touches the reducing agent, it is reduced to lead, which acts as the supporting frame or grid, and must necessarily be in the most intimate possible contact with the active material. As reducing agents carbon or carbon and nitre are suitable for oxide of lead. For chloride of lead, powdered zinc, tin, or magnesium may be used.—E. T.

Improvements in Electric Contact and Alarm-Thermometers. M. Huhl, J. M. and F. Lautenschläger, Berlin, Germany. Eng. Pat. 2628, February 14, 1889. 6d.

THE object of this invention is to produce a thermometer that shall complete an electric circuit at any desired temperature with great accuracy. For this purpose, the capillary tube of the thermometer is contracted just below the lowest division of the scale. Immediately below this contraction a platinum contact wire is sealed in, while a second is sealed into the bulb. To set the thermometer to complete the circuit at a temperature of say 50°: it is first heated accurately to the point marked 50° on the scale and

then allowed to cool. In cooling the mercury column breaks at the constriction, and the mercury below the latter sinks past the platinum contact into the bulb. If, however, the temperature should rise to 50°, the mercury in the bulb expands till its end just touches the platinum wire at the constriction and so complete the circuit. To use the thermometer for a higher temperature the thermometer is merely heated to that temperature as before, but for a lower temperature the column of mercury must be joined by shaking before using.—E. T.

Improvements in Galvanic Batteries. E. D. Cross, Chicago, U.S.A. Eng. Pat. 2949. Feb. 19, 1889. 8d.

In the outer containing cell is placed a porous pot, and inside that a second. The cell is thus divided into three compartments. In the first, or outermost, carbon tubes are hung in a circle from a carbon ring which acts as a lid to this cell. In the second compartment are placed zinc rods suspended by screws from a ring of good conducting material which acts as a lid to this second cell. The electrodes of the third cell are of carbon, and form a repetition, on a smaller scale, of those of the first. The carbon tubes have a C cross-section. They are lined first with a layer of porous material, preferably paper, and then filled up with asbestos wool. The lids of compartments one and three are coated above and below with paraffin wax, which helps to steady the carbon tubes. A tube, of suitable material, passes from the top of the outer compartment to the bottom of the inner, which is packed with alternate layers of carbon and asbestos and then filled with water. The fumes from the outer compartment are thus absorbed by the liquor of the inner; this liquor acquiring thus strong oxidising properties, is able to supplement the outermost compartment, which contains nitric acid with a small proportion of ammonium nitrate. The porous pots may be painted with a gelatin solution to prevent too rapid diffusion.—E. T.

PATENT.

Improvements in that Class of Detergent Compounds in which Ammonia is employed as one of the Ingredients. W. P. Thompson, Liverpool. From C. C. Parsons, Brooklyn, U.S.A. Eng. Pat. 7095, May 12, 1888. 6d.

Two ingredients which when together in contact with water, will evolve ammonia, are dried, granulated, and mixed, and there is then interposed between their particles a protecting medium, the object of which is to prevent contact between the substances, and thus postpone the evolution of ammonia until the desired moment. Such protecting media are heavy-bodied paraffin oil, resinous oil or varnish, glue, size, or paraffin wax. The compound produced by incorporating the granular salts (e.g., 66 parts of sulphate of ammonia and 60 parts of soda-ash) with the liquid medium may be used alone, or mixed with soap or soap-powder, and with insoluble detergents, such as sand, pumice, &c.—W. L. C.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

PATENTS.

Improvements in Preventative and Anti-Fouling Coatings for Ships' Bottoms. J. B. Hannay, Cove Castle. Eng. Pat. 7033, May 11, 1888. 4d.

This is an improvement on Eng. Pat. 12,499 of 1886 (this Journal, 1887, 601), in which patent a preservative coating was formed "by combining linseed oil, rosin, mineral naphtha, powdered metallic zinc, oxide of zinc, or magnesia, or oxide of iron, or other basic oxide or mixture of basic oxides, and red oxide of mercury." In the present invention mercurous chloride (calomel) is substituted for the oxide of mercury, as much calomel being used as of red oxide formerly. "The combining of mercurous chloride with any of the coating compositions in use renders them more satisfactorily anti-fouling."—B. II.

Improvements in the Treatment of Tar Oils for Use as Wood-Preserving Paints or Coatings. R. Avenarius, Ganalgesheim-on-the-Rhine, Germany. Eng. Pat. 7398, May 18, 1888. 6d.

This invention relates to the treatment of tar oils for use as a preservative paint ("carbolineum") for wood, and consists in subjecting the tar oil to the action of chlorine. By the action of the chlorine "the antiseptic property of the 'carbolineum' is greatly increased," and "the unpleasant smell replaced by an agreeable one." "The specific gravity, viscosity, and drying quality are increased, and a varnish-like lustre is imparted to the paint."—B. II.

Improvements in or relating to Bronze or other Metallic Paints. Lizzie H. Goggs and T. T. Irvine, Liverpool. Eng. Pat. 7708, May 26, 1888. 4d.

BRONZING has hitherto been performed by mixing bronze powder with a sticky material such as gum water, but in this invention an enamel that will fulfil the desired conditions is composed as follows:—Enamel varnish, half a gallon; terebene, one quart; turpentine, one quart. To this mixture is added a fourth of its weight of the bronze or metallic powder.—B. II.

An Improved Composition for Preventing the Fouling of Ships' Bottoms and other Submerged Structures. W. O. Wotton, Southampton. Eng. Pat. 11,554, August 10, 1888. 6d.

For the purposes of this invention the vehicle and the ingredients conferring the anti-fouling properties are kept separate till required for use. The vehicle consists of caoutchouc dissolved in turpentine or other suitable solvent, boiled linseed oil, and common rosin.

The anti-fouling ingredient is powdered metallic copper or alloy of copper, but preferably pure precipitated copper. With this metallic powder is mixed a suitable proportion of red lead. These powders are mixed dry, and when required for use a suitable proportion of the mixed powder is thoroughly incorporated with the vehicle or menstruum. The composition is applied with a brush over a priming coat composed of the vehicle with the addition of red lead to give it body.—B. II.

An Improved Process for Painting on Glass, Porcelain, Tin, and the Like. W. Michaelson, London. Eng. Pat. 338, January 8, 1889. 4d.

THE design is first drawn with etching ink on the article taken, and then after cleaning with turpentine, ordinary oil tube colours are laid on and allowed to dry. It is then brushed over well with turpentine and another coat applied either once or as often as may be required. The details of the drawing are now made out with transparent oil tube colours, and the whole varnished with white copal varnish.

—S. G. R.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENT.

Improved Apparatus for Tanning Hides and Skins by the Aid of Electricity. L. A. Groth, London. Eng. Pat. 742, January 17, 1888. 8d.

INSTEAD of placing the hides, &c. in a revolving drum, the patentee employs an open tank containing the tanning solution. In this tank and more or less immersed in the liquor is placed a rotating drum or cage composed of bars secured to suitable framework. The hides are placed in the cage, which can be arranged to rotate either horizontally or vertically. When arranged to rotate horizontally the interior of the drum is preferably provided with pegs projecting radially inward, to keep the hides from the internal surface of the cage and to prevent the hides from rolling into a ball shape. When arranged to rotate vertically the hides are suspended on the bars provided. Suitable electrodes are provided in the tank or in or on the cage. Drawings are given, and the inventor states that the hides or skins are tanned in four days.—B. II.

XV.—AGRICULTURE, MANURES, Etc.

Chili Saltpetre as a Manure for Wheat. A. Wolff. Brauns. landw. Zeit. 1888, 3.

From the results obtained in some experiments (no analysis of soil given) it was observed that phosphatic manures were required, but the yield with them was greatly increased when Chili saltpetre was also used. The phosphate, as ammonium superphosphate, was applied in autumn, the saltpetre in spring, but there were no comparative experiments.—D. A. L.

Origin and Properties of Humus. F. Hoppe-Seyler. Zeits. f. phys. Chem. 13, 66—121. (Compare C. G. Eggertz, this Journal, 1889, 293—294.)

IN support of the view that the humus arising from the decay of dead vegetation originates from the tannins and carbohydrates stored in the living plant, the formation and properties of humic substances from various sources are discussed. Cellulose yields humic substances by the action of acids, by heating with water at 180°—200° and by fusion with potash in presence of oxygen; in a sealed tube with water formic acid, catechol, and protocatechuic acid are also formed, the last two only when alkali is liberated by the action of the water on the glass. Many other carbohydrates, such as sugars, also yield humic substances by the action of acids and by caustic alkalis in presence of oxygen. Neither white beech gum nor cellulose yield humic substances by marshy fermentation. By the action of strong potash at 240° on cellulose in the absence of oxygen, oxalic, protocatechuic, formic, acetic, and other volatile acids are obtained with the evolution principally of hydrogen with a little marsh gas, but no humic substances are formed. All the humic substances obtained as above, yield when fused with potash at 250° *hymatomelanic acid*, protocatechuic, fatty, and oxalic acids, and catechol. *Hymatomelanic acid* is the provisional name given by the author to a brown amorphous acid which is soluble in alcohol, insoluble in ether, and swells in water.

Phlobaphene obtained from oak yielded protocatechuic, formic, acetic, oxalic, and hymatomelanic acids, also a fusible reddish-yellow crystalline acid soluble in ether. *Hymatomelanic acid* is also obtained from the brown substances produced by the action of ammonia and oxygen on pyrogallol and protocatechuic acid, and from the humic substances derived from dead plants, furfuraldehyde, peat, and lignite, but not from azulonic acid prepared from hydrocyanic acid.

The author classifies humus substances and phlobaphenes into three groups. Those of group I. are insoluble in both alcohol and potash, but combine with alkalis to form the slimy masses which are difficult to wash and obstinately retain alkali; by fusion with potash they are converted into substances belonging to the other groups. According to Mulder the humins and ulmins fall in this group. Group II. includes those substances which are soluble in alkalis even when very dilute, and are reprecipitated by acids. Phlobaphenes, humic and ulmic acids yield members of this group. In group III. are classed those members of group II. which after reprecipitation are dissolved completely and readily in alcohol. They form a wrinkled skin on the surface when the alcohol is evaporated, and when cool set to a fissured gelatinous mass which melts when warmed on a water-bath; after drying they are incompletely or not at all soluble in alcohol. To this class belong phlobaphenes, portions of humic and ulmic acids, and hymatomelanic acid.

The author obtained pure cellulose, pure gum, and lignin from fragments of an oak post which had been under water for centuries. Lignin may be regarded as an ether, probably of cellulose and lignic acid; it is remarkably stable, but is capable of quantitative resolution. Lignic acid liberated in this manner assists largely in the formation of humic acid in humus, peat, and lignite.—D. A. L.

Detection of Nitrates in Soils. Frank. Landw. Jahr. 17, 723—724.

See under XXIII., page 420.

Significance of Potassium in Plants. R. Lüpke. Landw. Jahrb. 17, 887—913.

PLANTS of *Phaseolus multiflorus* and *vulgaris* were grown in nutritive solutions with and without potash, and to minimise the supply of potash emanating from the seed, portions of the cotyledons were removed as early as possible.

The plants cultivated in the nutritive solutions without potash vegetated far better than in pure water, even producing starch in the assimilation organs, metamorphoses of material, &c., but they were nevertheless much behind the plants grown under normal conditions, inasmuch as the growth and production of organs was restricted.

The results indicate that potash does not stimulate some special function, but like nitrogen, phosphorus, sulphur, &c., is generally useful in the plant, probably taking part in the building up of every cell. The precise rôle played by potash is, however, still uncertain.—D. A. L.

Assimilability of the Phosphoric Acid in Basic Slag. Bull. d. l. stat. agronom. d. l'Etat à Gembloux, 1888, 1—23.

WHEAT and oats were grown on two soils of the following composition with various manures, including superphosphate and basic slag, containing 2.62 per cent. of citrate-soluble phosphoric acid, and 19.26 per cent. of phosphoric acid soluble in hydrochloric acid:—

	H ₂ O ₂	Org. Mat.	Fe ₂ O ₃ , Al ₂ O ₃	CaO	MgO	Na ₂ O	K ₂ O	P ₂ O ₅	SO ₃
Soil 1. Clay-sand.....	20.22	26.12	17.74	2.37	1.69	0.23	0.76	0.65	0.26
Soil 2. Sand.....	9.80	6.00	4.48	1.55	6.25	0.11	0.15	0.10	0.01

—	CO ₂	SiO ₂	Insol. cold conc. HCl.	Org. Nitrogen.	Ammon. N.	Nitrate N.	Total N. per 1,000.	
Soil 1. Clay-sand,.....	0.56	0.30	929.10	Per 1,000	0.204	0.069	0.026	0.299
Soil 2. Sand,.....	..	0.11	977.14	Per 1,000	0.16	0.16

The crops on both soils were much benefited by the phosphatic manures, the slag acting quite as well as the superphosphate; the effect on the poorer sand soil, No. 2, was more marked than on the clay-sand, No. 1. Anyway, finely pulverised basic slag proved an excellent manure, and although its lime was without action, the large percentage of ferrous and ferric oxide in it did not interfere either with the growth of the wheat or with the production of sugar in beet, or starch in potatoes.—D. A. L.

Relation between Inorganic Nitrogenous Salts and Plants.

H. Molisch. *Naturw. Runds.* 3, 256.

The author has investigated Berthelot and André's view that nitric acid can be produced in plants from other nitrogenous compounds. Cultivations in nutritive solutions containing ammonia, but free from nitrates, have led him to conclude that when a plant contains nitric acid, it must have obtained it from the soil, and if a plant contains more nitric acid than the subsoil, it is attributed to storage in the plant. The author has not found nitrites in plants, and these salts are not taken up by the plant from the soil, inasmuch as, if present, they are directly destroyed in the roots. Even when nitrites are presented to the plants in such a way that their oxidation is prevented before they pass into the plants, not a trace of nitrite is to be detected either in the surface, roots or other organs of the plant. Nitrates are likewise absent, therefore the disappearance of nitrites is evidently not due to oxidation, in fact, observations support the view that nitrites become reduced.

—D. A. L.

Preserving Green Fodder with Carbon Bisulphide.

A. Grete. *Chem. Zeit. Rep.* 13, 97.

See under XVIII., A., page 409.

On the Present Position of the Question of the sources of Nitrogen of Vegetation. Sir J. B. Lawes and J. H. Gilbert. *Phil. Trans. Royal Soc., Lond.* 1889, 1—107.

In addition to the experiments, an account of which the authors have already published (*J. Chem. Soc.* 1885), they now give further details of a similar series of experiments. Fallow-wheat was grown for eight years, without any addition of nitrogen, on land which for 30 years previously had received no artificial addition of nitrogen, in conjunction with three leguminous crops—*Trifolium repens*, *Melilotus leucantha*, and *Medicago sativa*. The total amount of nitrogen taken off with the leguminosæ was found, as in the former experiments, to exceed very considerably that removed in the wheat crop. The amounts of nitric nitrogen in these soils at the conclusion of the experiment was, in the case of the *Trifolium repens*, and the *Melilotus leucantha*, also very considerably greater than that in the wheat plots, the samples being taken to a depth of nine feet. In the case of the *Medicago sativa* plots, the amount of nitric nitrogen was less, which was however not altogether surprising since it is such a strong and deep-rooting plant, removing as it did eight times the amount of nitrogen that the wheat crops removed. That these crops feed to a large extent on nitric nitrogen is shown by the fact that in the case of the *Trifolium repens* plot there was much more nitric nitrogen in 1883, when the crop failed, than in 1885, after 100 lb. nitrogen had been removed in the crop. Further, the percentage of total nitrogen in the surface soils of all the plots was less in 1881 than in 1885, at the conclusion of the experiments. An experiment similar to the foregoing was made by growing barley and red clover on bean-exhausted land, in which case, again the amount of nitrogen in the soils at the conclusion of the

experiment was greater than at the commencement, besides which a large quantity of nitrogen had been removed in the crops.

Experiments were also made on the nitrification of the nitrogen of the soils, and it was found that the nitrogen is susceptible of nitrification, and that the nitrification is more active in leguminous than in graminaceous crop subsoils. At the same time the experiments did not indicate that the necessary conditions were adequately available to explain the very large accumulation of nitrogen which were made by, for instance, the lucerne and the red clover, and experiments were therefore made to see if possibly nitrogenous organic matter is dissolved by the juice of the plant root, which is acid, and thus more directly assimilated. The result of such a series of experiments, in which the solvent action of dilute formic, acetic, oxalic, malic, citric, and tartaric acids was estimated, showed that nitrogenous organic matter is soluble in such solutions, but that the solvent action is limited. Such a series of experiments are, however, not altogether comparable with the action, if it actually take place, of the acid plant juice in the field.

—J. W. L.

XVI.—SUGAR, STARCH, GUM, Etc.

On the Sugar found in Different Kinds of Mushrooms.

E. Bourguelot. *Compt. Rend.* 108, 568—570.

The author has examined eight different kinds of mushrooms, belonging to the genus *Lactarius* and *Boletus aurantiacus*. They are first dried in the air, then at 50°—60° in a stove. After extracting with 80 per cent. alcohol, the latter is evaporated and the residue placed in an exsiccator. The crystals that separate after a few days are recrystallised several times from alcohol, and appear to be mannite. The quantity of this sugar found in the various specimens varies from 2.14—15 per cent. One of the above species of mushroom was extracted with boiling water shortly after it had been gathered. The filtrates were evaporated, the residue mixed with 80 per cent. alcohol, and otherwise treated as above. The product was found to be trehalose. The author concludes, that when gathered this mushroom contains trehalose, but by drying, the latter undergoes a change, which may be put down to maturing, since, like fruit, mushrooms continue to live for some time after they are gathered.—A. R.

American Vacuum Apparatus. Lippmann. Oesterr.

Zeits. f. Zuckerind. 1889, 760.

The construction and general arrangement of some sugar boiling apparatus employed in America are described. A vacuum pan of this sort is constructed of cast-iron rings which consist of separate segments, and there are four superimposed heating coils with 91½ square metres of heating surface. It yielded within four hours, at a temperature of 51.1° C. and 28½ in. pressure, 77,000 kilos. of syrup. A similar but larger apparatus made up of 12 cast-iron rings, and which was 14 metres high and 5½ metres diameter, yielded 175,000 kilos. of syrup in 2½ to 3 hours. The heating system consists of 72 coils, the condenser being 2½ metres diameter and 9 metres high. The cheap, safe, quiet, and regular working of this apparatus, and its durability, are much praised.—A. W.

Preparation and Use of Pure Grape Sugar. Seyberlich.
Zeits. f. Zuckerind. 39, 84.

STARCH is best saccharified by boiling with dilute nitric acid in vats, and, after neutralising, filtering, and evaporating the syrup to 36° B., crystallised at 20° C. The residue is submitted to hydraulic pressure in cloths, when a yellowish crystalline mass remains containing 88 per cent. of sugar, 10 per cent. of water, and 2 per cent. of impurities. The redissolved sugar previously treated with 10 per cent. of animal charcoal is refined in the same manner, and crystals may be obtained either anhydrous or with their water of crystallisation. 100 parts of starch give 90—95 of anhydrous sugar. Raw maize, rice, or sago may be similarly treated. Nitric acid is readily removed with sulphurous acid. The method is cheap and gives a very pure product. —A. R.

Quercite. H. Kiliani and C. Scheibler. Ber. 22, 517—520.

QUERCITE is a pentahydric alcohol according to Homann (Ann. 190, 282) and Prunier (Ann. Chim. Phys. V. 15, 1). Kannonikow found that on reduction it was chiefly converted into aromatic compounds, and assigned to it the constitution—

If Kannonikow's formula be correct, quercite is closely related to inositol, and on oxidation should yield similar products to those obtained from the latter by Maquenne (Ann. Chim. Phys. VI. 12, 1).

When quercite is treated with nitric acid of sp. gr. 1.39, first for 12 hours at 20°, and then for 36—48 hours at 30°, it yields mucic acid and trihydroxyglutaric acid, but no aromatic compounds could be obtained either by oxidation or any other chemical process. Only very small quantities of the two acids are formed, most of the quercite being converted into unstable compounds similar in behaviour to those obtained from sorbinose and levulose.

These results seem to show that quercite has not the constitution given to it by Kannonikow.—F. S. K.

Oxidation of Galactose-carboxylic Acid. H. Kiliani
Ber. 22, 521—524.

GALACTOSE-CARBOXYLIC acid is best prepared in large quantities as follows:—The crude product obtained by treating galactose with hydrocyanic acid (Ber. 21, 915) is decomposed with lime, the ammonia driven off, and the calcium precipitated in the cold with oxalic acid. The filtrate is boiled for a long time with lead carbonate, filtered, evaporated to a small volume, and then agitated with a small quantity of the pure lead salt. The latter is obtained by boiling a small quantity of the pure acid, prepared as already described (*loc. cit.*) with lead carbonate and recrystallising. After 1 to 2 days the crystals are separated, pressed, and purified by recrystallising from boiling water with addition of animal charcoal. The pure salt is dissolved in 5 times its weight of water, decomposed with sulphuretted hydrogen, and the pure acid obtained by evaporating over sulphuric acid. If the solution be evaporated at 100° the acid is partially converted into the lactone.

Carboxygalactonic acid, $\text{C}_7\text{H}_{12}\text{O}_9$, is formed when galactose-carboxylic acid is warmed at 50° for about 24 hours with $\frac{1}{2}$ times its weight of nitric acid of sp. gr. 1.2. The nitric acid is driven off by evaporating at 100°, the residue freed from oxalic acid by adding the necessary quantity of chalk, and, after neutralising with potash, evaporated to a syrup and mixed with excess of acetic acid. The hydrogen potassium salt, $2\text{C}_7\text{H}_{11}\text{O}_9\text{K} + 3\text{H}_2\text{O}$, separates after 12 to 24 hours, on rubbing, and is readily purified by recrystallising.

The crystalline cadmium salt, $\text{C}_7\text{H}_{10}\text{O}_9\text{Cd} + 2\text{H}_2\text{O}$, can be obtained by neutralising a solution of the pure acid potassium salt with potash, and, after concentrating, precipitating with cadmium nitrate.

The free acid, prepared by decomposing the cadmium salt with sulphuretted hydrogen and evaporating in a partial vacuum, crystallises in microscopic prisms and is sparingly soluble in cold water, but much more readily than mucic acid. It frits together at 168°, melts at 171° with evolution of gas, and does not reduce alkaline copper solutions.

The neutral potassium and sodium salts could not be obtained in a crystalline condition. The barium salt crystallises with three molecules of water.—F. S. K.

Seminose. R. Reiss. Ber. 22, 609—613.

It is well known that in many seeds the cell walls of the endosperm or the cotyledons are considerably thickened. In the case of some seeds it has been shown that this extra material serves as reserve food for the embryo, whilst in other instances this proof has not been forthcoming. The thickened cell walls consist either of amyloid or cellulose. The author has examined a number of those seeds which contain cellulose as reserve material. This cellulose differs considerably from ordinary cellulose. On hydrolysis with sulphuric acid, a dextro-rotary sugar is obtained. It reduces Fehling's solution and is capable of fermentation. The author gives to it the name of *Seminose*. It has not yet been obtained in the pure state, so that its properties are not accurately known, but it yields several readily crystallisable derivatives. Phenylhydrazine acetate mixed with an aqueous solution of seminose in the cold gives a very considerable precipitation of a colourless hydrazone. It is soluble in 80—100 parts of boiling alcohol of 50—60 per cent., but the greater part separates out again on cooling. It crystallises in small rhombic plates, melting at 185°—186° C. It is composed of one molecule of $\text{C}_6\text{H}_{12}\text{O}_6$ united to one of phenylhydrazine with separation of one molecule of water. Its formula is $\text{C}_{13}\text{H}_{18}\text{N}_2\text{O}_6$. A neutral aqueous solution of seminose gives with basic acetate of lead a white gelatinous precipitate, soluble in excess of the reagent. Its composition is $\text{PbO}(\text{C}_6\text{H}_{12}\text{O}_6) + \text{H}_2\text{O}$. Seminose readily yields an isonitroso-derivative in colourless crystals of the following formula, $\text{C}_6\text{H}_{13}\text{O}_6\text{N}$. It is fairly soluble in water, and melts at 176° C. with blackening. These facts conclusively prove that seminose is a distinct sugar. The formation of seminose is easily detected by the insolubility of its phenylhydrazone, which is a ready means of distinguishing the reserve food cellulose from ordinary cellulose and amyloid. Seminose was obtained from the following families of plants:—Palmaeae, Liliaceae, Iridaceae, Loganiaceae, and Rubiaceae. Seeds containing amyloid as reserve food do not give seminose on hydrolysis.—H. T. P.

A Sugar from Laminaria. R. W. Bauer. Ber. 22, 618.

A QUANTITY of laminaria taken from the sea about the end of August 1885 at Heligoland, was first extracted with alcohol and then heated with sulphuric acid on the water-bath. The solution was then neutralised with chalk, evaporated and extracted with alcohol. The author thus obtained a syrup, which solidified to a mass of crystals when a crystal of dextrose from lichenin was introduced. The substance had a sweet taste. Its specific rotary power was determined, with the following result:— $(\alpha)_D = +46.71^\circ$ at 14° C., concentration 1 grm. per 15 cc. of solution. The phenylhydrazone was also prepared; its melting point was about 140° C. On these grounds the author is of opinion that the formation of dextrose from laminaria has been proved.—H. T. P.

PATENTS.

An Improvement in Saccharometers. A. Horn, London.
Eng. Pat. 7411, May 19, 1888. 8d.

THIS invention consists in fixing a scale indicating percentages of sugar, alongside the Beaumé scale, on the hydrometers usually employed for ascertaining the density of saccharine solutions, so as to avoid the trouble of referring to tables.—W. M.

Improvements in and Relating to Centrifugal Machines for Use in the Manufacture of Sugar. G. F. Redfern, London. From W. P. Abell, Essequibo, British Guiana. Eng. Pat. 8052, June 1, 1888. *Sd.*

This invention relates to mechanism whereby the sugar discharged through the bottoms of centrifugals is conveyed to an ordinary elevator, or elsewhere as desired, without manual labour. The principal feature is the employment of a "conveyor in the form of a spiral or helical bar or rod, which is connected at two or more points with the driving shaft, but which throughout the greater part of its length is unattached to the shaft, and is at sufficient distance therefrom to permit the passage of the sugar between it and the shaft." This spiral works in a trough placed under the centrifugals, and it is claimed that the spiral does not triturate or damage the sugar in the same degree as screw blades or endless bands. Descriptions are also given of various arrangements for preventing the molasses from getting into the troughs along with the sugar and for discharging the sugar at will, either into the conveyor or out of the trough, but the specification and accompanying drawings must be consulted for the detailed manner in which these arrangements are carried out.—W. M.

Improvements in Evaporating Pans. G. Fletcher, Litchurch. From G. Brocklehurst, Barbadoes. Eng. Pat. 8053, June 1, 1888. *Sd.*

This is an improvement in open evaporating pans, and consists principally in constructing a hollow drum at the bottom of the pan, in which are a number of heating tubes and a large central tube through which the liquid circulates; the steam surrounds these tubes and a large heating surface is thus obtained. Drawings accompany the specification.

—W. M.

Apparatus for Cleansing Filtering Media. H. J. Allison, London. From the Casamajor Filter Company, New York, U.S.A. Eng. Pat. 18,860, December 27, 1888. *Sd.*

The invention described in this specification embraces a method and suitable apparatus for thoroughly cleansing the sawdust or finely-divided woody fibre used as filtering media for the removal of organic and suspended impurities from a solution of impure sugar. The sawdust containing the impurities is thoroughly agitated in a mixing vessel with a large volume of water; the vessel is of the usual type employed for such purposes. From thence it is transferred into a second agitating vessel where it is operated upon whilst suspended in water, by means of a current of air or steam distributed through the mass. When by these operations the dirt and foreign substances are removed and held in suspension in the water, the sawdust is separated from the contaminated water in an octagonal rotating sieve suspended horizontally; here it is subjected to a washing by clean water, and subsequently passed through two other similar apparatus, in each of which it is further purified by washing. Finally the cleansed sawdust is dried on a filter illustrated in the specification, resembling the ordinary form of vacuum filter.

The patentee claims the process as described, and the combination of the various steps and portions of the apparatus.—C. C. H.

XVII.—BREWING, WINES, SPIRITS, Etc.

Artificial Diastase. A. Reyher. Ber. 22, 414-419.

By the action of dilute acids on the gluten of wheat, at a temperature of 30°-40° C., for several hours, a considerable portion of the gluten is dissolved to an opalescent liquid. This solution is not coagulated on boiling. A few drops of a weak solution of potassium hydrate give a precipitate, soluble in a slight excess of potash. A few volumes of alcohol clear the solution, whilst a large quantity of alcohol

generally renders it turbid. Potassium ferrocyanide gives a precipitate soluble in much acetic acid. Mercuric chloride seems to have no effect. Guaiac tincture and hydrogen peroxide give an intense blue colouration. This reaction was not obtained when the gluten solution was boiled, or rendered too acid. According to Lintner this behaviour is characteristic of diastase. The solutions possess considerable diastatic activity, which is destroyed by boiling, and also destroyed, or at least retarded, by excess of acid or alkali. In one instance, the gluten of 20 grms. of wheat flour was digested for several hours with 100 cc. of a solution containing 1 gm. of potassium monophosphate in 500 cc. After solution had been effected 2 cc. of the artificial diastase were added to 2 grms. of starch gelatinised with 250 cc. of water, and the mixture digested for five hours at 40°-50° C. At the end of this time the solution was capable of reducing 135 cc. of alkaline copper solution. The author was unable to obtain an active ferment from other nitrogenous bodies, such as albumen and gelatin. Lintner's diastase reaction can be obtained from the soluble albuminoids contained in wheat flour. A slight proportion of acid increases the diastatic activity. The soluble nitrogenous constituents of ungerminated barley also possess diastatic activity, which is increased by a small quantity of acid. In two tables the author gives the results obtained on estimating the reducing power of a number of mashes made with barley, maize and malt, separate and also mixed, as well as mixtures of these with starch. The mashing liquor was in some cases water, in others a solution of acetic or metaphosphoric acid, containing 1 gm. per litre of the acid.—H. T. P.

Examination of Malt Extract. E. Dieterich. Hefen-berger Ann. 1888.

See under XXIII., page 424.

PATENTS.

Improvements in the Treatment of Brewers' or Distillers' Worts. W. Hucks, London. Eng. Pat. 6026, April 23, 1888. *Sd.*

This invention has for its object the removal of insoluble matters from wort after it has left the mash-tun. The apparatus consists of a continuous travelling band of some porous material, constructed somewhat like a paper machine. The wort flows over the gauze, through which it soaks, leaving the insoluble matter behind. The thick residue on the travelling gauze is removed by means of scrapers or brushes, after which it can be washed with clean water. If necessary, the wort is further treated in a centrifugal machine, which consists of a disc, on which are fixed a number of tubes radiating from the centre. The ends of these tubes can be closed during the rotation of the disc at the ends nearest the circumference. The wort flows continuously into these tubes about half-way between the centre and the circumference of the wheel. During its passage to the centre of the wheel the particles are precipitated to the ends of the tubes and retained till the ends are removed.—H. T. P.

Improvements in the Manufacture of Effervescent Wines and Beverages, and in Apparatus therefor. W. Gerbel, Korschach, Switzerland. Eng. Pat. 2785, February 16, 1889. *Sd.*

The inventor employs grape stalks as ferment bearers. For this purpose the bunches, after the grapes have been removed, are washed with water at 30° C. and partially dried. They are then sprinkled with sweet wine or other similar liquid and allowed to ferment. In order to completely ferment a liquid containing 4-5 per cent. of sugar, about 2 per cent. of the weight of the liquid of stalks are required. The advantage resulting from the employment of these stalks is that they constitute a filtering medium and attract the yeast formed.

In the manufacture of effervescent wines an apparatus is employed consisting of a wooden cylindrical vessel of about

220 gallons capacity. It is surrounded by a metal jacket capable of resisting eight atmospheres pressure, and is closed by a tight-fitting lid which closes both vessels. In the interior of the inner vessel is a cylinder to hold the grape stalks. This inner cylinder is the fermenting vessel, and it communicates with three other vessels of similar construction but only half the size, one of which is a sort of feed chamber for the fermenting vessel, while the other two act as recipients for the fermented wine. These are connected in their turn to a bottling apparatus. When the fermenting vessel is filled with wine and provided with ferment carrier, the lid is fastened down and the space between the inner and outer vessels filled with water. After about 8—10 days the wine is ready for transfer to the other two vessels mentioned above. All these apparatus are connected in such a manner that the same pressure exists in every part, so that the liquids can be transferred from one to the other without violent disturbance. The invention is employed with great advantage in the manufacture of champagne and other sparkling beverages. Wines may be bottled with the addition of grape stalk ferment and sugar without becoming turbid. The principal advantages are:—

- (a.) A rapid and uniform fermentation is produced in about six weeks.
- (b.) Deterioration of the wine is avoided owing to the rapidity with which fermentation takes place.
- (c.) The operation of bottling can be performed at all seasons of the year.—H. T. P.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

Oleomargarin Manufacture. Eng. and Min. Jour. 47, 210-212.

THIS description is taken from the Report of the Commissioner of Internal Revenue of America. The ingredients used are: Oleo oil, neutral lard, some liquid vegetable oil, as cotton-seed, sesame or peanut, butter, in the higher grades, cream and milk, together with salt, and annatto or other colouring matter.

The manufacturer of oleomargarin usually buys the refined materials in the open market. The manufacture of oleo oil is generally carried on in connexion with the large slaughter and packing houses situated in or near the principal cities. The caul and suet fats are removed from the freshly slaughtered heeves and placed in tanks filled with water at 75° to 85° F., where they remain from two to three hours before being transferred to other tanks containing iced water. By this procedure the fats are gradually deprived of their animal heat, and the danger of their becoming rancid is avoided, as would happen if the mass of fat were suddenly chilled by being placed directly in iced water. The caul, long or slaughter fat, is kept separate from the suet fat, which yields an inferior grade of oil.

A Texan steer will yield on an average 65 lb. of caul and suet fats, from which are obtained 28 lb. (43 per cent.) of oleo oil, 21 lb. (32 per cent.) of oleo-stearin, and 12 lb. (20 per cent.) of high-grade tallow. The chilled fat, after thorough washing from blood, is fed into hashers working at high speed, from which it issues through fine sieves into the rendering tank. No fat remains on hand longer than 14 hours, usually not more than four hours, before being rendered. The rendering tank is a steam-jacketed upright kettle of 2,000 to 5,000 lb. capacity, provided with revolving blades. Steam being let into the jacket, the hashed fat is continuously fed in, and kept in motion by the stirrer. When the tank is full, and the contents thoroughly melted, the temperature being 120° to 150° F., the fat is allowed to rest for the water and scrap to settle. The clear fat is drawn off from the top, and run into the graining or seeding cars of 400 to 600 lb. capacity. The temperature of the room in which

these cars are stored is maintained at 85° to 95° F., and the whole contents of the car will be in a semi-solid condition in from one to three days. This fat is free from all "greasy" taste. It is now taken to the press-room, kept at 70° to 80° F., where it is ladled out on a stout linen cloth, which is folded up ready for placing in the screw-press. When the press is filled, pressure is gradually applied, and the expressed oil constitutes the "oleo oil." This liquid fat is allowed to cool in barrels, and at ordinary temperature forms a soft, granular, tasteless and nearly colourless fat. The hard fat remaining in the filter bags forms the beef or oleo-stearin, which is used for making "refined lard" by the addition of cotton-seed oil, or is sold to the soap and candle maker.

The manufacture of "neutral lard" is conducted by essentially the same machinery and at about the same temperatures as for oleo oil, but only the leaf fat of freshly slaughtered hogs is used. A hog yields from 5 to 15 lb. of leaf lard, of which 100 lb. yields 90 lb. of "neutral." The screw-press is not employed to separate the stearin, but the melted fat is run directly from the rendering tank into a very strong iced brine, where it remains for 24 hours before being placed on shelves to drain. The "neutral" is a white, slightly granular, tasteless, solid fat.

The by-products of the oleo oil and neutral lard manufacture, namely, stearin, tallow, and lard, are standard merchantable articles. Only fresh and sweet fats are used, and great cleanliness is observed through all the processes. The vegetable oils employed are refined by ordinary methods, whereby a product of a light straw colour and bland taste is obtained. The butter used is always selected for its high flavour. The granular character of oleo oil requires the addition of a softer fat, such as neutral lard or cotton-seed or other vegetable oil, in order to approach more closely to the consistency of butter. The proportions in which these ingredients are used vary with the season of the year, the grade desired, and the formula of the manufacturers. The charge of milk or cream, however, is the same for all grades manufactured by any particular factory, and varies from 10 to 20 per cent. The milk or cream is allowed to become slightly sour.

The mixing of the materials to form the butter substitute is conducted in a steam-jacketed churn of from 1,200 to 2,500 lb. capacity. The oleo oil and neutral lard are melted in separate vessels at 90° F. The charge of milk or cream is first run into the churn, and the paddles are kept in motion until the butter begins to form. Then the oleo oil is added and stirred, next the neutral lard, and finally the annatto to give the desired colour. The butter is either added to the churn or worked in subsequently. The temperature is carefully regulated, beginning at about 85° F. and increasing gradually to 105° F. at the end of the operation, when the whole charge has the appearance of a yellowish creamy fluid. From 20 to 90 minutes are occupied in the churning. The finished charge is run into tanks containing chopped ice and constantly stirred, or is met by a stream of iced water as it issues from the churn, the object being to give the mass a fine grain by the sudden cooling. The chilled mass is then placed on wooden trays to drain. Here the salt is added and allowed to work itself in, which generally takes from 12 to 24 hours. The salted mass is then thoroughly worked by mechanical rollers to remove the buttermilk and water.

Oleomargarin is placed on the market either "solid packed" or in prints or rolls. Four grades are generally made, known as "dairy" and "extra dairy oleomargarin," "creamery," and "extra creamery butterine," the last two containing from 10 to 25 per cent. of the best creamery butter. In the lower grades from 25 to 60 per cent. of neutral lard, 20 to 50 per cent. of oleo oil, 5 to 25 per cent. of vegetable oils, and in some cases from 2 to 10 per cent. of butter, with 10 to 20 per cent. of milk or cream, are the proportions used. Some factories employ no vegetable oils in their oleomargarin, preferring to use a larger proportion of neutral lard with a small amount of butter to obtain the desired butter consistency. In the higher grades the proportions of oleo oil are reduced, the vegetable oils are discarded, and creamery butter is used to make up the charge.—G. H. B.

Preserving Green-Fodder with Carbon Bisulphide.

A. Grete. Chem. Zeit. Rep. 13, 97.

Two bricked silos ($1.8 \times 1.5 \times 1.6$ metres respectively) were filled with good clover, which was just about to bud, and two kilos. of carbon bisulphide gradually added with a hand syringe. The fodder was then covered with well fitting boards and some roofing-felt. No special pressure was applied. After six months the fodder was found to be absolutely free from mould, not a leaf being spoiled. Moreover, it had an agreeable odour, and was slightly acid. The cows took it readily and without the slightest ill-effects. An analysis also proved this means of preservation to be a good one, since almost the total crude protein substances originally present had remained unchanged. The author believes that it will be possible to prevent the fermentation of hay by carbon bisulphide, without spoiling it. Experiments on a large scale are being carried out, with a view of ascertaining the utility of this process.—A. R.

PATENTS.

Certain Improvements in the Manufacture of Butter, and in the better Flavouring, Colouring, and Preserving of the same, and in the Cleansing, Flavouring, Colouring, and Preservation of Rancid Butter, Margarin, and all other Artificial Butters, and Apparatus therefor. T. Adair, Belfast. Eng. Pat. 4495, March 24, 1888. 11d.

In applying this method, the cream is raised by heating, and after cooling is removed and placed in a bath of water and heated at 90° – 92° F. to melt the butter globules, while it is agitated to free the butter fat from the milk. The wash-water is then separated, preferably by use of the apparatus, which forms a part of the invention (drawings of which are given), and the process of washing repeated till the wash-water shows but a very slight opalescence. The butter so obtained is uniform in texture, colour and consistency, but without scent or flavour. To remedy this defect the butter is flavoured when at a temperature of 65° – 80° F., in the washing process, when a few drops of any essential oil, essence, or substance imparting an agreeable odour and taste to the butter, or preferably the purified butter essence, the preparation of which is described below, is added. At this stage also a little colouring matter, e.g., annatto, may be added if needful. In order to dissolve the casein which may be present in the melted butter fat, a little "albumen solvent," caustic lime, potash, or soda, is added, preferably when the wash-water has been drawn off, and before admitting fresh water.

Rancid butter and margarin are purified in the same way, by this process of washing the melted fat. In the case of rancid butter, the "butter essence" distils off and is collected from the top of the washing vessel, the butter fat being washed finally with water at 163° F., which drives off the last remaining odour of rancid butter. It is this distillate which is used for flavouring the fresh butter fat.

A press has also been devised for expelling the last of the water from the butter fat when cold, and consists essentially of a screw-press, with a compartment round it for maintaining the butter at a desired temperature while pressing, that recommended being 56° – 57° F. From the bottom of the press a series of needles pass automatically upwards into the butter, which opens it so as to facilitate the expulsion of the last portions of water from the butter.

Process for drying Organic Substances such as Potatoes and other Roots or Fruits. O. Inray, London. From G. Richter, Falkenberg, Germany. Eng. Pat. 6734, May 5, 1888. 6d.

THE potatoes, turnips, kohlrabi, or other produce, are peeled, then steamed, or boiled on a perforated sieve, the water is then run off, and the vessel exhausted of air until the potatoes, &c. cool down to 18° C.—J. M. H. M.

Treating Dangway Beans (Cassia tora, Cassia occidentalis) as a substitute for Coffee. Sir E. B. Sladen, London, R. McLeod and C. H. White, Burmah. Eng. Pat. 15,364, October 25, 1888. 4d.

THE seeds of *Cassia tora* or *C. occidentalis*, abundant in British Burmah, are ground and roasted and used like coffee.—J. M. H. M.

(B)—SANITARY CHEMISTRY.

Metropolitan Main Drainage. Sir H. E. Roscoe. Reports to the Metropolitan Board of Works.

1. *Deodorisation of Metropolitan Sewage at the Outfalls.*—In this report the proceedings taken in 1888 are recorded. Deodorisation was commenced at both outfalls, Crossness and Barking, May 7th, by the addition of 3 grains of bleaching powder to the gallon of effluent sewage, and continued until the stock of that material in hand (839 tons) was exhausted. After May 24th, at the northern outfall, and June 17th at the southern outfall, manganate of soda, in the same proportion, was added until July 11th, the weight used being 1,178 tons. The low temperature of the river water and the heavy rainfall had at that date materially improved the condition of the river. Deodorisation was resumed on July 16th, and continued until October 13th, 893 tons of manganate of soda having been used to deodorise about 52 million gallons of crude sewage discharged daily on the flood tide.

The value of the chemicals used in 1888 was 24,357*l.*, as compared with 42,467*l.* in 1887, a saving of 18,110*l.* (including a saving of 1,850*l.* due to reduction on the contract price of manganate of soda), whilst in 1887 a saving was effected of 38,604*l.* over the previous year. Thus the expenditure in 1888 as compared with the expenditure in 1886 shows a reduction of 56,700*l.* in this item of chemicals, without apparent deterioration of the river.

The use of manganate of soda without the addition of sulphuric acid in the proposed proportions was found not less effective on the putrescent matters of the sewage.

Concerning the effect of the manganate of soda on the general state of the river the author expresses the opinion that no amount of chemicals which can with any show of reason be added is sufficient, or nearly sufficient, to convert the whole of the fecal matter into harmless forms. One gallon of pure river water contains nearly four times as much oxygen as that supplied by three grains of manganate of soda (25 per cent.). The oxygen in the manganate is immediately consumed, both in removing the putrescent odour of the sewage and in preparing a condition of things favourable for starting a process of natural oxidation. This latter, however, involves the further supply of free oxygen, and this the river is called upon to contribute, inasmuch as the deodorised sewage contains none. Hence we can hardly look to the addition of the above quantities of chemicals for any improvement in the general condition of the river; rather must we seek for this improvement in some process of effluent aeration.

The purification of the river is chiefly effected by living organisms requiring free oxygen for their growth. These may be said to effect the changes generally ascribed to animal life. But other organisms of a vegetable character, such as algæ, &c., are always present in river water. These evolve oxygen during their life, and they are also potent instruments in the natural purification of the river; indeed, they are capable of oxygenating the water far above its normal amount, and thus aiding in supporting the life and growth of the former class of organisms. Both forms, therefore, assist each other in ridding the water of dead organic matter, both soluble and insoluble, and thereby bringing it into a healthy condition.

The author was not consulted as to the methods of chemical precipitation proposed to be used on a large scale, both at Barking and Crossness. If this can advantageously be adopted for the whole of the sewage of the Metropolis, and if, moreover, it should be proved practicable to carry out the whole of the sludge to sea, the author still leans to

the opinion, looking to the question of the *permanent* disposal of the sewage, that the sewage, whether previously clarified or not, must either be filtered through land, or discharged into the estuary at a point not higher than the sea reach.

The determination of dissolved oxygen in the river water, by a modification of Schützenberger's method as described by Dupré, is re-investigated by the author, who finds the source of error in the method is owing to the fact that when aerated water is introduced into an atmosphere of hydrogen (a necessary part of the process), the dissolved oxygen diffuses into that gas, and only a portion of the original oxygen is estimated. This portion is variable, and depends on the amount of exposure of the water to hydrogen gas, so that slight differences in the duration of an experiment may cause serious errors in the result. A method has been devised by which this error has been eliminated. This depends on the introduction of the water to be examined *beneath the surface* of a liquid containing a measured quantity of hyposulphite of soda, and a little reduced indigo carmine as an indicator.

Diagrams are given showing, in the form of curves, the amount of dissolved oxygen in the river water at Crossness at different periods of the year; the changes in the volume of fresh water coming into the river, as indicated by the quantity of sea salt present at low tide, the temperature, and the rainfall, and the conclusions adduced therefrom considered.

2. *The Chemical Examination of the Foreshores and Mud Deposits of the River Thames and its Estuary.*—It appeared to be of great importance in view of the proposal to carry the sludge out to sea, and of questions which may arise thereon, to be in possession of scientific data as to the condition of the foreshores of the Thames, from Barking down the river, to the mouth, including the whole of the estuary.

Samples of mud were collected at points where, in consequence of the set of tides, sewage sludge would, in the engineer's opinion, be most likely deposited on the foreshores and banks; and from Clacton, Walton-on-the-Naze, and Harwich, as positions which, in the judgment of competent persons, were those where sewage sludge would be found if it were discharged at sea, and should it then reach the shore. The investigation was made, with the assistance of F. Seudder, in September and October 1888. The samples divide themselves into two classes. First, those collected on the foreshores of the river proper, from Barking and Crossness down to Southend on the north, and Jenkin Sand on the south. Second, those on the estuary from Shoeburyness to Harwich on the north, and from Warden Point to Margate on the south, including two sandbanks known as "Little Sunk" and "Gimblect."

The Royal Commission stated a conclusion "that foul mud, partly composed of sewage matter, accumulates at Erith and elsewhere, and adheres to nets, anchors, and other objects dropped into it." This conclusion is also borne out by the well-known appearance of black patches of offensive matter in the river, which are at times raised to the surface. These are, without doubt, derived from sewage sludge which has settled down in the bed of the river and undergone putrefaction, whereby gases are evolved, which become entangled with the material and raise it to the surface. Analyses of 59 samples of the mud and deposits collected from the foreshore of *sections of the river of considerable length* were made, the average composition of which indicates that a gradual diminution occurs in the impurity of such deposits from the outfalls downwards. The reliability of four different means adopted for ascertaining the existence of sewage impurity in the deposits is considered in detail. These were:—1. The volatile matter. 2. The oxygen absorbed from potassium permanganate. 3. Percentage of nitrogen. 4. Phosphoric acid. The conclusion obtained from a comparison of all the numbers taken together is of distinct value as enabling one to obtain a general view of the relative chemical condition of the foreshores; and a table has been constructed to show the *average relative amount* of the organic impurity in various sections of the river and of the estuary. Taking the total values or average impurity of section 1 as 100, that of section 2 is 90, that of section 3 is 49, that of section 4 is

16, there being a total percentage loss of impurity in passing from the outfalls to Southend of 84 per cent. As a further proof that sewage impurity exists in the river deposits, the presence of manganese was detected in 8 out of 11 samples taken between Crossness and Erith, the manganese being derived from the manganate of soda which is added to deodorise the sewage before being discharged into the river at the outfalls.

The conclusions arrived at from the chemical examination are in the main borne out by the independent microscopical evidence obtained by the Board's chemist, which forms part of the appendix to the report. A large amount of detailed information is set out in tabular appendices, accompanied by a sketch map of the Thames and its estuary, on which is indicated, in the first place, the approximate position at which the samples were collected. Secondly, the four sections into which the river as far as Southend has been divided, with the relative amount of impurity in each section. Thirdly, a comparison of the purest sample from the sandbank "Little Sunk" (taken as the unit) with those collected at other points in the estuary, and also with the averages of the four sections of the river.

3. *Deodorisation of Sewer Emanations and on Sewer Ventilation.*—In a previous report (June 16, 1888), the author directed special attention to the necessity of ventilating the sewers, and to the advisability of removing all obstructions from the ventilators, thereby more fully utilising the available means of ventilation at command, and further called attention to the desirability of utilising a system of pipe ventilation in aid of surface ventilation. The total number of charcoal boxes or other obstructions to ventilation removed was 473.

In this report the author states "that in spite of the fact that all obstructions to the escape of sewer emanations have been removed, the number of complaints made during the past year in consequence of such removals was only 52, and those of ventilators which had always been opened were 35, as compared with 43 from open ventilators in 1887. These numbers, considering the large area covered by the Board's sewers, may be regarded as inconsiderable. Moreover, the majority of the complaints arise from districts in which noxious trades are carried on, whilst in purely residential districts few complaints occur. Many of these complaints have reference to the same ventilator, so that instead of there being 87 separate ventilators complained of, the actual number was 49. The system of pipe ventilation has been carried out to some extent. There is, however, a difficulty in obtaining in many cases the consent of the property owner to allow these pipes to be carried up the side of the premises, and it appears desirable that Parliamentary powers for this purpose should be obtained.

Experiments with liquid sulphurous anhydride used in the form of apparatus supplied by Messrs. Boake, Roberts and Company have been satisfactorily carried out in deodorising the emanations in the sewers on the Chelsea Embankment. They have shown that when it is desirable to deodorise the air in a sewer rapidly, the apparatus works well, and in such cases its adoption is strongly recommended.

The author is in accord with those who desire to see the general condition of house drains placed under public inspection, so that as the landlord is responsible for the structural safety, so ought he to be for the sanitary safety.

—F. S.

The Action of Artificial Colours on the Animal Organism. T. Weyl. Ber. 21, 2191.

Naphthol Green B. (Casella and Co.) is innocent, even in the stomach.

Manchester or Martius Yellow can be resisted by rabbits but is poisonous for dogs.

Naphthol Yellow S. is non-poisonous.

The Safranines are poisonous.

The Azo Colours. No azo colour has been observed to be poisonous.

Picric Acid, belongs to a group of poisonous nitro-colouring matters, as has been known for a long time.

Aurantia is poisonous and injurious to the skin of certain individuals, if indeed this selective action is not merely apparent and the difference really due to the appearance in the trade of two isomeric hexanitrodiphenylamines, the one like that prepared by the *Actiengesellschaft für Anilinfabrikation* in Berlin, being non-poisonous to rabbits, the other, like that prepared in Basel, been excessively injurious to the human subject.—W. S.

PATENTS.

Improved Means and Method of Precipitating and Disinfecting Sewage Matter. G. W. Bremner, London. Eng. Pat. 5861, April 19, 1888. 6d.

THE sewage is mixed with a precipitant as it flows into the tanks and is there charged with compressed air or oxygen alone or mixed with other gases, by air compressors and distributors; the tanks may have covers with ventilating shafts. The precipitants mentioned are the "*Piombina*" and "*Terra Gallia*" found among the volcanic debris of Mount Vesuvius, phosphate of alumina, lithomarge and other ferruginous substances, dissolved in hydrochloric, sulphuric, or nitric acid; manganese preparations of potash or soda; bleaching powder, black ash, chlorides or sulphates of potash, sulphates of soda. The phosphate of alumina may be prepared according to Eng. Pat. 13,761 of 1885. The sludge is pressed, dusted with some of the above materials in a dry form, to prevent loss of ammonia and to absorb moisture, and ground for manure.—J. M. H. M.

Improvements relating to Disinfectants. H. H. Lake, London. From C. H. Shaw, Brooklyn, U.S.A. Eng. Pat. 6407, April 30, 1888. 8d.

A CANDLE of sulphur is enclosed in a casing and is provided with fibres of combustible material distributed throughout its mass, and with transverse wicks laid radially on the upper concave surface of the candle, with turned-up ends.

—J. M. H. M.

An Improved Antiseptic Compound for Preserving Perishable Articles. W. H. Daniels, Chicago, U.S.A. Eng. Pat. 17,843, December 6, 1888. 4d.

THE compound consists of the following:—Sulphur, one pound; sugar, four ounces; sassafras, four ounces; cinnamon, two ounces; and potassium nitrate, two ounces. The ingredients are reduced to a fine powder and then mixed to form a homogenous mass. In using it, the substances to be impregnated are enclosed in an air-tight vessel together with some of the compound "which is vaporised by any suitable apparatus."—J. W. L.

Improvements in Sanitary Materials or Preparations for Preventing the Decomposition and Deterioration of Sizes, and Similar Finishes for Fabrics and the like, and for Preventing the Access of Infectious Diseases. R. Hannan, Glasgow. Eng. Pat. 3159, February 22, 1889. 4d.

"QUADRIBORATE of soda" (about 40 parts) and salicylate of soda (about 1 part) are mixed with 1,000 parts of solid gelatin, size or the like, and dissolved for use in sizing, the object being to prevent the mildewing of the materials, and also to disinfect such bodies as are in contact with the sized material.—J. W. L.

An Improved Insect Destroying Compound, and Method of preparing same. A. M. Clark, London. From E. Bean, Jacksonville, U.S.A. Eng. Pat. 3470, February 26, 1889. 4d.

CAUSTIC lime is slaked with water, and while slaking, powdered sulphur is added, the latter combining with the lime and forming a compound soluble in water.

About 2 lb. of sulphur are added to 8–10 lb. of lime, and the mixture finally made up with 100 gallons of water.

It is applied to plants and trees for the purpose of destroying insects.—J. W. L.

Improvements in Blotting Paper, and in the Manufacture of the same. J. Hawke, New Barnet. Eng. Pat. 4768, March 28, 1888. 6d.

THE inventor claims the incorporating or combining of salts of iron or sodium with the pulp, from which blotting paper is to be made, or the impregnating of the manufactured paper with solutions of the above, whereby the efficiency is increased.—E. J. B.

Improvements in the Construction of Apparatus for making Bisulphites or other Compounds used in the Treatment of Wood Pulp or other Fibrous Materials, and the like. I. S. and J. T. McDougall, R. K. Hartley, and T. Sugden, Oldham. Eng. Pat. 7060, May 11, 1888. 11d.

See under VII., page 392.

An Improved Process of Preparing or Treating Vegetable Fibrous Material for Obtaining Fibre therefrom. J. Mactear, Westminster. Eng. Pat. 12,682, September 3, 1888. 6d.

THIS invention consists essentially in submitting the fibrous material, such as flax, hemp, jute, reed, &c., to the action of ammonia in presence of sodium or potassium hydrate, carbonate or borate. The solution is heated and kept in circulation by means of live steam. The action of the alkaline liquid is aided by a current of electricity sufficient to decompose water, the evolved gases acting on the gummy matter of the fibres in such a way as to loosen and destroy it.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Chemical Composition and Toxic Action of Urechitis Suberecta. M. Egasse. Nouv. Rem. 1888, 555.

FROM *Apocynce Urechitis Suberecta* occurring in Jamaica, Bowrey isolated a crystalline and very poisonous glucoside urechitine, $C_{25}H_{45}O_{10}$, also a body resembling the glucosides termed urechitoxin, $C_{23}H_{29}O_5$, equally poisonous. Minkiewicz also found a resinous acid, smelling like vanillin. This acid kills cats in doses of 0.006–0.001 grm. per kilo. of animal weight, though no remarkable change was noticed in the dead body by autopsy. Solutions containing 0.002 per cent. of the glucoside contract the vessels of warm-blooded animals. Both the glucoside and the resinous acid are true heart-poisons. They are antidotes for curare, and closely resemble strophantus.

—A. R.

On α - and γ -Chloro-aceto-acetic Ethers. An Attempt to prepare Citric Acid Synthetically. A. Haller and A. Held. Compt. Rend. 108, 516–518.

BY the action of chlorine on aceto-acetic ether both the α - and γ -chloro-aceto-acetic ethers are produced. The latter is best obtained by passing dry chlorine into well cooled aceto-acetic ether contained in a broad vessel. The delivery tube should only be immersed to the extent of 3–4 cm. in the liquid. Chlorine is rapidly absorbed, and after about half an hour the weight of the ether has increased by 30 per cent., as required theoretically. The product is washed and rectified. The portion boiling at 188°–189° contains the most mono-chloro-derivative; a di-chloro-derivative is found in the fraction boiling from 195°–200°. By treating the former with potassium cyanide,

a mixture of the γ -chloro-derivative with a small quantity of the α -derivative is obtained. The product resulting from the action of the cyanide is dissolved in alcohol saturated with hydrochloric acid. When all the ammonium chloride has separated, the ether is treated with hydrocyanic acid, and then again with alcoholic hydrochloric acid. Finally an oil is obtained which distills in vacuo at about 200°. This after saponification yields a substance which has the characteristic property of citric acid, viz., the solution of its lime salt becomes turbid on heating and clear again on cooling.

—A. R.

On the Physiological and Therapeutic Action of o-Methylacetanilide. Dujardin-Beaumetz and G. Bardet. *Compt. Rend.* 108, 571—572.

THE *o*-methyl derivative of acetanilide known as "Exalgine" melts at 101°, is slightly soluble in warm water, very soluble in water to which a little alcohol has been added. Rabbits are killed by administering 0.46 grm. per kilo. of animal weight. In non-toxic doses it acts as an anæsthetic, and there is a progressive lowering of the temperature of the body. Compared with antipyrine, its action seems more thorough as an anæsthetic, and less so as an antipyretic. Quantities of about 0.5 grm. have very marked pain-killing effects in all cases of neuralgia. Hitherto its administration has not been followed by any of the unfavourable symptoms attending the use of antipyrine and acetanilide, with one exception. It eventually passes into the urine, and in cases of diabetes diminishes both the quantity of the urine as well as that of the sugar. "Exalgine" as an anodyne is superior to antipyrine. In conclusion, the authors briefly allude to the relations existing between chemical constitution and physiological and therapeutic effects of the various febrifuges. They ascribe antiseptic action to bodies of a phenolic nature (phenol, naphthol); febrifuges are nearly all amido derivatives, and finally anodynes are usually amido derivatives, in which one atom of hydrogen is replaced by a radical of the fatty series, notably methyl (*e.g.*, in antipyrine, acetphenetidine, exalgine).—A. R.

Hydrastin. M. Freund. *Ber.* 22, 456—459.

THE author has formerly (*Ber.* 20, 2400; this Journal, 1887, 381, 449, and 641) shown that hydrastinine, the decomposition product of hydrastin, when treated with potash, yields hydrohydrastinine, which is reconverted into hydrastinine by gentle oxidation. By oxidation with potassium permanganate in alkaline solution hydrastinine is converted into oxyhydrastinine. These reactions show that hydrohydrastinine, hydrastinine, and oxyhydrastinine bear the same relation to each other as an alcohol and its corresponding aldehyde and acid.

The behaviour of cotarnine with alkalis has also been investigated. The reaction does not proceed so smoothly as in the case of hydrastinine. The author has also failed to convert cotarnine by oxidation into a product of higher oxidation. Further experiments are in progress, however, in this direction.

On boiling together hydroxylamine hydrochloride, and hydrastinine in alcoholic solution, the corresponding oxime is obtained as chloride in beautiful crystalline plates. The hydrochloride is easily soluble in water; ammonia and sodium carbonate precipitate the free base; free alkalis in excess dissolve the base. It crystallises from alcohol in white needles, melting at 145—146° C. Its composition is $C_{10}H_{12}NO_2CH : NOH$. The platinum salt $(C_{11}H_{13}N_2O_3Cl)_2 PtCl_4$ forms as a crystalline precipitate on mixing solutions of the hydrochloride and platinum chloride.

Hydrastininehydriodide is formed by boiling hydrastinine with fuming hydriodic acid, or by precipitating hydrastinine hydrochloride with a solution of iodine in potassium iodide. It separates from dilute alcohol in splendid brown needles. Melting point, 132°—134° C. Dibromohydrastinine, obtained by the action of bromine vapour on hydrohydrastinine hydrobromide, crystallises from water in white, broad needles, melting at about 280° C. It is most probably a derivative of hydrastinine, of the formula $C_{11}H_9Br_2NO_2$.

Some time ago the author, in conjunction with W. Will (*Ber.* 19, 2802; this Journal, 1886, 677), described a neutral body obtained in small quantity from the root of *Hydrastis canadensis*. Further analyses have proved it to be meconin. The body obtained by the action of nitric acid on it is nitro-meconin.—H. T. P.

Constitution of Filicic Acid. E. Paternó. *Ber.* 22, 463—465.

DACCOMO (*Ber.* 21, 2970), who investigated filicic acid and a number of its derivatives, came to the conclusion that this acid is isobutyrylhydroxynaphthoquinone and its composition $C_{14}H_{16}O_5$. He prepared and analysed a compound $C_{14}H_{16}O(C_6H_5N_3H)_4$ by boiling the acid with phenyl hydrazine in ethereal solution. On treating an alkaline solution of the acid with zinc dust in the cold he obtained a yellow oil which rapidly oxidised and turned red on exposure to the air. The yellow oil he considered to be a reduction compound of filicic acid, probably $C_{14}H_{22}O_5$, and from an analysis of the barium salt of the red oxidation product he assigned to the latter the composition $C_{14}H_{22}O_{11}$.

The author severely criticises Dacomo's experimental results and theoretical conclusions. He points out that the composition of isobutyrylhydroxynaphthoquinone, which would be a neutral compound, is $C_{14}H_{12}O_4$, and draws attention to the fact that a hydroxynaphthoquinone or hydroxyhydronaphthoquinone derivative, which according to Dacomo takes up six atoms of hydrogen, would not be reduced so easily.

The compound $C_{14}H_{22}O_{11}$ could not possibly be formed, and Dacomo's analysis is worthless, as he overlooked the fact that some of the carbon remained as barium carbonate.

The author concludes by asking whether a hydroxynaphthoquinone could possibly combine with four molecules of phenylhydrazine, and states that in his opinion nothing is yet known of the constitution of filicic acid.—F. S. K.

Harmine and Harmaline. O. Fischer. *Ber.* 22, 637—645.

THIS paper is a supplement to a paper published four years ago by O. Fischer and E. Täuber (*Ber.* 18, 400) concerning the alkaloids of *Peganum harmala*. By the oxidation of harmine, a dibasic acid ($C_{10}H_8N_2O_4$) was obtained, from which, by separation of carbon dioxide, a base ($C_8H_6N_2$) resulted. Harmine takes up four atoms of hydrogen when treated with sodium and alcohol, and is converted into tetrahydroharmine. The latter substance forms interlaced needles, melting at 199° C. Its solution exhibits a faint bluish-green fluorescence, which is rendered more green by oxidising agents, such as ferric chloride or silver nitrate. A tetrabromoharmine, $C_{12}H_{12}N_2OBr_4$, has been formed. Sulphurous acid removes the bromine from this addition product. Alkaline carbonates have the same effect on warming, and even boiling alcohol reconverts the substance into harmine. Harmaline yields on reduction with sodium or zinc dust the same final product as harmine, namely, tetrahydroharmine. Harmalol is obtained as hydrochloride by the action of hydrochloric acid on harmaline. Harmine oxidised in glacial acetic acid solution with chromic acid yields harminic acid, $C_{10}H_8N_2O_4$. Harminic acid is also obtained from harmaline by a similar process. Harmine is produced by the partial oxidation of harmaline. Harminic acid yields on heating a beautiful crystalline base, apo harmine ($C_8H_6N_2$). Harmolic acid, $C_{12}H_{10}N_2O_5$, is produced by the fusion of harmol with caustic potash. It crystallises from hot water in small needles, which melt at 246°—247° C. with decomposition.

Many attempts were made to synthesise apoharmine or hydroapoharmine, but without success, nor are these substances identical with any known bodies of the same percentage composition, as for example Merz and Ris's tetrahydroquinoxaline, which not only possesses the same composition as dihydroapoharmine, but similar properties. (*Ber.* 20, 1190).—H. T. P.

Morphine. Nature, May 2, 1889, 14.

SKRAFT and Wiegmann have recently separated methyl-ethylamine, $C_2H_5(C_2H_5)NH$, from morphine, $C_{17}H_{19}NO_3$, itself long known to be a derivative of phenanthrene $C_{15}H_{13}$. Morphine may thus turn out to be an isonitrile of phenanthrene.

Morphine was heated for about five hours at $180^\circ C$. with 10 times its weight of a 20 per cent. solution of alcoholic potash. A volatile substance of an amine-like odour was evolved, and was driven over by a current of coal gas into sulphuric acid.

The filtered acid solution was then super-saturated with caustic soda and the purified amine distilled over by steam into a standard solution of hydrochloric acid, and the hydrochloride obtained was crystallised. Crystals also of a platino-chloride were obtained.—W. S.

Report on New Drugs and Fine Chemicals.

Merk's Bull. 2, 1—12.

Agaricic acid.— $C_{11}H_{17}(OH)(COOH)_2$. This substance is the active constituent of agaricin, which is itself obtained from *Fungus Laricis*. Pure agaricic acid melts at $138^\circ C$. and is but slightly soluble in cold water; more easily in hot water, from which solution the acid mostly crystallises out on cooling. Agaricic acid is equal to atropine in its action in suppressing dermic secretion.

Allyltribromide.— $C_3H_5Br_3$. This is identical with "Tribromhydrin." Wurtz obtained it by treating allyl iodide with bromine and Berthelot and Lucea by the action of phosphorus tribromide and pentabromide on glycerol. It is a slightly yellowish liquid of sp. gr. 2.130 at $15.5^\circ C$. and boils at $217^\circ C$. It is a strong sedative and anodyne, and is taken both internally and subcutaneously (Armand de Fleury).

Anagyrine. $C_{14}H_{18}N_2O_2$, is an alkaloid recently discovered by Hardy and Gallois in the leguminosa, *Anagris fatida*, the toxic properties of which were described by Arnoux in 1870.

The new alkaloid is a yellowish, amorphous substance, very hygroscopic, and soluble in water, alcohol, and ether. It forms salts which easily crystallise. It has powerful toxic action, ending in arrest of respiration and motion of the heart.

Chloral-Ammonium (Trichlor-amido-ethylie alcohol), $CCl_3CH(NH_2).OH$, is formed, according to Schiff, by the action of ammonia on a solution of chloral in chloroform.

Nesbit recommends the use of chloral-ammonium instead of urethane and chloral hydrate (Deutseh. Chem. Centr. 1888, 720). The reason for such substitution is that the action of the chloral hydrate on the respiration centres and the heart, is retarded by the introduction into that compound, of an amido-group.

Cineraria maritima.—The liquid extract of the juice of this plant, a native of Southern Europe and Central America, has been found of extraordinary efficacy in cases of cataract. The plant from which this extract was obtained was grown in Venezuela.

Condurangin.—This glucoside has been examined by Jukna of Dorpat. He found it to belong to that peculiar class of glucosides, the members of which are precipitated by a number of the general alkaloid reagents and by sodium chloride. It is a slightly yellowish powder, soluble in alcohol, and possessing an aromatic and bitter taste.

Condurangin influences neither the action of the heart nor the blood-pressure of warm-blooded animals, nor does it exercise any decomposing effect on the blood. It acts exclusively as a nerve poison, the influence of which seems to be confined to the brain and the medulla oblongata.

Coronillin. $C_{11}H_{12}O_5$, is a glucoside recently discovered by Schlagdenhauffen and Reeb in the European Papilionaceæ—*Coronilla scorpioides*. On boiling with dilute mineral acids coronillin is decomposed into glucose and coronillein. Coronillin is a heart-poison, whilst coronillein exercises no toxic action whatever.

Diphenyl methyl-pyrazole has been recently recommended as a substitute for antipyrine. It is distinguished from the latter by a very decided basicity and by a less distinct reaction with ferric chloride. It takes the form of white needles, melting at $150^\circ C$. with difficulty soluble in water, petroleum spirit, and ether, but with ease in alcohol and glacial acetic acid.

Eserine-Pilocarpine.—Researches by Ellenberger and Bass have recently demonstrated the eminently beneficial action of a mixture of pilocarpine with eserine (physostigmine) as a specific for the colic of horses. It is a white powder, very readily soluble in water, and is administered by injection.

Hedvigia Balsamifera is the name of terebinthinacea, native in the West Indies. In its alcoholic extract a resin and an alkaloid have been discovered, both possessed of toxic properties, those of the alkaloid being stronger than those of the resin. The aqueous extract of *Hedvigia balsamifera* is $2\frac{1}{2}$ times less powerful in its toxic action than the alcoholic; also the stem of the plant yields more toxic effect than the root.

Mercurthymol Salts.—(Mercurthymol acetate, -sulphate and -nitrate.) These salts have been found of great value in the treatment of syphilitic diseases.

The Acetate. $C_{10}H_{13}OHg—HgCH_3.CO_2$, has been most largely experimented upon. Like the other salts, it is crystalline, colourless, insoluble in water, but easily soluble in alkaline solutions. When administered subcutaneously it is prepared as an injection by suspension in liquid paraffin ($\frac{1}{2}$ grains to 15 grains of the paraffin). The salts were administered internally in pills.

There was no appreciable difference in the efficacy of the three salts named.

Phlorizin.—This glucoside is found in the bark of the apple, pear, plum-, and cherry-trees, especially in the root-bark. Mering, in 1885, discovered the fact that this glucoside given to dogs, causes intense *Mellituria* without otherwise affecting the animal's general health. Further researches (*Zeits. für klinische Med.* 1888, 405) have demonstrated relations of remarkable interest existing between the effects of Phlorizin and *Diabetes mellitus*. In short, it had hitherto been assumed that artificial diabetes could not be induced in an organism where the liver was devoid of glycogen, but Mering's researches have shown that intense *mellituria* may be induced by doses of phlorizin in the body of an animal whose liver and muscles are both totally devoid of glycogen.

Pyridine. C_5H_5N , is easily miscible with water in any proportion, and the aqueous solution shows an alkaline reaction. It is also miscible with alcohol, ether, benzene, and the fatty oils. When pure, it is strongly hygroscopic, readily attracting sufficient moisture from the atmosphere to slightly increase its specific gravity and greatly depress its boiling point.

Of the well-crystallised salts which it forms, the two following are used for internal application:—

Pyridine nitrate. $C_5H_5N.HNO_3$.—Slender, colourless needles, easily soluble in water, less so in alcohol.

Pyridine sulphate (C_5H_5N) $_2.SO_4H_2$.—Crystalline; soluble in all proportions in water and alcohol.

Distler found that pyridine is but very slightly toxic. Penzhoid found that pyridine acted as a general antiseptic, especially as regards *Myceles*. It appears that taken by inhalation pyridine acts as a respiratory sedative. It is successfully used as a topical antiseptic in diphtheria, also as a heart-stimulant.—W. S.

The Active Principle of Condurangin Bark. R. Kobert. Chem. Zeit. Rep. 13, 58.

There are at least three active substances, viz., two or three glucosides and a resin, which are all similar in their action.

The *Condurangin* of Vulpus is also not a simple substance, but a mixture of two of the above glucosides. It is observed that when its solution is heated to $40^\circ C$. it

coagulates like albumen, and it resembles this substance also in being precipitated when the solution is saturated with sodium chloride. Hot filtered solutions therefore contain very little or no conduragin.

Conduragin possesses marked poisonous action on the central nerve system. It interferes with the animal movements, destroys the appetite, produces a strong flow of saliva and vomiting. On the heart, blood-vessels, blood, &c., it is without action. The fatal dose for flesh-eating animals is 0.02 grm. for every kilo. of animal weight, and for the herbivorous about three times this amount.—A. W.

PATENTS.

Improvements in the Production of Mercury Compounds.

L. Merck and E. Menzel, Darmstadt, Germany. Eng. Pat. 3094, February 29, 1888. 6d.

This patent relates to the production of a somewhat unstable group of compounds, of which the thymol derivatives $C_{10}H_{13}OHg.HgNO_3$ and $C_{10}H_{13}OHg.HgC_2H_3O_2$ may be taken as typical. Similar derivatives can be obtained from phenol, resorcinol, β -naphthol, and other mono- and polyhydric phenols, and from mercuric salts other than the nitrate and acetate. They are prepared by adding a warm acid solution of the mercuric salt gradually, and with vigorous agitation, to a warm alkaline solution of the particular phenol until the precipitate barely redissolves. When the liquid cools, the mercury compound separates in a crystalline form, and can be purified by recrystallisation from a dilute solution of an alkaline hydroxide. These compounds are only slightly soluble in dilute acids, and are therefore precipitated when their solutions in alkalis are acidified.—C. H. B.

An Apparatus for the Extraction of Oxygen and Nitrogen from the Atmospheric Air. A. Brin, London. Eng. Pat. 3967, March 14, 1888. 8d.

This apparatus consists essentially of a cylindrical iron retort turning upon rollers at each end, and divided by vertical partitions into a number of compartments containing oxide of barium. Provision is also made at each end of the retort for the inlet or outlet of gas, and the upper and lower part alternately of each partition is perforated with a large number of small holes to facilitate the passage of gas throughout the retort. This latter is protected as to its exterior surface by a coating of asbestos and silicate of potash or soda, and is placed over a furnace so arranged that the heating is performed by carbonic oxide only. The heated products of combustion also generate steam for working fans or pumps to drive air through the retorts, or to produce a vacuum when it is desired to extract the oxygen from the peroxide of barium. An automatic lever arrangement worked by the expansion of the retort, regulates the supply of carbonic oxide and prevents the retort from becoming overheated.—A. R. D.

fogs the plates, even if the exposures were made in exceptionally bad light, as plates have been in this bath 8—9 hours without being fogged. Moreover it can be used for several successive plates. It can be preserved without alteration in stoppered bottles in the dark. Where it is desirable to accelerate the development, a little carbonate of soda should be added to the bath.—A. R.

PATENTS.

A Process of Photographing in Colours. J. B. G. Bonnaud, London. Eng. Pat. 4537, March 24, 1888. 6d.

TRANSPARENT negative and positive images of the object are prepared, and a glass plate is coated with a mixture of sugar or gum and potassium bichromate, dried, and exposed to light under the transparent positive for a sufficient length of time. The darker tints of the object are then applied in the form of finely-powdered vegetable colours, exactly as in the ordinary "dusting on" process. The plate is again dried if necessary, and now exposed to light under the transparent negative, which is reversed in order that the different parts of the image may correspond. When sufficient exposure has been given, the lighter tints are applied in the same manner as the darker tints, and the image is afterwards coated with boiled oil and varnish mixed with 10 times their weight of turpentine. Details may then be painted in with ordinary oil colours. The picture is next coated with collodion prepared by dissolving 2 grms. of pyroxylin in 40 cc. of alcohol of 62°, and 60 cc. of ether of 40°, and after a few minutes washed with water in order to remove all soluble matter. It is then placed for not more than a minute in a cold filtered solution of 20 grms. of soap and 20 grms. of bleaching powder in a litre of water, again washed, and then transferred to canvas, wood, or any other support. If it be desired to imitate an oil painting, the support is first coated with white paint, and the finished picture then shows brush marks. When a water-colour drawing is copied, treatment with oil and varnish is omitted.—C. H. B.

Improvements in the Production of Collodion Photographic Films or Surfaces of exalted Sensitiveness. R. Norris, Aston. Eng. Pat. 7044, May 11, 1888. 6d.

THE object of these improvements is to obtain collodion plates equal in sensitiveness to gelatin plates, and the improvements are carried out in several different ways. In the method which the author terms the alkaline-bath process, 7 grains of pyroxylin made at about 200° F. are dissolved in a mixture of 1 drachm of alcohol and 2 drachms of ether, and gradually mixed with a solution of 26 grains of silver nitrate in 80 drops of glycerol and 5 drachms of alcohol. The glycerol may be omitted and a larger quantity of alcohol used. The argentised collodion is spread upon glass or other suitable support, which is then immersed for 5 to 45 minutes in a solution of an alkaline iodide, bromide or chloride, or a suitable mixture of these salts, a small quantity of alcohol and ether being added to this solution with a view to gain increased sensitiveness. The temperature of the bath should be about 76° F. A haloid silver salt or a mixture of such salts is formed in the film, and during immersion changes from the molecular modification which transmits ruby light to that which transmits green and blue. The plate is then well washed, immersed for some time in a dilute solution of an alkaline hydroxide or carbonate, and afterwards in a solution of gelatin containing about two grains per fluid ounce. It is then placed for about 15 minutes in a dilute solution of an alkaline iodide or bromide, and finally washed with water. It may now be used as a wet plate, or may be treated with any of the well known organic preservatives and dried.

In the acid-bath process the plate or other support is coated with collodion containing a soluble chloride, bromide or iodide, and is immersed in a solution of silver nitrate

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Sodium Sulphite as a Developer. P. Poiré. Compt. Rend. 108, 513.

BATHS prepared with pure sulphite develop more slowly than those in which commercial sulphite of soda has been employed, the cause being that the latter always contains some carbonate. The author recommends a solution containing 25 per cent. of pure sulphite and 1—1½ grms. of pyrogallie acid. Though slowly developed, the image gradually acquires the desired intensity. This bath never

containing a large proportion of nitric acid and saturated with silver iodo-nitrate, bromo-nitrate or chloro-nitrate. These latter substances are prepared by saturating a hot solution of silver nitrate with silver chloride, bromide or iodide and allowing it to cool, when the so-called iodo-nitrate, &c. crystallise. The sensitising bath may contain in each fluid ounce 70 grains of silver nitrate and 80 minims of nitric acid. After immersion in this bath the plates are washed and may be used as wet plates or treated with a preservative and dried. The degree of sensitiveness obtained depends on the temperatures of the baths and the times of immersion.

The sensitiveness of collodion emulsion plates may be increased in a similar manner. In the case of emulsions prepared with an excess of bromide the plate is washed and then treated with the alkaline solution, gelatin and the iodide solution in the manner already described. Emulsions in which the silver nitrate is in excess must be prepared with the iodo-, bromo- or chloro-nitrate, washed and then treated with the gelatin and iodide solutions. In both cases the emulsion plates are treated with a preservative. In the preparation of the emulsions, alkaline bromides give greater sensitiveness than bromides of the heavy metals.

These plates are exposed, developed and fixed in the ordinary manner. It is claimed that they are equal to gelatin plates in sensitiveness, and that the operation of washing and drying can be carried out much more rapidly.

—C. H. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Report of the French Commission for Explosive Substances on the Use of Explosives in Presence of Fire-damp.
Ann. des Mines, 5, 1888, 197—376.

The authors having satisfied themselves, both from the results of previous investigations and in some preliminary experiments, that mixtures of coal-dust and air were not as dangerous as mixtures of marsh-gas and air, have restricted themselves to the latter and more dangerous mixture. The experiments were conducted in a boiler which by suitable arrangements could be completely filled with a gaseous mixture of known composition, and the explosive under examination was suspended in the middle of the boiler and fired by the aid of electricity, the effect on the gaseous mixture being ascertained by the alteration in pressure observed on a pressure-gauge.

The marsh-gas was prepared from sodium acetate and soda-lime and stored in a gasometer; it contained per cent. 10.8 of air, 7.9 absorbed by bromine, no carbonic anhydride, and 81.3 of methane (by difference). The mixture introduced into the boiler contained generally about 10.3 per cent. of methane; this approximates to the most explosive mixture, whilst a 6 per cent. mixture verges on the limits of non-inflammability.

The first series of experiments were tried with unconfined explosives freely suspended in the gaseous mixture, this being the most dangerous condition; such experiments are useful to ascertain the actual safety of an explosive.

The explosives investigated were:—*Ordinary powder*. Dynamite containing 75 per cent. of nitroglycerol and 25 per cent. of silica. *Pandilles ammoniacal dynamite*, a mixture of varying proportions of nitroglycerol, ammonium nitrate, and of a carbonaceous substance destined to utilise the excess of oxygen produced by the detonation of the nitroglycerol and ammonium nitrate. *Gun-cottons* of the general formula $C_{24}H_{40-2n}N_8O_{20+2n}$ the maximum value of n would be 12, but in practice it does not exceed 11. The following table represents the number of cubic centimetres of nitric oxide evolved from 1 grm. of the various gun-cottons when examined by Schloesing's method; the value of n indicates the composition:—

	$n =$	Cc. N_2O_4
Endecanitric cotton.....	11	244
Decanitric ".....	10	203
Enneanitric ".....	9	190
Octonitric ".....	8	178
Heptanitric ".....	7	162
Hexanitric ".....	6	146
Pentanitric ".....	5	128
Tetranitric ".....	4	108

Military gun-cotton (205 cc. N_2O_4) corresponds approximately to the decanitric; *mining gun-cotton* (193 cc. N_2O_4) to the enneanitric; and a third gun cotton (173 cc. N_2O_4) investigated, to the octonitric. Tests were also made with *blasting-gelatin* consisting of gun-cotton and nitroglycerol and with *dynamite gelatin* consisting of blasting gelatin mixed with some such substances as a mixture of potassium or sodium nitrate with charcoal or sawdust. All these when detonated completely under the above conditions generally ignited the gaseous mixture, and must therefore be regarded as dangerous for use in mines where fire-damp may be expected. The last two compositions did not detonate completely in cold weather. Dynamite and also gun-powder even ignited the gaseous mixture when detonated in a Sottle's water-cartridge. *Hellhoffite*, a mixture of dinitrobenzene with $1\frac{1}{2}$ or $2\frac{1}{2}$ times its weight of nitric acid, made on the spot where employed, is anyhow not considered sufficiently convenient for use in mines; *Favier explosive*, 9 parts of mononitronaphthalene with 91 of ammonium nitrate; and *Bellite*, about 20 parts of dinitrobenzene and 80 of ammonium nitrate; these three explosives either did not explode at all, as was the case with the first two when freely suspended in air, or exploded incompletely, as in the case of bellite. Under exceptional circumstances finely-pulverised Favier explosive was made to explode and then ignited the gaseous mixture; the detonating mixtures used with this explosive is however of itself dangerous. Two powders consisting of gun-cotton and barium nitrate ignited the gaseous mixture, whilst a powder consisting of 60 parts of gun-cotton (175 cc. to 185 cc. N_2O_4), 30 parts of barium nitrate, 6 parts of saltpetre, 3 parts of gelose, and 1 part of paraffin, only inflamed the gaseous mixture twice out of 14 times. Various experimental mixtures were now investigated. Dynamite with an equal weight of either crystalline sodium carbonate, sodium sulphate, ammonia alum or ammonium chloride did not ignite the gaseous mixture, but with larger proportions of dynamite the ignition of the fire-damp generally ensued. Some interesting experiments were made with mixtures of coal-dust and dynamite. Three coals, containing respectively 40, 27.86 and 23.60 per cent. of volatile matter, mixed with equal weights of dynamite, did not set fire to the marsh-gas when exploded, even a mixture containing 4 of dynamite to 1 of the first coal in one experiment did not ignite it, but a mixture of 2 parts of dynamite with 1 part of a lignite (braunkohle) containing 62.4 per cent. of volatile matter, ignited the inflammable gaseous mixture. Mixtures of 20 of dynamite with 80 of ammonium nitrate detonate freely in the air without causing ignition of the marsh-gas; in this case both substances explode, but the temperature of the explosion of ammonium nitrate is lower than that of the dynamite, and therefore moderates the activity of the latter in the mixture. Mixtures of gun-cotton and ammonium chloride require so much of the latter to make them safe that they ultimately cease to explode at all.

Mixtures of gun-cotton and ammonium nitrate become safe when the former giving 173 cc. of N_2O_4 does not constitute more than 20 per cent. of the mixture. From these experiments it was concluded that simple explosives susceptible of igniting fire-damp will always fire gaseous inflammable mixtures, but that it is possible to produce binary explosives in which the temperature of detonation is sufficiently reduced to be safe.

It is pointed out that although the temperature of ignition of marsh-gas is $650^{\circ}\text{C}.$, the ignition is greatly retarded by admixture with another gas such as air or even oxygen; the retardation amounting to 12 seconds even if the temperature of the whole volume of gas is at 650° , whilst at lower temperatures it is still longer. It is for this reason that the immense temperature developed by an explosion does not ignite fire-damp, for this temperature is reduced with such great rapidity, some thousandths of a second, that there is not time to ignite mixtures of fire-damp, unless the initial temperature is sufficiently great—according to the observations of the present investigators about $2,200^{\circ}$ or over.

It is interesting to note that explosions not igniting fire-damp will ignite mixtures of coal-gas and air, these having a lower ignition point, and explosions igniting neither marsh-gas and air, or coal-gas and air, may ignite a mixture of hydrogen and air. The heat generated by

explosives is next studied, and methods and formulæ are given for its calculation. Calorimetric experiments with various explosives freely suspended in the air yielded results, some of which are tabulated below.

Wherever the heats found coincide with the theoretical, complete detonation has ensued, and therefore these results confirm and explain the behaviour of the various explosives already noticed. In explanation of the apparent anomaly of the lower nitrated gun-cottons giving higher temperatures than the more strongly nitrated ones, it is shown that the proportion of combustible gas in the gaseous mixture produced by the detonation increases as the proportion of nitrogen in the cotton diminishes, therefore the lower nitrated cottons should yield a more inflammable mixture which by its combustion would produce a great increase in temperature and might even account for those temperatures which exceed the theoretical in the above table.

† Allowing for complete combustion of the dynamite and simple dehydration of the alum.

‡ Complete combustion of dynamite, and decomposition of ammonium chloride into $\text{HCl} + \text{N} + \text{H}_2$.

A similar behaviour is observed with mixtures of gun-cotton and barium nitrate. A gun-cotton indicating by titration 180 cc. of N_2O_2 always ignites marsh-gas, because the temperature of detonation, about $2,000^{\circ}$, is increased by the combustion of the inflammable gas produced by the detonation; whereas the pyroxylin powder containing 60 per cent. of this gun-cotton, 30 per cent. of barium nitrate, and 6 per cent. of potassium nitrate ignites marsh-gas only exceptionally, owing, it is suggested, to the oxygen supplied to the mixture in the form of nitrates being sufficient to burn enough material so as to dilute the gaseous mixture produced by the detonation and render it non-inflammable; but by adding more barium nitrate, so as to provide enough oxygen to consume all the gas and admitting the subsequent dissociation of the carbonate, the temperature of detonation is raised to $2,550^{\circ}$, which is sufficiently high to ignite fire-damp. With regard to force

it is shown that the same amount of power may be produced at a lower price by the use of larger quantities of dynamite and ammonium nitrate than by employing smaller quantities of the more expensive dynamite.

Irregularities in explosives, such, for instance, as incomplete detonation, which produces indefinite reactions, are a source of danger, and are more common in mixtures than in simple explosives. These reactions vary under different circumstances, such as the amount of fulminate used for detonation, the temperature of the charge at the time of explosion, &c., therefore an explosive should not be considered safe if amongst its several modes of detonation in the open air there be one susceptible of igniting marsh-gas. The most suitable substance for reducing the temperature of detonation of an explosive is ammonium nitrate, as other substances, such as sodium carbonate, or sulphate, or alum, or ammonium chloride, only decompose partially, and their

effect is uncertain. Mixtures worthy of further consideration are: the pyroxylin powder; gun-cotton (173 cc. N_2O_5) with 80 per cent. of ammonium nitrate, giving a force of 7,550 grms. and a detonating temperature of 1,920; dynamite, with 80 per cent. of ammonium nitrate, f. = 6,260 grms., t. = 1,500; bellite, f. = 2,993 grms., t. = 2,186; Favier explosive, t. = 2,120°. The last two require to be further experimented with. Ammonium nitrate reduces regularly, as the proportions of it in the mixture increases both the temperature and power of dynamite and highly-nitrated gun-cotton; but with octonitric gun-cotton these reductions do not set in until 70 per cent. of nitrate is present. Curves illustrating this behaviour are given in the report.

Experiments were now made with the more dangerous explosives confined in tubes of lead or tin, closed below and open at the top. The explosive was placed and rammed in the tube, on a plug of marl or sand 5 to 6 centimetres thick. It was then tamped with clay or sand, or, in some cases, coal-dust, to the thickness of 10 to 12 centimetres. Tubes of various thicknesses were used, and exploded, as in the previous experiments, in the boiler. The portion of the tubes surrounding the explosive was blown to powder, whilst the upper and lower portions were generally found nearly intact at the bottom of the boiler. The following table of results illustrates the effect of the thickness and quality of the tube on the temperature of explosion:—

Explosive.	Description of Tube.		Material.	Effect on Mixture of Marsh-Gas and Air. I. = Ignition. N. = No ignition.
	Diameter.			
	Internal.	External.		
	Mm.	Mm.		
Dynamite.....	27	40	Lead	N.
“	30	40	“	I.
“	30	35	“	I.
“	25	40	Tin	N.
Mining gun-cotton.....	32	42	Lead	N.
“ “	30	35	“	N.
Blasting gelatin	25	40	Tin	I.
Dynamite gelatin	27	40	Lead	N.
Ammoniacal dynamite	25	40	Tin	N.

Other conditions being the same, the safety of the explosion increases with the thickness of the tube, owing, it is assumed, to the fact that much of the heat of detonation is converted into mechanical force, and so the temperature is reduced below the dangerous limit. Dynamite loses more than one-third of its initial heat of detonation in shattering the tube, and distributing the debris. To ascertain the effect of the density of a charge, the explosive was enclosed in a thin glass tube, and fixed by wads between the clay plug and tamping in the metal tube so as to leave an annular space between the metal sides of the tube and the exterior of the glass tube. Under these circumstances it was observed that the work done on the tube was greatly diminished, owing, it is suggested, to expansion of the gases within the tube, and instead of one-third, only one-fifth of the initial heat of the detonation of the dynamite was absorbed. The same result is observed with loosely packed explosives: for example, dynamite simply poured into a 32—42 mm. lead tube, and tamped, ignited fire-damp, whereas under the same conditions with the dynamite rammed in, no ignition ensued. This shows the importance of ramming and tamping well when using explosives. Altering the shape of the tube simply varies the work imposed on a unit volume of gas, the larger the proportion of surface, the greater the imposed work, but does not affect the density of the charge. Further experiments show that dynamite alone or mixed with 80 per cent. of ammonium nitrate, or 33 per cent. of ammonia alum, or 40 per cent. of ammonium chloride; bellite; pyroxylin powder (Moulin-Blanc); and gun-cotton (173 cc. N_2O_5) mixed with even 40 per cent. of ammonium nitrate, explode completely when confined in 25—40 mm. tin tubes, bellite, even in a 30—35 mm. lead tube; but blasting gelatin requires a stronger tube to ensure its complete detonation.

With regard to modes of igniting the charge. In using a fuse (Bickford) care must be taken not to place it in contact with the explosive; for under such circumstances gas and

flame may be projected through the tube into the external air, and so produce ignition of the fire-damp. Other objections to the Bickford fuse are the uncertainty of its composition, and the danger attached to lighting the exposed end. When electricity is used, preference should be given to currents of low tension so as to avoid sparking, and possible ignition of fire-damp. Detonating cords made of gun-cotton have been found uncertain. Lauer's friction cap has not yet been investigated by the Commission. Various detonators have been examined, and with the exception of those of Ruggieri and Scola, and ordinary 1.5 grm. fulminate caps, they do not ignite mixtures of marsh-gas and air when exploded by themselves. Strengthened fulminate caps differ from the ordinary ones chiefly in being made of stouter metal, and having the fulminate more compressed, and covered by a little metallic plate with a hole in the centre to allow access of fire; the gases from the explosion of these caps have therefore more work to do, and lose temperature, and consequently a strengthened 1.5 grm. cap, as might be presumed by the above hypothesis, does not ignite a mixture of either marsh-gas or even coal-gas and air, but does ignite a mixture of hydrogen and air; a larger charge, however, 5 grms. for instance, produces sufficient heat to ignite fire-damp. By imposing more work on the gases of detonation of an ordinary fulminating cap, a similar effect is produced. Thus by winding fine copper wire closely round the outside of an ordinary 1.5 grm. cap, this ceases to ignite fire-damp when detonated.

The conclusions arrived at have already been mentioned above, but special stress is laid on the importance of making the explosive do as much work as possible, and bearing in mind the uncertainty attached to the use of even the safest explosives, on the advisability of avoiding their use in presence of inflammable mixtures of marsh-gas and air, in fact the selection of the safest explosive "ought to be considered as diminishing the danger of explosion considerably; it ought not to be regarded as suppressing it absolutely."

Binary mixtures of ammonium nitrate with dynamite, or gun-cotton, or dinitro-benzene are recommended from a point of view of safety, although it is suggested that experiments should be made on the method of manufacture of these mixtures, on their durability, and on their behaviour in mines. All results of the numerous experiments are tabulated, and notes containing interesting theoretical considerations are appended, in which are given methods of calculating the force and temperature obtainable from explosives, and the results of such calculations are also tabulated. An objection to the use of water cartridges is the large bore-holes required.

Subsequent to the drawing up of the above report further experiments were made, using a mixture of coal-gas and air instead of marsh-gas and air, thus avoiding the expense of the manufacture of marsh-gas. The most explosive mixture of coal-gas and air contains 15 to 16 per cent. of the former; in the experiments it was more convenient to use a mixture containing 10 per cent.; the ignition temperature of this mixture appears to be about 2,100°. This was ascertained in the same way as the ignition temperature of marsh gas and air, namely, by exploding in it various cartridges of which the temperature of detonation, &c. could be calculated; the cartridge giving the lowest temperature and igniting the mixture being the one selected for fixing roughly the ignition temperature of the mixture. This mixture of gas and air is not much more inflammable than marsh-gas and air, therefore it is considered that it would not be too severe a test to make all explosives destined to be employed in presence of marsh-gas satisfy the condition of not igniting such a mixture of coal-gas and air when detonated while freely suspended in it.

In the first report it was suggested that moistness of the atmosphere aided the explosion of fire-damp, but further experiments have not confirmed this suggestion.

Remarks as regards dynamite are not altered in the second report, but as regards gun-cotton it is shown that although the gases from octonitric cotton burn in the air when the cotton is exploded unconfined, nevertheless when this explosive is confined in a tin tube, 25 mm. internal diameter, 31 mm. external, or thicker, not only does the gas not burn, but also the detonation is incomplete. By testing mixtures of dynamite and ammonium nitrate containing from 90 to 40 per cent. of the latter, it is shown that detonating power increases as this proportion decreases, and complete detonation of the unconfined mixture does not take place until 50 per cent. of dynamite is reached;

even increasing the amount of fulminate used with the 20 per cent. dynamite mixture scarcely improves the extent of detonation; in a 25 mm. × 31 mm. tin tube the condition of affairs is not much better, but in a 25 mm. × 40 mm. tin tube complete detonation of both dynamite and nitrate ensues. The gases evolved from this mixture do not react on one another; the same is the case with mixtures of dynamite and alum, ammonium chloride, &c., it is suggested that in such mixtures the non-explosive constituent, the one absorbing heat on decomposing, is decomposed only slightly, or not at all, during the propagation of the explosive wave; their decomposition only taking place in a closed tube. Various mixtures giving gases which react on one another were examined, such as mixtures of ammonium nitrate with combustible substances, gun-cotton, dinitrobenzene, ammonium picrate, naphthalene tar, heavy coal-oils, colophony, &c. In the open air they behave sometimes as if the explosive wave excited at one point exhausted itself before traversing the whole mass of the explosive; at other times, as if the explosive wave passed through the whole mass of the explosive, but stopped at the decomposition of the explosive constituent or constituents, the gases evolved being dispersed before reacting mutually; therefore, the detonation in the open air is incomplete. When, however, the gases are confined, as, for instance, when the explosive is put in a sufficiently strong metal case, then the reaction between the gases takes place, and the effect of a complete detonation is obtained. There are numerous results, tabulated, illustrating these points:— Mixtures of about 80 per cent. of ammonium nitrate with gun-cotton, or 83 per cent. with dinitrobenzene, do not detonate completely either in the air or in thin (25 × 31 mm.) tubes, but do in 25 × 40 mm. tubes. Mixtures of ammonium nitrate and picrate in the open air give an effect equal to the decomposition of the nitrate, but in the tube the result is equal to the decomposition of both. With tars, &c. the result is never much above that attributable to the ammonium nitrate.

Experiments were now made with increasing quantities of safety mixtures to test their capability of igniting the inflammable gaseous mixture; the various results are tabulated and discussed. In the following tables is given various data relating to the mixtures which proved safe; other mixtures already referred to are either too expensive or inconvenient, or improper as explosives as far as the present results indicate.

	Force in Kilos.	Heat from 1 Kilo. in Cals.	Grms. of Fulminate required for Detonation.

12½ of dinitrobenzene 87'5 " "	8'000	1'006	1'50
10 " 90 " "	6'700	750	1'50

* About octonitric.

Other mixtures worthy of consideration are those containing mononitronaphthalene, or naphthalene, and ammonium nitrate, but their behaviour is at present uncertain. Finally, attention is called to mixtures of ammonium copper nitrate and ammonium nitrate. The heat of formation of this salt N_2O_5CuO , $4 NH_3$ is for $(N_6 + H_{12} + O_8 + CuO)$ 164'1. The products of decomposition have not been studied, but the mode of disengaging most heat is as follows:—

disengaging 516 cals. per kilo. When exploded in the air white fumes of ammonium nitrate and of oxides of nitrogen are evolved; therefore products are uncertain. Its complete combustion by ammonium nitrate is represented by the following equation:—

$Cu(NO_3)_2, 4 NH_3 + NH_4NO_3 = 4 N_2 + 8 H_2O + CuO$, or proportions of 76 to 24 of nitrate, heat produced per kilo. = 655'5 cals., whilst the force = 6'090 kilos., and temperature of detonation 1,750°. This was therefore

considered as an interesting explosive in connexion with safety in fire-damp. In the open air or in tubes the detonation of the salt does not appear complete according to the above equations, either alone or when mixed with ammonium nitrate; in fact, is almost arrested in the open air when the nitrate present is double the copper salt. It is believed it would explode completely in a mine bore-hole; with regard to its safety the results are very satisfactory, even with mixtures containing only 25 per cent. of nitrate, but the mixture containing 80 per cent. of nitrate is safe in coal-gas, detonating at a temperature of 1,300°, with a force of 5,500 grms.

In conclusion they point out that safety mixtures of dynamite and ammonium nitrate should not contain less than 80 per cent. of the latter. The other mixtures must fulfil the conditions of having a temperature of detonation lower than 2,200°, of not yielding combustible gas after complete detonation, of having sufficient force to avoid use of larger quantities of the explosive, of being sufficiently explosive to minimise misfires, of being kept sufficiently long without undergoing change, and they must not be too expensive. Mixtures fulfilling these conditions more or less are those with ammonium nitrate, and (1.) A maximum of 75 per cent. of ammonium copper nitrate; (2.) 6 per cent. of naphthalene; (3.) 15 per cent. of octonitric gun-cotton; (4.) 10 per cent. of mononitro naphthalene; (5.) 10 per cent. of dinitrobenzene. They recommend trials in mines.

To avoid danger as much as possible, the mixtures should be well mixed, and the smallest proportion of the dangerous substance, consistent with efficiency, should be used.

As safety depends on the instantaneous admixture of the gas of the detonation with the surrounding atmosphere, it is therefore dangerous to blast with a large quantity of explosive in a confined space.—D. A. L.

Report on Further Experiments with Explosives at the Experimental Level of the König Colliery, near Neunkirchen (Saarbrücken), in Respect to their Behaviour with Fire-damp and Coal Dust. H. Lohmann. Zeits. f. Berg., Hütten-und Salinwesen, 1889, 83.

An explosive consisting of a mixture of dynamite with 40 per cent. of soda crystals gave very good results, both as regards safety from colliery explosions and the production of large coal. Samples of "carbonite" gave better results than before, and the cartridges were better made. Water cartridges—the explosives surrounded with water—gave good results as to safety.

"Ammonia dynamite" consists of 40 per cent. of ammonium carbonate, 10 per cent. of nitre, and 50 per cent. of a mixture of nitro-glycerol and kieselguhr, containing sufficient of the latter to make the mass plastic but not too soft. The introduction of ammonium carbonate is less advantageous than the oxalate. A good mixture is 45 per cent. of ammonium oxalate, 15 per cent. of nitre, and 40 per cent. of the kieselguhr dynamite. It seems possible that by some alteration in the composition of ordinary black powder it may be possible to use it in collieries with safety, ammonium oxalate being used in place of carbon.

"Securite" gave bad results as regards safety from explosion. The Rottweil powder works has consequently much altered and greatly improved this explosive.

"Roburite" was used with success in workings which were free from fire-damp. Analysis failed to show the presence of chlorine in the explosive obtained from Witten, although it was supposed that some of this element was present.

Experiments with Wolf's benzene safety lamp gave very good results.

As regards risk from explosion "ammonia dynamite" proved to be very safe; *Kieselguhr dynamite* and *gelatin dynamite* were bad and about equally so; "Roburite" is better than "gelatin dynamite," but not so good as "ammonia dynamite," although it is possible that this explosive may have been recently still more improved.

"Carbonite," the improved "securite," and "soda dynamite" afford great safety. "Gelatin dynamite No. 2" is as good as "No. 1," and Favier's explosive, one sample of which consisted of dinitrobenzene, mononitronaphthalene, ammonium nitrate and nitre, also gave very good results.

—A. W.

The Annual Report (Thirteenth) of Her Majesty's Inspector of Explosives for 1888.

THE 13th annual report on the working of the Act, signed by Colonel Majendie, H.M. Chief Inspector of Explosives, and his colleagues, Colonel Ford and Major Cundill, has just been issued. The total number of factories now under license is 112, with 353 magazines.

The factories and magazines are under the direct supervision of the inspectors, who report that their visits during the year have been sufficiently numerous to enable them "to speak with confidence and the greatest satisfaction of their general condition." In few instances indeed has there been any tendency towards retrogressions, "and there are now several private factories and magazines which we believe may challenge comparison with any similar establishment in other countries, whether public or private."

The number of deaths from accidents in the manufacture and storage is 6, this being the lowest number on record. Of these 6, three occurred in firework factories.

The four years preceding the passing of the Act show an average of 37 deaths, at which period less than half the present number of factories existed. Dr. Dupré, the chemical adviser to the department, reports a notable increase over the ordinary work of the laboratory, due to the increased importation of dynamite and to the introduction and gradual adoption of new explosives.

No less than 20 applications for a license to manufacture or import new explosives were made during the year. Of these, eight were reported on favourably, nine were rejected, and three were still under consideration at the time of the issue of the report.

It appears from Major Cundill's Dictionary of Explosives that out of a total of 350 suggestions for new explosives, 67 are chlorate mixtures. Of these 67, one only has been authorised. In spite of this fact inventors do not seem discouraged, as there were three chlorate mixtures submitted during last year, one under the name of "safety-powder." "This," says Dr Dupré, "so-called safety-powder is a mixture of chlorate of potassium and glycerin." The other mixture, called "Romit," is described as "another attempt to render chlorate of potassium available as a constituent of an explosive for general use, and, like most attempts, has ended in failure." The third, called "Howittite," has the objection of being not only sensitive to combined friction and percussion, but liable to spontaneous decomposition.

One out of three samples of "Carbonite" passed the necessarily severe tests satisfactorily; as also "Flameless Securite," which has the same composition as "Bellite" with the addition of oxalic acid or oxalates, "Fortis" a nitrate mixture, and others of, at present, little interest. "Bonolithe," a picrate mixture, was still under consideration at the time Dr. Dupré issued his report.

Local authorities appear in many instances to carry out their responsibilities in connexion with the Act in a very reprehensible manner. The report states, "We regret to have to say that, taken as a whole, the system is far below the standard which might reasonably be expected. In some places the work appears to be efficiently carried out by local authorities, while in others, as in some of the smaller boroughs and principal market towns, the work is almost, if not altogether, neglected." One effect is to place the law-abiding trader at a great disadvantage. On the other hand it is satisfactory to learn from the report that there are several important districts and towns in which an attentive and intelligent administration of the Act prevails. The high standard of purity for some time past maintained by "chemical explosives" has led to a relaxation of certain restrictions with regard to the storage of mixed explosives.

The report refers to the appointment by the War Office of a committee of chemists for the purpose of specially

investigating and dealing with chemical questions relating to explosives for use in naval and military services, and Dr. Dupré has been selected as one of the members of the new committee.

An amendment of the law in relation to petroleum has been promised for some time, and much of Colonel Majendie's time has been taken up with the preparation of the Bill.

The steadily progressive increase in the number of factories and magazines, accompanied by an actual decrease in the number of fatal accidents, is remarkable.—C. N. H.

PATENTS.

Safety-Fuse and Igniting Apparatus for setting Fire to Explosive Charges without Danger from the Presence of Fire-damp. H. Müller, Clermont, Belgium. Eng. Pat. 5061, April 5, 1888. 8d.

THE object of this invention is to produce a fuse which will not ignite fire-damp on combustion. This is effected by an envelope of wire, gauze, or similar material fixed on to the fuse in a special way. It is necessary to consult the drawings accompanying this specification in order to clearly understand it.—C. N. H.

Improvements in Fuses. C. A. McEvoy, Southwark. Eng. Pat. 5624, April 16, 1888. 8d.

THE object of this invention is to form a fuse that will be ignited by immersion in water. This is effected by means of sodium or potassium, or a mixture of both, suitably attached to the fuse.

Drawings accompany this specification.—C. N. H.

Improvements in Explosive Compounds. A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 6560. May 2, 1888. 6d.

THIS invention relates to the treatment of nitrated starch and nitrated dextrin for the production of explosive compounds to be used in place of gunpowder.

For this object nitrated starch or nitrated dextrin is incorporated with nitro-cellulose, and both dissolved in a suitable solvent such as acetone, &c. By means of such solvents, which are afterwards distilled off and recovered, a very perfect incorporation can be brought about.

Other explosive substances or oxidising agents, such as picroates, chlorates, nitrates, &c., may be incorporated with the aforesaid materials, the quantity of the solvent being so far increased as to allow of a complete and uniform distribution of the substance to be incorporated.—C. N. H.

XXIII.—ANALYTICAL CHEMISTRY.

Improvements in the Employment of Bunsen's Photometer. B. Nebel. Rep. d. Phys. 24, 724.

As light entering the eye laterally renders it less sensitive to slight differences of shade, the author has introduced a modification of Bunsen's photometer with a view to obviate this, for a description of which we must refer to the original article. For producing the grease spot, a perfectly-rounded brass disk, of 20 mm. diameter, and provided with a handle, is warmed, dipped into molten spermaceti, and after removing excess of the latter, the disk is placed on paper of .061 mm. thickness, which is stretched evenly on a flat board. The corners of the paper are best attached with little brass frames and some Canada-balsam. Since the visual power of the eyes usually differs, it is best to use only one eye for these determinations.—A. R.

Detection of Nitrates in Soils. Frank. Landw. Jahrb. 17, 723—724.

IN reply to Krenslor's suggestion that the blue colouration of diphenylamine produced by sand was due to the presence of manganic and ferric oxides (this Journal, 1889, 306), the author points out that his observations do not support this view, inasmuch as the iron-stained spots on the sand grains did not give the reaction, nor does impregnating the sand with ferric oxide impart to it the power of turning diphenylamine blue; moreover, by prolonged ignition of sand giving the reaction, it is possible to destroy its power to do so. Nevertheless, further investigation of the reaction in question has shown that it is probably neither due to nitrates nor any other plant nutrient.—D. A. L.

Detection of Nitrites in Water. F. Musset. Pharm. C. H. 1889, 195.

IN examining a drinking water for nitrites by means of zinc iodide, starch solution, and acetic acid, the author noticed that the liquid gradually darkened in colour, and after the lapse of 24 hours was quite a dark blue. The reaction is as a rule at an end after the lapse of a couple of hours. This water contained a large number of bacteria; it contained no iron; the sediment from the blue solution contained, amongst colourless forms, deep blue cylindrical forms of bacteria. The author concludes, therefore, that the bacteria are the cause of the colouration, and that these consequently have the property of liberating iodine from an acidified solution of zinc iodide and starch. After distillation no blue was obtained, so that only the distillate should be used.—T. L. B.

Characteristic Reaction of Copper-Salts. Denigès. Compt. Rend. 108, 568.

THIS reaction is based on the transformation of copper salts generally into cupric bromide by the action of potassium bromide. The cupric bromide, after drying over sulphuric acid, dissolves in an excess of the bromide with a red-violet colouration.—A. R.

Investigations on the Methods for the Valuation of Argol. P. Boessneck. Chem. Zeit. 13, 356—357.

THE author recommends the Goldenberg-Geromont method as the most reliable for the determination of the total tartaric acid in argol, and traces the high results (2—4 per cent. too high) obtained by both Lorcé's and Fresenius' modifications of Goldenberg's original method, either to alkali being retained by humus substances in the crude sample, or to the fact that the latter prevent the complete removal of the excess of acetic acid added in the precipitation of the acid potassium tartrate. (See this Journal 1888, 136, 239 and 349.) The analysis is carried out as follows:—Treat 10 grms. of the finely-powdered sample with 15 cc. of hydrochloric acid of sp. gr. 1.1, stir well, allow to stand, and make up to 203 cc. (3 cc. correspond to the volume occupied by the insoluble portion); filter the solution through a dry filter-paper, and heat 100 cc. of the filtrate in a flask. Then add potash till strongly alkaline, boil the solution, filter off the precipitate, and wash till free from alkali. The filtrate is treated with hydrochloric acid till only just alkaline, concentrated to 20 cc., allowed to cool, and warmed with 5—6 cc. of glacial acetic acid for 10 minutes on the water-bath. 100 cc. of absolute alcohol are next added and the whole allowed to stand for 2 hours before filtering; the precipitate is washed with alcohol until 20 cc. of the filtrate, diluted with an equal volume of water, are reddened by the addition of a drop of semi-normal alkali, after adding phenolphthaleïn. The titration is effected in the usual manner until the solution is almost neutral (this point being judged by means of litmus paper), and the final point tested in the boiling solution, using paper soaked in an ammoniacal solution of the artificial colour "azo-litminum," and then allowed to dry in the air. The paper thus prepared is of a pale pink colour, and turns blue on the addition of alkali. The determination of the quantity of acid potassium tartrate in argol in the

presence of calcium sulphate presents difficulties which the author suggests might be overcome by adding an excess of antimony oxide (Sb_2O_3), and then determining the amount of the latter, combined with the cream of tartar, after boiling and filtering, either gravimetrically or volumetrically. One molecule of cream of tartar takes up half a molecule of Sb_2O_3 . The results, however, appear dependent upon the degree of concentration of the solution, and also upon the quantity of the excess of antimony oxide added; this makes it necessary to work the method under constant conditions.

—C. A. K.

Volumetric Determination of Chromium in Chrome-iron Ore. C. Reinhardt. Chem. Zeit. 13, 430.*

THE finely powdered chrome ore (0.5 gm.) is fused for two hours with potassium bisulphate. The ore is completely decomposed by this means, which is not the case if soda be employed. The method is useful when a complete analysis of the chrome ore is required, since on treating the fused mass with water, insoluble basic chromium sulphate separates. If the chromium only is to be determined, J. B. Britton's method (Fresenius Quant. Analyse, p. 354) is more suitable; the chrome ore being fused with potassium chlorate and soda-lime yields the chromium as chromate. The solution of the melt after separating silicic acid is mixed with manganese sulphate, then with an excess of an acidified ferrous sulphate solution of known strength, and the latter titrated back with permanganate. The yellow colour produced by the latter is avoided by addition of phosphoric acid. No more permanganate should be added after the solution is coloured violet. Presence of manganese in the chrome-iron ore renders this method faulty, since when fused with chlorate, manganates or permanganates are formed.—A. R.

On the Determinations of Nickel as its Sulphide. A. Leerenier. Chem. Zeit. 13, 431 and 449.

COMPLETE precipitation of nickel sulphide with ammonium sulphide is only possible if the latter contain no polysulphides. As freshly-prepared ammonium sulphide rapidly turns yellow, it is difficult to have the reagent as pure as seems desirable for nickel determinations. By adding a certain quantity of sodium sulphite, however, the change into polysulphides is obviated. The author mixes one volume of ammonium sulphide with two volumes of a 10 per cent. sodium sulphite solution, and this solution is rendered colourless by heating on the water-bath. In a table which is appended, the author gives the results of experiments on this subject, which may be summed up as follows:—Precipitation of nickel by decolourised ammonium sulphide is only complete when the solution of the nickel salt does not contain less than 0.1 gm. of Ni for every 200 cc. of water. In very dilute solutions complete precipitation may be effected by adding a relatively small quantity of ammonium chloride, carbonate, or acetate. This is to prevent nickel sulphide remaining in solution in the colloid form. Presence of ammonia may entirely or partially prevent precipitation of nickel as sulphide; thus at a certain concentration colourless solutions may be obtained containing both a nickel salt and ammonium sulphide. It is therefore advisable to remove excess of ammonia by boiling and saturating the last traces with carbonic acid before adding ammonium sulphide. Regarding the cause of nickel sulphide being incompletely precipitated by ammonium sulphide containing polysulphides, the author believes this to be due to the formation of soluble ammonium sulpho-nickelate, and adduces the following facts in favour of this view. (1.) Ammonium sulphide which has been decolourised with mercury precipitates all nickel from solutions of any degree of dilution. (2.) Pure ammonium sulphhydrate (i.e., free from ammonia) which has been saturated with sulphur completely dissolves nickel sulphide. Moreover, a solution of the latter in ammonium polysulphides is not precipitated by boiling with sodium sulphite. Probably in this case the higher sulphide of nickel which is first formed, having been converted into an ammonium sulpho-nickelate decomposition by sodium sulphite, can no longer take place.—A. R.

On the Testing of Spent Substances from Gas Purification. C. Moldenhauer and W. Leybold. Jour. f. Gasbeleucht. 32, 155.

THE authors give a new method of determining the Prussian blue in the spent material. Formerly Knublauch's method was the most used, but the end of the titration was often uncertain. By the authors' process 50 grms. of the spent substance are placed in a flask with 100 cc. of a solution of 10 per cent. caustic soda and 2 per cent. sodium carbonate, heat is applied to hasten the decomposition, and the whole is then diluted to 1,030 cc. 100 cc. of the filtrate are evaporated down in a platinum or porcelain basin and treated with 25 cc. of dilute sulphuric acid (10 per cent.). After further evaporation the excess of acid is driven off and the organic matter destroyed by ignition. The yellow residue consists of ferric sulphate and sodium sulphate, which is dissolved in dilute sulphuric acid. The iron is reduced to the ferrous state by means of zinc and titrated with permanganate solution. From the iron thus found the amount of Prussian blue is calculated. A blank experiment should be made to ascertain the slight correction for impurities in the zinc. Concordant results were obtained by several chemists working independently.—G. H. B.

Colour Reactions of Certain Ethereal Oils. A. Ihl. Chem. Zeit. 13, 264.

Peppermint-oil mixed with alcohol and a little powdered sugar assumes a bluish-green colour when heated with dilute hydrochloric or sulphuric acid. Menthol which is contained in this oil does not give the reaction. Phloroglucinol is a very delicate reagent for these ethereal oils which contain eugenol. Thus, clove-oil which consists of eugenol and a sesqui-terpene $C_{15}H_{24}$ gives a bright red colour when treated with alcoholic phloroglucinol and concentrated hydrochloric acid. Resorcinol employed in the same manner causes a red-violet colouration and pyrogallol a violet one. Cinnamon-oil (cassia-oil) treated as above with phloroglucinol gives a deep red colour, and with resorcinol a cinnabar red. Pimento-oil is coloured pink by phloroglucinol, and dirty violet by resorcinol in alcoholic solutions and with addition of hydrochloric acid. The three last named ethereal oils, when mixed with alcoholic aniline sulphate and dilute hydrochloric acid, assume a yellow colour, especially on boiling. It is probable that this reaction is due to eugenol contained in these oils.—A. R.

Some Reactions of "Vanado-Sulphuric Acid" on Glucosides and Alkaloids. F. Kundrát. Chem. Zeit. 13, 265.

THE reagent was prepared by dissolving 0.1 gm. of ammonium vanadate in 10 cc. of conc. sulphuric acid.

Substance.	Gives with Vanado-Sulphuric Acid a Solution coloured
Aconitine	Light coffee-brown.
Atropine.....	Red, then yellowish-red, finally yellow.
Apomorphine.....	Dark violet-blue, rapidly changing to dirty-green, finally reddish to light brown.
Brucine.....	Intense blood-red, gradually changing to original colour of solution.
Cinchonine	Faint orange, gradually green.
Cocaine.....	Orange (foams on dissolving).
Codeme.....	Greenish-brown, gradually darker, finally brown.
Colchicine	Green, then brownish-green, finally coffee-brown.
Conine.....	Intense green, gradually becoming brown.
Digitaline.....	Intense brown with red shade, then quite brown.
Quinidine	Faint bluish-green.
Quinine.....	Slightly orange, then bluish-green, finally greenish-brown.

Substance.	Gives with Vanado-Sulphuric Acid a Solution coloured
Caffeine.....	No reaction.
Morphia.....	Brown.
Narceine.....	Brown, changing to dirty bluish-violet, then gradually reddish-brown.
Narcotine.....	Blood-red or purple.
Nicotine.....	Slightly darker, soon assumes same colour as original solution.
Papaverine.....	Violet with brown shade, gradually changing to bluish-green and then orange-green.
Picrotoxin.....	Hardly changed.
Pilocarpine.....	Light orange.
Piperine.....	Intense reddish-brown to black.
Physostigmine...	Greenish-yellow, then purple, finally yellowish-brown.
Salicylic acid.....	Brownish-green, becoming darker.
Antifebrine.....	Changes quickly from purple to brown.
Antipyrine.....	Intense greenish-blue, gradually bluer.
Kairine.....	Dirty pink, quickly changing to dirty light brown, and finally dirty brownish-green.
Santonine.....	No reaction.
Solanine.....	Coffee brown; after a short time the edge of the drop is coloured purple, towards the middle yellow, and in the middle dirty green. After two hours the drop changes to a gelatinous mass of an intense violet colour.
Strychnine.....	Bluish-violet, gradually changing to reddish-violet, purple, and brilliant red.
Veratrine.....	Brownish-red, gradually becoming a dark reddish-violet.

—A. R.

Examination of Creosote. W. Brandes. Arch. Pharm. 1889, 411.

THE German Pharmacopœia requires the sp. gr. 1.03 to 1.08 for creosote from beechwood tar. This is a mixture of guaiacol and cresol, the former of which has the sp. gr. 1.117, and the latter 1.088 at 15° C., from which it is evident that the specific gravity of good creosote must be higher than that given in the Pharmacopœia. A creosote which was free from phenol and cresol fulfilled the above requirements without containing any guaiacol cresol. It consisted chiefly of the homologues of cresol, viz.:—xylol and phlorol. The Pharmacopœia gives no reactions for determining guaiacol and cresol, but the property of their forming potassium salts, which are with difficulty soluble in alcohol, may be made use of for this purpose. The author states:—10 cc. of an alcoholic potash solution (1 part of KHO dissolved in 4 parts of 96 per cent. alcohol) shaken up with 1 part of creosote gives after some time a solid crystalline mass.—A. W.

Reactions for distinguishing Carbolic Acid and Resorcinol from Salicylic Acid. L. van Itallie. Apoth. Zeit. 4, 99.

By adding two drops of ferric chloride solution to 100 cc. of a 2 per cent. solution of phenol, resorcinol or a saturated solution of salicylic acid, a bluish-violet colour is produced. On now adding one drop of lactic acid the colour immediately changes to yellowish-green in the case of phenol or resorcinol, whilst with salicylic acid the original colour is maintained even if 10 drops of lactic acid be added.—A. R.

Quantitative Determination of Aniline and Monomethylaniline. F. Reverdin and C. de la Harpe. Chem. Zeit. 13, 387—388 and 407—408.

Two methods are at present in use for the determination of monomethylaniline. One depends on the rise of temperature, which is produced by adding acetic anhydride to the mixture under examination; the other (proposed by Nölting and Boas Boasson, Ber. 10, 795) consists in converting the monomethylaniline into methylphenylnitrosamine, $C_6H_5.N(NO).CH_3$. The former method can only be used for the examination of mixtures of mono- and dimethylaniline free from aniline; the latter, however, may be used in presence of aniline. At the same time the acetic anhydride method can only be used where small quantities of monomethylaniline are present; thus a mixture containing 2.82 per cent. showed a rise of 0.815° per 1 per cent., which coefficient used in the case of a mixture containing 9.36 per cent. of monomethylaniline gave a sufficiently satisfactory result, viz., 9.57 per cent.; but on raising the percentage to 29.55, an altogether unsatisfactory result was obtained, 37.42 per cent.

The other method is carried out in the following manner:—10 grms. of the mixture under examination are dissolved in 20 cc. of hydrochloric acid and 125 cc. of water, and a solution of 12.5 grms. of sodium nitrite is then gradually run in, the whole being well cooled. The methylphenylnitrosamine formed is then extracted with ether. Its weight multiplied by 0.786 gives the amount of monomethylaniline in the mixture.

The present authors, in order to obtain the nitrosamine pure, then distilled it with steam. They obtained it by this means as a light yellow oil, as it is usually described, but at + 2° C. it crystallised, forming masses of needles, the temperature at the same time rising to + 14° C. It melts at 12°—15°. After the distillation with steam there remained a yellow liquid, from which, on cooling, a quantity of yellow needles separated. These melted at 102°—103° C. and consisted in all probability of nitrophenylmethylnitrosamine, $C_6H_4(NO_2).N(NO).CH_3$, so that in the reaction nitroso-nitrosamine must have been formed by the excess of sodium nitrite, and then oxidised to nitronitrosamine. As this substance together with *p*-nitrodimethylaniline, $C_6H_4(NO_2).N(CH_3)_2$, was repeatedly obtained, the action of an excess of sodium nitrite was tried on pure monomethylaniline. No phenylmethylnitrosamine was obtained in this case, but a large quantity of nitronitrosamine. The formation of nitrophenylmethylnitrosamine, whose molecular weight is 181, while that of phenylmethylnitrosamine is only 136, is sufficient reason for considering the method inaccurate.

The authors attempted a separation by distilling salts of the bases with steam, but without success.

They obtained good results, however, by the following method:—

The aniline is determined by converting into diazobenzene and titrating with a solution of "R salt" (sodium salt of a β -naphtholdisulphonic acid). The monomethylaniline is determined by adding to the mixture a known quantity of acetic anhydride and titrating the excess of the latter with caustic soda solution.

When aniline or dimethylaniline are heated with acetic anhydride or glacial acetic acid secondary reactions occur, which would make this method of analysis inaccurate, so that whilst the reaction is in progress heat must not be applied. By boiling aniline for two hours with a considerable excess of acetic anhydride a much larger quantity of the latter is used up than is necessary for the formation of monoacetanilide; in all probability diacetanilide is formed in this case. Dimethylaniline heated for some time with a large excess of glacial acetic acid gives from 10—15 per cent. of tetramethyldiamidodiphenylmethane.

At ordinary temperatures excess of acetic anhydride quickly converts aniline and monomethylaniline quantitatively into monoacetanilide and methylacetanilide, whilst dimethylaniline remains for some considerable time unacted

upon, and even then the action is very slight. The analysis is carried out as follows:—

Determination of the Aniline.—Prepare a titrated solution of R salt, containing in 1 litre the equivalent of about 10 grms. of naphthol.

Dissolve 7–8 grms. of the mixture under examination in 28–30 cc. of hydrochloric acid and make up with water to 100 cc. Take 10 cc. of this solution, dilute with water and ice, and diazotise, using so much nitrite as would be used if aniline alone were present. Pour the product slowly into a measured quantity of the R salt solution, to which has been added excess of sodium carbonate. Salt out, filter, and ascertain excess of either by means of diazobenzene solution and R salt. A mixture containing 10.76 per cent. of aniline showed 10.24–10.40 per cent.

Determination of the Monomethylaniline.—Into a flask fitted with reflux condenser weigh 1–2 grms. of the mixture, add as quickly as possible a known weight of acetic anhydride, corresponding to about twice the weight of the mixture taken, and allow to stand for about half an hour; then add about 50 cc. of water and heat on a water-bath for three-quarters of an hour in order that the excess of acetic anhydride may be fully transformed. Cool, make up to a known volume, and titrate with caustic soda solution (phenolphthalein may be used as indicator). The amount of monomethylaniline may then be ascertained from the amount of acetic anhydride actually used, after deducting, of course, the amount necessary for the aniline—T. L. B.

Determination of the Free Alkali and Free Fatty Acid in Soap. E. Dieterich. Helffenberger Ann. 1888.

Dissolve one part of soap in 20–50 parts of water, and add so much sodium chloride that a little remains undissolved. Filter, and wash with a little saturated salt solution; dissolve the mass in water, and again salt out and filter as before. Combine the two filtrates and determine the free alkali by means of centinormal H_2SO_4 and phenolphthalein.

Dissolve the soap, salted out above, in 30 cc. of absolute alcohol by warming in a water-bath, add phenolphthalein and titrate with centinormal KOH. Calculate as oleic acid. As the alcohol frequently contains substances which decolourise phenolphthalein, it is necessary to determine separately the amount of centinormal KOH required to redden the phenolphthalein in 30 cc. alcohol, and to subtract this from the former determination.—T. L. B.

Method for Ascertaining the behaviour of Lubricating Oils at Low Temperatures. A. Hoffmeister. Mitth. d. Königl. techn. Versuchs. 1889, 21–27.

THE methods commonly used at the present time leave much to be desired, involving as they do errors objective and subjective. The following is the plan proposed to replace them:—About 4 cc. of the oil to be tested are introduced into a test tube and exposed to a constant predetermined temperature, a few degrees below zero, for one or two hours, at the end of which time it may be assumed to have acquired the greatest degree of consistency attainable at that temperature. Its precise condition can be judged by inclining the tube, probing it with a glass rod (cooled to the same extent) or by other suitable means. The tube containing the semi-congealed oil is then exposed in a similar way to a temperature a few degrees lower, and so on until solidification occurs. The constant, known, low temperatures are obtained by partly freezing solutions of various metallic salts in water, which are of such strengths that they are saturated at their freezing points. Such solutions when partially frozen remain constant in temperature until they have wholly solidified or wholly liquefied. Examples are given in the following table:—

Salt.	Parts per 100 of Water.	Freezing Point.
Potassium sulphate	10	- 1.9° C.
Sodium carbonate (crystallised)	20	- 2.0 ..
Potassium nitrate	13	- 2.85 ..
" chloride	30	- 10.9 ..
Ammonium	25	- 15.4 ..
" nitrate	45	- 16.75 ..
Sodium	50	- 17.75 ..
" chloride	33	- 21.30 ..
Barium	35.8	- 8.70 ..

If any particular degree not given in this table be adopted, help may be had in obtaining the conditions necessary for its attainment, by recourse to the device of mixing some other salt with one or other of those there recorded. For example, a solution of potassium nitrate freezing at -2.85° C. has its freezing point lowered 0.6° C. by the addition of 1 gm. per 100 of sodium chloride. This plan is not without objection, as the saline solution being no longer saturated in respect of one of its constituents, viz., the sodium chloride, does not deposit that body on being frozen, and therefore alters in degree of concentration, so that, while it liquefies, small variations in the temperature occur. However, by limiting the proportion of sodium chloride, and avoiding freezing too much of the saline liquid, this error becomes negligibly small.

Some mixtures giving temperatures approximating to those indicated by certain convenient round numbers are given in the following table:—

Freezing Point.	Substances used.	Parts per 100 of Water.
0° C.	Water
-2.85° approximating to 3° C.	Potassium nitrate ..	13
5° C.	Potassium nitrate ..	13
	Sodium chloride ...	3.3
- 8.7° approximating to 9° C.	Barium chloride ...	35.8
-15.4° .. 15° C.	Ammonium chloride ..	25

Solutions once made up can be kept and used repeatedly.
—B. B.

The Determination of the Solidifying Points of the Fatty Acids from Tallow, of Beef Tallow, and of Lard. Finkener. Mitth. Königl. techn. Versuchs. 1889, 27–41.

THE determination of the solidifying points of such liquids as water is easy, because if by sudden cooling the solidifying point be passed, the temperature of the mass rises again to the normal temperature when once solidification occurs. With fats and fatty acids, however, this rise is but gradual, and may not be discerned at all if the cooling agency be a powerful one, as the heat given out may be absorbed by it as fast as it is produced. Accuracy can be attained by using considerable quantities of the fat or fatty acid undergoing observation, and taking care that the cooling is very slow.

An elaborate series of experiments was made both in test tubes and flasks of various sizes, covered with wadding, buried in iron filings, or exposed freely to the air of the room (which was kept at different known temperatures), in order to determine the influence of such circumstances on the solidifying points of the substances mentioned in the heading; the results are recorded in voluminous tables quite unsuited for abstraction.

The conclusions arrived at were:—

(1.) An envelope of wadding raised the solidifying point of the fatty acids from tallow by about 0.3° C., when a

tube 18 mm. wide was used, and about 0.1°C . when one 45 mm. in diameter was employed.

(2.) The difference between the solidifying points determined in an 18 mm. tube and in a 45 mm. tube was about 0.7°C ., the wider tube giving the higher reading. The temperature remained constant at the solidifying point for 2 and 10 minutes respectively.

(3.) The substitution of a bulb of the same, or greater, diameter than the 45 mm. cylinder was without influence on the results.

The author recommends the use of a globular flask 45 mm. in diameter, carrying a thermometer of which the bulb is about the centre of the flask, surrounded with wadding, and allowed to cool in a room at the ordinary temperature. With this apparatus the thermometer remains stationary for 10 minutes at the solidifying point.

It was further found that considerable variations in the mode of saponification of the tallow used—such as differences in the quantities of potash, alcohol and water employed, time of heating, mode of freeing the fatty acids, &c.—did not affect the melting point of the fatty acids obtained. The method of Dalican, used in London and Paris for commercial purposes, is not satisfactory. It consists in melting the fatty acids in a test tube 18 mm. wide, placing it in another somewhat wider, leaving the thermometer at rest until the fatty acids begin to solidify at the edges, when it is moved round first to the right, then to the left, finally stood in the middle and its highest reading taken. It is difficult to decide when to begin this stirring, and solidification is inconveniently rapid.

Next, with regard to tallow it was found that the solidifying point rose with the quantity taken whether an envelope of wadding was used or not.

The following table gives some idea of the variations observed:—

Vessel used.	Solidifying Point.	
	Without Padding.	With Padding.
Test tube, 18 mm. wide ..	37.82°C .	41.23°C .
Flask, 50 mm. wide	41.15°C .	45.35°C .
" 80 " "	45.81°C .	46.50°C .
" 135 " "	47.90°C .	47.38°C .

In the case of lard the phenomenon was more complex. The solidifying point rose with the quantity taken, provided that no envelope was used. When it was used, and the quantity of lard was fairly large, the solidifying point actually fell below the value given by direct cooling in air, and a noticeable separation into a solid and a liquid portion took place. The author considers this separation to have an important bearing on the matter, since it renders possible the influence of one or both of the following two causes of error. *First*, the portion that solidifies first is free to sink to the bottom of the vessel, and being thus removed from the sphere of action, fails to promote the solidification of the remainder (as it otherwise would), and thereby to bring about the resulting rise of temperature. By artificial cooling of the lowest point of the flask (as by an ether spray) so as to solidify a portion of the mass, mixing this solidified portion with the remainder of the lard, and by finally letting the whole solidify spontaneously, it may be shown that the solidifying point thus obtained is about 0.4°C . higher than that got by allowing the flask to cool without any such treatment. *Secondly*, the central portion surrounding the thermometer bulb may lose heat, on account of the continued liquidity of the fat and resulting convection currents, which would not exist in a semi-solid medium. From these considerations it does not appear likely that any simple plan on the same lines as suffice for tallow can be formulated for the determination of the solidifying point of lard.—B. B.

On the Determination of Glycerol. T. Morawski.
Chem. Zeit. 13, 431.

50—60 grms. of lead oxide are weighed out into a large porcelain crucible, followed by about 2 grms. of the glycerin to be examined, enough alcohol having been added to facilitate the thorough mixture of glycerin and oxide. The contents of the crucible are first heated to 100° , then to 120° — 130° , until the weight becomes constant. The results differ by about 0.5 per cent. Tables are appended giving the figures obtained with different samples of glycerin examined by the author's method, comparing these numbers with those deduced from the sp. gr. tables of Leuz and others, and furthermore with the numbers found by combustion of the glycerin. Fairly close agreement with the latter proves the author's method to be satisfactory, and he claims that weighing as the lead compound is at present the most reliable and rapid method for the determination of actual glycerol in the commercial product.—A. R.

On the Estimation of Glycerol in Brandy Lyes.
H. G. von Törring. Landw. Versuchs. 36, 23.

ACCORDING to the author the various methods for the estimation of glycerol are subject to important sources of error, which are avoided in a new method depending on the following facts: (a.) A solution of glycerol may be evaporated, without losing a trace of glycerol, until the residue contains 50 per cent. of water. By mixing the residue with burnt gypsum most of the water is absorbed, and a mass obtained suitable for the extraction of the glycerol by a solvent. (b.) The glycerol can be completely separated from the non-volatile matters by distillation *in vacuo* at a temperature of 180° . (c.) The aqueous glycerol obtained by distillation is suitable for precipitation of the glycerol as benzoate. The method of procedure is to evaporate 30 cc. of the filtrate from the lyes on the water-bath to 5 cc. Then 15 grms. of burnt gypsum are mixed with the residue, and when the mass begins to set it is well powdered and exhausted for 6 hours with alcohol in an extraction apparatus. The alcoholic solution is treated with 10—20 cc. of water, and heated until all the alcohol is driven off, when the residue is distilled. The distillation apparatus consists of a retort resting in an air-bath, and a Liebig's condenser. The receiving flask has a neck connected with an air pump. The distillation is at first carried on at 150° — 170° without working the air pump, until all the water has passed over into the receiver. Then the pump is set to work, and the temperature raised to 190° — 210° . When all the glycerol has come over, about 3 to 4 cc. of water are added to the contents of the retort, and distilled at 150° — 170° , under ordinary pressure, in order to wash all the glycerol into the receiver. The yellowish distillate, amounting to 10 or 15 cc., is mixed in the receiver with 5 cc. of benzoyl chloride and 35 cc. of a 10 per cent. solution of caustic soda, with frequent cooling and shaking to consolidate the precipitated glycerol benzoate, which is finally collected on a weighed filter, washed with water, and dried for 2 to 3 hours at 100° .—G. H. B.

Examination of Malt Extract. E. Dieterich. Helfenberger Ann. 1888.

SOLID matter is determined in 2 grms.; the dried extract serves for determination of the ash, and this latter for determination of the phosphoric acid. Free acid is determined by titrating a solution of 10 grms. of extract in about 50 cc. of water with seminormal ammonia, using delicate litmus paper. In order to determine the albuminous substances, 2 grms. of extract are well dried, and the nitrogen determined by Kjeldahl's method and multiplied by 6.25.

Maltose.—A solution of 1 grm. of malt extract is made up to 100 cc. and the maltose determined gravimetrically and volumetrically by Fehling's solution. The result is only approximate owing to the presence of other substances, e.g., dextrin, which reduce Fehling's solution. The error due to the small quantity of dextrin in good malt extract is, however, not of much moment.

Dextrin.—To a solution of 5 grms. of extract in 25 cc. of water are added slowly 100 cc. of absolute alcohol, the whole being kept well stirred. This is allowed to stand for 12 hours and is then filtered; the residue is washed with alcohol, dissolved in 60 cc. of water, boiled, filtered, cooled, and made up to 100 cc.; 50 cc. of this are titrated with Fehling's solution. The remaining 50 cc. are heated for three hours on a water-bath with 0.5 cc. of hydrochloric acid, then neutralised carefully with caustic soda and titrated with Fehling's solution. The difference of the two titrations is calculated as dextrin.

Diastase.—Into a number of test-tubes are introduced 10 cc. of a 1 per cent. starch solution; to the first tube is then added 0.2 cc. of a 10 per cent. malt extract solution, to the second 0.3 cc. and so on. The tubes are then heated for three hours to 60° in a water-bath and are then tested for starch by adding a drop from each to an iodine solution. The percentage of diastase may be ascertained from the fact that one part of diastase decomposes 2,000 parts of starch.—T. L. B.

On Commercial Oleic Acid. Its Adulteration with Linseed Oil and Detection of the Lutter. Grauvall and Valser. J. Pharm. Chim. 1889, 232.

TEXTILE fabrics made from wool, which previous to spinning has been greased with olein, often show yellow streaks which cannot be removed by sulphurous acid. Moreover the thread is rough and sticky, there is a large quantity of waste, and the removal of the grease is attended with difficulties. The cause of this is sometimes the presence of mere traces of linseed oil in the olein. For the last few years fresh animal fat has generally been deprived of its more fluid constituents (margarin) at a gentle heat, and to the remaining mass, which consists chiefly of stearin and yields a hard cake of fatty acids on saponifying not readily pressed or purified, linseed oil is added. Now the latter contains solid fatty acids, which increases the yield of products for candle manufacture, but at the same time the oleic acid pressed out of this mixture contains linoleic acid which is easily oxidised and dried. Such olein is of a lighter colour than commercial oleic acid. Its sp. gr. is .912—.919, that of oleic acid being .905. By heating the impure product to 50°, it becomes more viscid on cooling, and, by repeatedly warming and cooling, the mass gradually assumes the consistency of butter. When 50 grms. of oleic acid are shaken with 450 cc. of 85 per cent. alcohol complete solution is effected; in presence of linoleic acid a lustrous precipitate is produced, which may be readily distinguished from a possible precipitate due to mineral oils, resin, fatty oils, or paraffin. After washing with alcohol and drying, the precipitate in the former case melts at about 47°. It dissolves readily in boiling spirit, separating again on cooling. The soap obtained by saponification dissolves in warm water, the solution becoming gelatinous on cooling. When 48 grms. of oleic acid containing linoleic acid are treated for one day with 4 grms. of Pontet's reagent, the acid remains quite fluid, the more fluid the greater the quantity of linoleic acid present. Pure oleic acid under similar conditions solidifies completely. A thin layer of oleic acid spread over a well polished lead sheet is almost unchanged after one day. In presence of linoleic acid it has a resinous appearance. On mixing a little of such impure oleic acid with an equal volume of caustic soda, an intense yellow colour is produced, whilst pure oleic acid is only coloured grey.—A. R.

Notes on Testing Commercial Olein. H. Hager. Pharm. C. H. N. F. 10, 130.

Good commercial olein is yellowish to brownish yellow, liquid at 20°, forming a buttery sediment at 15°, and solidifying to a buttery mass at 5°. It has a specific gravity of .912—.916 at 15°—20°, and is miscible in all proportions with alcohol of 85 per cent., and with petroleum spirit. It gives a firm gelatinous mass when shaken with

twice its volume of alcoholic ammonia (10 per cent.), but if mineral or resin oil be present in larger quantities the gelatinous mass does not form, and the neutral oil remains undissolved.—G. H. B.

Difference between the Extract from Tobacco Ribs and Tobacco Leaves. E. Geissler. Gartenflora, 37, 650—651.

The author has analysed two tobacco extracts with the following results per cent. : —

	Tobacco Extract 40° B.	
	Ribs.	Leaves.
Liquid	32.8	36.2
Mineral matter	22.1	15.5
(Containing potassium carbonate	7.73	9.50)
Organic matter	48.4	50.86
(Nicotine	1.86	8.1)

* Defective type in original.

The differences in mineral matter and nicotine are very great, therefore when purchasing tobacco extracts it is advisable to know if it is from ribs or leaves.—D. A. L.

PATENTS.

Improvements in Apparatus applicable for use as Retort Stands, Filtering Stands, or the like for Chemical, Pharmaceutical, and Household or other Purposes. F. D. Delf, Dewsbury. Eng. Pat. 6874, May 8, 1888. 8d.

The stand is formed of a stout iron ring, attached to three adjustable telescopic legs. The aperture of this ring can be reduced in size by a series of other rings differing in internal diameter. One side of this ring carries a short vertical tube having a sliding rod passing through it, capable of adjustment, and of sufficient length to reach the floor, and to project a considerable height above the ring. This rod carries several stout retort-rings, one of which can have its aperture reduced by a moveable rest projecting inward, and supported on a screwed pin or bar. By these arrangements, apparatus of various kinds and sizes can be supported for chemical and other operations. When not in use the whole stand can be quickly taken to pieces, so as to be packed into a small compass.—E. S.

Improvements in Apparatus for Testing and Detecting the Presence of Gases or Gaseous Mixtures. T. Shaw, Philadelphia, U.S.A. Eng. Pat. 18,105, Dec. 11, 1888. 11d.

This apparatus is designed to indicate the composition of gaseous mixtures (especially mine gases) by determining the proportion of atmospheric air or standard ignitable gas that must be added to bring the mixture to the explosive point. The apparatus consists essentially of two pumps, which drive the gases in any required proportions through a mixing arrangement to the gas tester. The pistons of both pumps are worked by one and the same beam, but by altering the position of one of them, the relation between the quantities of air and gas pumped may be altered at will. The mixture is exploded in the gas tester described in Eng. Pat. 3531 of 1887 (this Journal, 1887, 751). The proportion of carbonic acid is indicated by the effect produced by passing a known volume of the gas through a given quantity of lime water.—A. R. D.

New Books.

A TREATISE ON CHEMISTRY. By Sir H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S. Volume III. The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry, Part V. London and New York: Macmillan and Co. 1889.

THIS, the fifth part of the above classic work on Organic Chemistry, contains a description of the Benzene Hydrocarbons and their Derivatives, with eight and more than eight atoms of carbon, and concludes with the Group of the Terpenes and Camphors, including India-rubber and Gutta-percha.

The following are the principal Groups treated of in detail in the text, which covers 485 pages:—The Styrolene, Cumene, Carbostyryl, Phenylpropionic, Cymene, Laurene, and Mellitene Groups; the compounds containing more than 12 atoms of carbons; Group of the Terpenes and Camphors; the Pinene Group; the Camphene, Limonene, Dipentene, Sylvestrene, Terpinolene, Terpinene, and Phellandrene Groups. In the chapter on the Polyterpenes about 14 pages are devoted to the subject of Caoutchouc and Gutta-percha.

The work concludes, as each volume of the English edition does, with an alphabetical index.

EXAMINATION OF WATER FOR SANITARY AND TECHNICAL PURPOSES. By HENRY LEFFMANN, M.D., Ph.D., and HENRY BEAM, M.A. Philadelphia (U.S.A.): P. Blackiston, Son, and Co., 1012, Walnut Street. 1889.

IN introducing their book to the public, the authors draw attention to the omission of certain processes hitherto considered stereotyped for all works dealing with water analysis. Among these is mentioned the use of soap solution for the determination of hardness, and the authors quote Hehner and Allen in support of their determination to be rid of the well-known Clark's process. On the whole it is clear that it has been the endeavour of the authors to set forth the most advanced analytical methods in the determination of the chemical and hygienic purity of water. The book is one of small 8vo. size, contains table of contents, 102 pages of subject-matter, and an alphabetical index. The text is embellished with some eight wood engravings, and inserted in the pages is a set of some five sheets of printed labels to fix on the bottles of solutions required in carrying out the methods described in the work. The matter is sub-divided as follows:—HISTORY OF NATURAL WATERS, ANALYTICAL OPERATIONS, in which considerable attention is given to the most recently developed methods for testing and determining the Nitrates and Nitrites in waters. INTERPRETATION OF RESULTS. The latter few pages of the book contain some valuable tables of data.

THE PRACTICAL OSTRICH FEATHER DYER. By ALEXANDER PAUL. Revised and corrected by Dr. M. FRANK. Published by Mrs. Dr. M. Frank, "Textile Colourist," 506, Arch Street, Philadelphia, U.S.A. 1888.

THIS work principally consists in an interesting collection of specimens of ostrich feathers dyed to a multitude of the various delicate shades, and carefully arranged in book-form, together with full text, giving all the practical details needed for dyeing such materials to sample, as exhibited in the pages. Besides for dyeing, methods and prescriptions are also given for the bleaching of ostrich feathers. The book contains thus 190 pages of matter, including those adorned with specimens. The size is small 8vo., and at the end of the work is a Table of Contents and also an Index to the Recipes.

YEAR-BOOK OF THE SCIENTIFIC AND LEARNED SOCIETIES OF GREAT BRITAIN AND IRELAND, comprising Lists of the Papers read during 1888 before Societies engaged in Fourteen Departments of Research, with the Names of their Authors. Compiled from Official Sources. Sixth Annual Issue. London: Charles Griffin & Company, Exeter Street, Strand. 1889.

EXERCISES IN THE PREPARATION OF ORGANIC COMPOUNDS. By Professor EMIL FISCHER. Translated, with permission of the author, from the second German edition, by ARCHIBALD KLING, F.I.C., Chief Assistant in the Chemical Laboratory of the Glasgow and West of Scotland Technical College, with a Preface by Professor W. DITTMAR, LL.D., F.R.S., &c. Glasgow: W. Hodge & Co. London: Williams and Norgate. 1889.

THIS little book is strongly bound in cloth-covered cardboard, and contains 72 pages of subject-matter, introductory Preface by Professor Dittmar, Author's Preface, Table of Contents, Method of Preparation of some 55 organic substances of leading theoretic interest for the laboratory student of Organic Chemistry, and an Alphabetical Index. The text is embellished with some 19 very well executed wood engravings representing the forms of apparatus recommended. The work is a faithful translation of the little treatise so well known in Germany as Fischer's "*Anleitung zur Darstellung organischer Präparate*."

Trade Report.

(From the Board of Trade Journal and other sources.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

FRANCE.

Modification of Import Duties on Salt.

The *Journal Officiel* for the 20th April last contains the text of a decree of the French President modifying the rates of Customs duty levied on the importation of salt into France, as follows:—

Sea, saline, and rock salt raw or refined, other than white, imported by land or sea: if of European origin, 2 frs. 40 cts. per 100 kilos.; if of non-European origin, imported direct from a non-European country, 2 frs. 40 cts. per 100 kilos.; imported from European entrepôts, 6 frs. per 100 kilos.

Sea, saline, and rock salt, raw or refined, other than white, imported from Senegal and its dependencies, free.

Sea, saline, and rock salt, refined, white, imported by land or sea: if of European origin, 3 frs. 30 cts. per 100 kilos.; if of non-European origin, imported direct from a non-European country, 3 frs. 30 cts. per 100 kilos.; imported from European entrepôts, 6 frs. 90 cts. per 100 kilos.

Sea, saline, and rock salt, refined, white, imported from Senegal and its dependencies, free.

ITALY.

Classification of Articles in Customs Tariff.

Note.—Lire = 20 s. d. Quintal = 220.4 lbs. avoirdupois.

The following decisions have recently been given by the Italian Customs authorities:—

Ichthyol (patent medicine).—Category 62. Duty, 120 lire per quintal.

Oleine perfumed with essence of myrbane.—Category 66A. Duty, 100 lire per quintal.

On the importation of sulfonal, the surtax of 108 frs. per quintal on the actual net weight (by making deduction of the weight of the immediate receptacles) for alcohol used in the manufacture of this article will be levied.

UNITED STATES.

Recent Customs Decisions.

Phenacetin, creosote, sulfonal, and hydroquinon, which preparations are composed of coal tar, wood tar, and other chemical ingredients, are held to be dutiable at the rate of 25 per cent. *ad valorem*, under the provision in Schedule A. (T. I., 92) for chemical compounds not specially enumerated or provided for.

A substance called white brass, in pigs, which is composed principally of tin, zinc, and lead, and is valued at from 105¢. to 120¢. per ton, is held to be dutiable at the rate of 45 per cent. *ad valorem* under the provision in Schedule C. (T. I., 216) for manufactures of tin, zinc, and other metals.

Elatarium, the expressed and inspissated juice of the elaterium fruit, is held not to be free as a crude drug, but dutiable as a medicinal juice under T. I., 93.

Angostura and aromatic bitters, which the appraiser reports to be proprietary preparations, made by private formulas, protected by trade marks, and not used as beverages, and which, as the labels indicate, "cure dyspepsia, diarrhoea, cholera," &c., are held to be dutiable at the rate of 50 per cent. *ad valorem*, under Schedule A. (T. I., 90) for "proprietary preparations."

Withdrawal of Alcohol from Bond for Scientific Purposes, and of Distilled Spirits for the use of the United States, free of Tax.

A circular, dated the 26th March last, has been issued by the Treasury Department of the United States containing full instructions as to the withdrawal of alcohol from bond for scientific purposes, and of distilled spirits for the use of the United States, free of tax.

CUSTOMS TARIFF OF MARTINIQUE.

Import duties in Martinique are collected under three heads:—
(1.) Customs duties on goods other than of French origin; (2.) Consumption duties on goods without distinction of origin; and
(3.) Maritime petrol duties (*octroi de mer*) on goods also of any origin. The only articles of chemical interest occur under the third head:—

Note.—Kilogramme = 2·204 lbs. avoirdupois. Metre = 3·28 feet.
Hectolitre = 22 imperial gallons. Franc = 9*s*.d.

3. *Octroi de mer* Duties on Articles of any Origin.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

THE MARGARINE TRADE IN SWEDEN.

In a despatch to the Foreign Office, dated the 11th May, Sir F. R. Plunkett, H.M. Minister at Stockholm, says:—

"The discussion of the proposed prohibition of margarine took place in both Chambers of the Riksdag this week, and has resulted in the complete triumph of the protectionist party.

"Both Chambers have agreed to request the Government—

"1st. To prohibit the manufacture in Sweden of margarine or oleomargarine.

"2nd. To prohibit the importation into Sweden of margarine or oleomargarine.

"3rd. To establish at the ports an effective Government control of all cream, milk, and butter imported into Sweden so as to ensure these articles not being below a certain standard.

"According to the forms of the Swedish Parliament, proposals for new legislation made by private members assume the shape of an 'humble request to His Majesty to order,' &c., &c.

"It therefore now remains for the Government to decide what action it will take on this proposal of the two Houses in regard to margarine."

THE NITRATE INDUSTRY IN CHILE IN 1888.

In a despatch to the Foreign Office, dated the 19th January, Mr. W. H. Newman says:—

"The feature of the last six months' West Coast business has been the sale to English joint stock companies of a large number of the nitrate-producing establishments. The handsome dividends earned and distributed by the earlier companies have largely contributed to the ease with which such enterprises have been transferred to English capitalists. At present it is impossible to say whether the prices obtained are within or beyond the value of the articles sold. In general there seems to be an impression that the sellers have gone out on the top of the tide. Most of the sales were made at a time when the price of nitrate was unusually high.

The history of the nitrate industry is one of vicissitudes. A period of inflation has always been followed by one of depression. At the same time the business of production has as a whole been a profitable one for those who have been able to hold on in bad times till the return of prosperity. It would be well for investors to recollect that the dividends paid by the earlier companies were earned during a period of prosperity, and also that a new "oficina" ought to pay best in its first years. Then the raw material lies close to the works, later on it has to be carted considerable distances; also that a nitrate field, however good, is at last exhausted. The great problem in this industry is the relation of supply and demand. For the last two or three years the latter has fully overtaken the former. But if all the companies lately formed are expected to return to their shareholders dividends such as have been paid by the earlier ones, it seems questionable whether the supply will not exceed the demand. This happened some few years ago, and a general crisis was only avoided by a strong combination among producers to limit the output. Should this again become necessary it is difficult to say whether the operation would be facilitated or not by the fact that a large proportion of the production is in the hands of English companies. In the event of the formation of a syndicate to control production there is another element of uncertainty which ought to be kept well before nitrate shareholders. The Chilean Government derives a very large portion of its revenue from the export duty on nitrate. It has lately committed itself to heavy expenses for the extension of railway communication throughout the country; also, for the construction of docks, shipping moles, prisons, and railway stations, besides ironclads and warlike stores. It cannot, therefore, allow a falling in the revenue from the nitrate business, and it is to be feared that any curtailment of production causing a loss of revenue would be met by a corresponding increase in duty on exports. This is all the more likely, as it is no secret that there is a considerable amount of jealousy felt and expressed at the fact that the profits on an article which is essentially a Chilean monopoly should go chiefly in the pockets of foreigners.

In a speech by the President of Chile, at the opening of an exhibition at Santiago, on the 25th of November last, his Excellency said:—"Why does the credit and the capital which are brought into play in all kinds of speculations in our great cities hold back and leave the foreigner to establish banks at Iquique, and abandon to strangers the exploiting of the nitrate works of Tarapaca, from which emanates the sap which gives life to the whole world, and to carry which fleets of merchant vessels never cease to arrive and depart? The foreigner explores these riches and takes the profit of its native wealth in order to give to other lands and unknown people the treasures of our soil, our own property, and the riches we require?"

As before stated, the production of nitrate is and always has been, taking over a series of years, a profitable business; but then no "oficina" as formerly worked, cost anything approaching to the prices lately paid by the joint stock companies, and the present excess of capital is likely to induce over-production in order to pay dividends, and this to an extent unknown to former producers, who were mostly limited by the extent of their means and the general consensus of opinion in a way which is not likely to be effective with public companies.

The total quantity of nitrate exported during the year 1888 amounted to 16,700,000 quintals, equal to 750,000 tons, of which 15,000,000 quintals were embarked for Europe and 1,700,000 quintals to the United States.

BOARD OF TRADE RETURNS.

SUMMARY OF IMPORTS.

	Month ended 30th April.	
	1888.	1889.

STATISTICS.

FIFTY YEARS OF FRENCH FOREIGN TRADE.

Some very interesting statistics regarding the foreign trade of France for the decade between 1877 and 1886, as compared with the five decades preceding, have recently been published. These show that the total trade of the country has increased sixfold during the last half century, the period of by far the greatest expansion being that of the reign of Napoleon III., when a liberal commercial policy prevailed. During the last 10 years French exports have been almost stagnant, the increase between the decade ending in 1886 and its predecessor having been only 24 per cent., as compared with 63 per cent. for the decades 1857-66 and 1867-76. Fifty years ago the principal countries sending goods to France, in order of their importance, were:—United States, Italy, Belgium, United Kingdom, Germany, Russia; now they are:—United Kingdom, Belgium, United States, Germany, Italy, Spain. Fifty years ago the countries to which France sent most goods, in the same order, were:—United Kingdom, United States, Germany, Spain, Italy, Belgium; now they are:—United Kingdom, Belgium, Germany, United States, Switzerland, Italy. The average exports of articles of pharmaceutical interest from France, in millions of francs, have been as follows:—

	Chemicals.	Dye-wood Extracts.	Fixed Oils.	Prepared Medicines.	Common Soap.	Perfumery.
1837-45	7.9	1.1	3.2	3.2	2.3	8.0
1877-86	56.6	17.6	23.0	11.7	8.5	8.2
	1837-46.	1847-56.	1857-66.	1867-76.	1877-86.	
Million francs.,	8.0	10.5	14.2	12.7	8.2	

—Chemist and Druggist.

A CENTURY OF AMERICAN TRADE.

The United States Bureau of Statistics has recently published some figures showing the progress of the United States trade between 1789, the first year of the constitutional government of the Republic, and 1888, the year which completes the first century of its existence as an organised State. The imports in 1789 were declared at a value of 23,000,000 dols.; in 1888, at 753,500,000 dols.; and the exports have grown during the same period from 20,000,000 dols. to 723,500,000 dols. A hundred years ago commercial statistics were not, of course, kept with the same care and detail as at present, but the following figures will convey some idea of the growth of some of the exports of the country of interest to the drug trade. They refer to the exports for the entire year 1789, and those of the ten first months of 1888, the complete figures of the latter year not being in our possession at present:—

—	Potash.	Candles.	Spermaceti.	Whale Oil.	Ginseng.
	Dols.	Dols.	Dols.	Dols.	Dols.
1789	661,634	45,113	79,542	124,08	47,924
1888	891,918	1,654,864	322,637	1,528,376	299,569

—	Medicines.	Soap.	Seeds and Roots.	Perfumery.	Lard.
	Dols.	Dols.	Dols.	Dols.	Dols.
1789	1,733	3,967	2,689	73,579	31,175
1888	1,373,723	17,718,127	118,832	9,728,314	876,671

No sufficient statistics of imports were kept a century ago to admit of comparison.—*Chemist and Druggist.*

MISCELLANEOUS TRADE NOTICES.

AMERICA'S OIL SUPPLY.

See Board of Trade Journal for May, pp. 542.

THE PRODUCTION OF SISAL HEMP.

See Board of Trade Journal for May, p. 544.

THE TRADE OF CHILI IN 1888.

See Board of Trade Journal for May, p. 550.

DISTILLATION OF MINERAL OIL FROM PEAT IN BRAZIL.

The *Bulletin de Musée Commercial* for the 20th April last, with respect to the distillation of mineral oils from peat in Brazil, says:—

"Under the heading of 'Brazilian petroleum,' the *Comercio* of Amazonas gives interesting details respecting the distillation of peat, which is carried on by a large firm at Marahu. Up to the present, there have been worked 10 beds of an area of 82 hectares 360 metres square. The value of the beds may be gathered from the fact that solid peat is met with up to a depth of 150 feet, without any signs announcing the end of the bed being found.

"The firm employs at the present time 300 workmen, and 33 boilers, with washers, stills, refrigerators, steam saw mill, foundry, forges, &c. The workshop, fitted with the latest improvements, can produce 3,000 cases per month. The paraffin will be used for candles; plant is being set down which will produce 80 tons monthly. Besides, from the raw material itself, a lubricating oil for all kinds of machinery is extracted.

"The concessionaires have constructed a large quay, 14 feet deep, where two ships of 900 tons have already been berthed to be unloaded."

A NEW TEXTILE.

M. Vicente Solis Leon says, in the *Revista de Merida*, that a new textile plant has just lately been attracting some attention in Yucatan. The natives recognise it under the name of *atuc*. The *atuc* shoots on the hillocks, and in the waste grounds at Yucatan which are called *cuyos*. The owner of the Xanchann hacienda has sent several pounds of *atuc* fibre to a New York firm, which immediately gave an order for 2,000 bales, offering the price of 15 cents per pound. The fibre, it appears, can be substituted for flax, or be mixed with linen yarn for the manufacture of fine tissues.

The *atuc* grows like the henequen (sisal hemp). In growing, it successively loses its lower leaves, and forms a trunk which grows to a height of four metres and sends out branches, which give to the plant the appearance of a tree. It produces, till its decay, several thousands of fibrous leaves averaging 62 centimetres in length.

THE EXPORT TRADE OF THE CONGO.

The following particulars of the export trade of the Congo during the year 1888 are extracted from the *Bulletin Officiel de l'Etat Indépendant du Congo* for the month of April last:—

Special Exports.

The total value of the special exports, being those from the Independent State of the Congo, during 1888, was 2,609,900 francs. The principal articles exported, together with their values, were as follows:—Ground nuts, 2,928 francs; caoutchouc, 280,929 francs; copal, 7,006 francs; palm oil, 463,125 francs; ivory, 1,096,240 francs; palm nuts, 754,791 francs.

General Exports.

The total value of the general exports, which include those from the Congo Free State together with the French and Portuguese possessions in the Congo, was 7,332,348 francs. The proportion taken by the different European countries was as follows:—

Netherlands, 4,343,177 francs; England, 337,927 francs; Portugal, 563,350 francs; Germany, 312,003 francs; Belgium, 249,844 francs; and France, 23,181 francs.

INDIAN TRADE WITH RUSSIA.

The following notice appeared in the *Englishman's Overland Mail* (Calcutta) for the 27th March last:—

"One of the consequences of the imports to India of Russian petroleum would seem to have taken the form of an extension of the direct trade with Russia in indigo. In this, as in many other departments of commerce, England is to a great extent losing its place as a distributing centre. Thus, last year Russia took 1,623 cwt. of Indian indigo, valued at over five lakhs of rupees. The figures for the previous 12 months were 46 cwt., of the value of nearly one and a quarter lakhs. The direct trade that is springing up between India and the European continent is one of the most noticeable features of the commercial situation of India."

THE CINCHONA TRADE OF BENGAL.

The *Times* of India for the 29th March last, reviewing the administration report of Bengal for 1887-88, says:—

The cinchona trade continued favourable, and the policy of replacing the red bark or cinchona febrifuge-yielding plant by the *calisaya ledgeriana* and hybrid varieties which yield quinine, was steadily pursued. The year was marked by the discovery of a process for the manufacture of sulphate of quinine, which it is expected will be indistinguishable from the best brands of European manufacture. In other respects also the manufactures, mines, and other industries of the Presidency show a general improvement all round.

THE MINERAL RESOURCES OF BRITISH COLUMBIA.

See Board of Trade Journal for May, p. 553.

MINERAL EXPORTS FROM VICTORIA DURING 1888.

The *Cape Argus* (weekly edition) for the 27th March last states that the quantity of uncoined gold exported from Victoria during 1888 was 60,632 oz.; antimony, 7 tons; arsenic, 99 cwt.; coal, 325 tons; copper, 700 cwt.; pig iron, 35 tons; lead ore, 3 tons; quicksilver, 13,510 lb.; silver, 26,034 oz.; amalgam (gold and silver), 6,258 oz.; sulphur, 1,297 cwt.; tin ore, 12 tons; tin sand, 160 cwt.; and ores, mineral clays, &c., unenumerated, 287 tons.

ALCOHOL FROM BANANAS AND TAMARINDS IN NEW CALEDONIA.

Efforts have been made at Koc to distil alcohol and wine from bananas, which grow well in New Caledonia. These have not resulted in anything of importance. The banana wine was a passable cider, and the brandy had no particular quality to recommend it. On the contrary, the tamarind tree has produced an excellent brandy, manufactured in the following way:—The fruit, picked a little before it was ripe, was crushed in water, and the whole allowed to ferment. From 13-50 kilos, of fruit eight litres of brandy at 55°, of good quality, were produced. A very remarkable fact is the absence in the tamarind of the essential oils, which pollute almost all fruit or grain alcohols below a certain degree. Besides alcohol, there can be extracted from the fruit of the tamarind a certain quantity of tartaric acid. Agave fibre is another vegetable product, which was introduced several years ago, and which is beginning to be of value in New Caledonia. In short, the colony is one which, with care, cannot merely be made to produce corn and wine for its own consumption, but may become a centre of commercial activity from which agricultural and horticultural products may be exported to other countries.

DR. DECHAMBRE'S ENCYCLOPEDIA COMPLETE.

At the Academy of Sciences' sitting of May 13, Dr. Verneuil announced the completion of the *Dictionnaire Encyclopédique des Sciences Médicales*, formerly edited by Dr. Dechambre, who died in January 1886. This immense work, treating not only of medicine but also of pharmacy and allied sciences, consists of 100 volumes

octavo, and is considered the most complete of its kind. Dr. Verneuil remarked, while paying a tribute to the memory of his late fellow academician, that the *Encyclopædia* had almost as many subscribers abroad as at home, Great Britain and the United States having taken a considerable number of copies. — *Chemist and Druggist*.

THE ANTIQUITY OF BRONZE.

According to an analysis made by Professor Berthelot, the sceptre of Pepi I., an Egyptian king of the sixth dynasty, consists of almost pure copper. The sceptre in question belongs to the British Museum, and as a special favour to Minister Waddington, the Museum authorities consented to give a portion of the precious object to be submitted to Professor Berthelot for analysis. Some filings from the inside—the sceptre is hollow—weighing less than $\frac{1}{2}$ gram, or exactly 0.0248 gram, were detached for examination. The Professor has found them to consist of a reddish metal, slightly oxidized, and a quantitative analysis, correct within one-tenth of a milligramme, has proved the substance to be pure copper, without any admixture of tin, and doubtful traces of lead. His conclusions are that, since archaeologists agree in placing Pepi's reign at about 1400 years before the Christian era, the introduction of bronze, both in the old world and in America, occurred very nearly at the same period, and at an epoch not much farther back than fifty or sixty centuries from the present time. — *Chemist and Druggist*.

THE TRANSVAAL GOLD FIELDS.

In the course of an article on these gold fields, the special correspondent of the *Engineering and Mining Journal* states that these fields are very severely handicapped by want of transport facilities. It not only takes months to get a waggon from Ladysmith, the terminus of the Natal railway, to Barberton, but the cost of freight is 10s. to 30s. per cwt. There is not a railroad in the country, nor any reasonable prospect of one.

There is no timber for mining purposes in the Barberton district, and none for fuel for motive power. There is, however, abundance of splendid coal in the country, but it is 50 miles off at least, and on the "High Veldt," so that for metallurgical purposes and steam raising its cost would be prohibitory. When the railroad is made it will pass on its way to Johannesburg right through these coal fields; at present companies are forced to place their mills on banks of streams and use water power to run them. This may entail transport from the mine by means of oxen—a slow and unreliable method. Steam tramways are about to be tried in one or two cases, but the correspondent thinks that electric propulsion must eventually come. For labour the mines are dependent on the natives, who are unskilled and unreliable, but make on the whole good rough workmen. Mining is primitive, and many properties have been opened by means of adits, but work cannot be long continued by this means. The milling of the auriferous ores is bad in all cases, and only such free gold as is caught on copper plates is saved. The pyrites, which generally is extraordinarily rich, is only partially, if at all, saved by blankets, the balance being irrecoverably lost. This pyrites is sometimes ground with mercury in pans, which only yields a portion of the gold contents. Chlorination can only be adopted when the fuel question is satisfactorily settled. Ore concentrators are not yet in use.

The Transvaal Gold Law is very vexatious in petty taxes, which aggregate into a large percentage of the gold produced, the worst feature in these laws being the fact that there is no absolute security of title.

The Transvaal Government has given concessions or monopolies for the sole rights to manufacture certain articles and use certain processes, such as the manufacture of iron, of sporting and blasting powder (which is so bad that it is useless), of dynamite and nitro-glycerine compounds (which has been nullified by permission to import some thousand cases, which will last for some years); to the Newberry Vautin Company for the exclusive right to employ chlorine or bromine to extract gold from its ores; and, lastly, the sole right to electrically transmit power.

In conclusion, the correspondent gives details of the cost of mining, and as to how the mines are floated. He protests against the ridiculously exorbitant prices paid for mere mining properties. At the same time the future, he thinks, is hopeful, and he expects to see the gold production from now known properties eventually rise to 50,000 oz. per month.

THE GOLD PRODUCTION OF THE TRANSVAAL.

A. Götz. *Chem. Zeit.* 13, 297, 313, 314.

The production of gold is rapidly increasing, as is shown by the following figures representing the value of the exports from the English colonial harbours, Delagoa Bay not included:—

	£
1871 to 1880.....	324,666
1881.....	17,952
1882.....	22,049
1883.....	30,157
1884.....	39,095
1885.....	68,563
1886.....	131,769
1887.....	235,487
1888.....	880,461
Total.....	1,534,773

Most of the gold from South Africa comes from the Transvaal districts; Witwatersrand, 35 miles south of the capital of Pretoria; De Kaap, 250 miles east of Pretoria; Zoutpansberg, 160 miles north

of ditto; Pilgrim's Rest and Lydenburg, 180 and 218 miles north-east of ditto; Komati, 220 miles east; Potoschefstrom, 50 miles; and Klerksdorp, 100 miles south-west of Pretoria.

The auriferous deposits of the two last districts and of Witwatersrand are conglomerate, stratified with sandstone, and are probably Devonian in age. In other districts the deposits are chiefly quartz. There are also relatively small quantities of alluvial near Barberton, in the Witwatersrand, and elsewhere. Of the districts mentioned, the gold output has been almost wholly from the Witwatersrand and the De Kaap. The production of the former in 1888 was, for the first half year, 89,514 oz., and for the second, 141,142 oz. The value of the same averaged about 3*l.* 19*s.* 6*d.* per oz. The conglomerate reefs have been traced for 45 miles; 120 companies are at work, with capital to the value of 1,000,000*l.* The outputs of the chief mines have been as follows:—

	oz.
Robinson Co., from Feb. to end of Nov. 1888....	19,680
Crown Reef, to end of Nov. 1888.....	13,246
Salisbury, from Sept. 1887 to end of Nov. 1888....	10,248
Wemmer, to the end of Nov. 1888.....	13,394
Jubilee, " " ".....	6,782
Worcester, " " ".....	1,330
Royal, " " ".....	4,692
Grahamstown, to Oct. 1888.....	3,323
Pearl, Pretoria, from Mar. to Nov. 1888.....	4,715
Wolluter, from Aug. 1887 to Aug. 1888.....	3,351
Langlaate Estate, from Jan. to Nov. 1888.....	9,044
City and Suburban, from Aug. 1887 to end of Oct. 1888.....	4,985
Heriot, from Feb. to end of Nov. 1888.....	4,517

The deposits in the Barberton districts are difficult to mine owing to want of water. The following are the productions of the chief mines in this district:—

	Oz.
Sheba Gold Mining Company.....	31,500
Republie do.....	2,274
Consort do.....	3,863
Barberton do.....	1,900
Central do.....	830
Oriental do.....	815
Moodies do, from August, 1885 to March 1888.....	22,977

The gold from this district is worth about 3*l.* 17*s.* per oz. The most important mine is the Sheba, the monthly productions of which are given from October 1887 to June 1888, the average per month in 1888 being a little under 2,000 oz.—A. W.

NOTES FROM THE CAUCASUS.

Chem. Zeit. 13, 357.

The yield of naphtha from the neighbourhood of Novorossiysk for the past year amounted to 1,200,000 pounds. There are 70 borings, belonging chiefly to the "Standard" Company, of which 14 have been bored during the past year. Only 15 per cent. of these are exhausted. Their depth varies from 25 to 100 fads, the deeper borings yielding a lighter oil than the shallower ones. The price for naphtha residues, sold on the spot, has risen to 25 copecks per pound. In the Batumi district, near Sapsa, the borings are being continued, but they are not likely to yield the quantities of oil got from the Baku region. Manganese is exported in small quantity from Tschiatour, but the cost of transport to the station Kuribiy is so great that most of the workings are abandoned. Coal from Tkibuli has made its first appearance on the market. This district is situated 40 km. north of the town Kutais, with which it is connected by a railway line. The deposits of coal are about 300 ft. above the village; they are exposed to the surface, and contain a thickness of about 8 fads of pure coal, which is very resinous, yields a large percentage of ash, but contains little carbon. A German company which proposes to make use of this coal to work up the manganese ores of the Tschiatour district for export, is expected to begin work soon. Fireproof materials, hitherto imported from England, are now made in Baku, from material found in the neighbourhood.—C. A. K.

INDUSTRIAL APPLICATIONS OF COTTON-SEED OIL.

R. Grimshaw. *J. Franklin Institute*, 1889, 191—203.

The crude oil expressed from decorticated and crushed upland cotton-seed is dark brownish-green, odourless, and having a specific gravity of .9224; refined, by treatment with alkalis, it becomes clear yellow, while unchanged in density; "boils" at 600° F., solidifies at 50° F. for summer-pressed and at 32° F. for winter-pressed oil. Oil made in Great Britain from Egyptian or Indian seed is not so clear as the American product. About 800,000 tons of cotton-seed are crushed yearly, yielding 28,000,000 gallons of oil, worth about 30 cents per gallon when refined. Of this quantity, nine-tenths are used as food, e.g., in "refined lard," salad and cooking oil; the remainder goes for soap-making, for use as an illuminant and for many minor purposes. Standing between the drying and non-drying oils, it can be employed neither as a lubricant nor as a vehicle for paint.

Forty years ago it began to be used to soften lard intended for sale in very cold climates, after which it was used in the manufacture of facitious lard for temperate climates, beef-fat being added to harden the product; and the same method is practised extensively to-day. It is claimed that such "lard" is preferable to real lard from the hog, as it is less liable to contamination from the fat from portions of the animal that cannot be considered legitimate sources of lard, and from animals more or less diseased.

The United States exported 321,523,746 lb. of "lard," valued at 22,763,921 dollars in 1887.

The cotton-seed meal left after the expression of the oil forms a good cattle food, causing the production of more and better milk and meat, and richer manure; this is attributed to the quantity of albuminoids and fat it contains. An analysis of the decorticated meal is given, together with many others of various American feeding stuffs, in the form of a table quoted from Stewart's "*Feeding Animals*." According to this it has the composition:—Water, 8.33; ash, 7.25; albuminoids, 35.75; carbohydrates (including fibre), 22.25; fat, 11.65 parts per cent. respectively, while its feeding value per ton of 2,000 lb. is 15 dollars as against 12.40 dollars for meadow hay, 24 dollars for dry brewers' grains, and 35 dollars for linseed cake. The ashes of the cotton-seed hulls are used as a fertiliser, and it is stated that 1 ton of them is equal to 4½ tons of hard wood ashes and to 15 tons of leached hard wood ashes. The hulls are also freed from their fibre, which is used in paper-making, and then form an excellent cattle food. A table is given in the form of a genealogical tree showing the yield of these and other products from 1 ton (2,000 lb.) of cotton seed. The two chief items are crude oil 280 lb., and hulls 891 lb.—B. B.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

6391. W. Hucks. Method for separating solids from liquids. Complete Specification. April 15.
 6770. H. Finch and J. Mackenzie. Metallic hampers or skips for carboys and other articles. April 23.
 6861. J. Price. Apparatus for expelling liquid from and compressing semi-fluid or plastic substances. April 24.
 6938. J. C. Fellner and C. Ziegler. Travelling platforms, beds, or trucks for kilns or ovens for drying, burning, baking, and similar operations. Complete Specification. April 25.
 6955. G. E. Dorman. Pumps for producing high vacuums. April 26.
 6989. E. Edwards.—From G. Lange and L. Rohrmann, Prussia. Apparatus for treating gases by liquids. April 26.
 7015. J. Dixon and E. W. Walker. Jacketed pans for melting wax and other substances. April 26.
 7035. H. B. Fletcher. Apparatus and appliances for melting metals and other fusible substances by means of water-gas or other gaseous fuel. April 27.
 7087. J. Hill. Presses for compressing semi-fluids into solids. April 29.
 7110. J. Jackson. Apparatus for lifting malt and other liquors—partly applicable to other purposes. April 29.
 7111. H. Walker. Pyrometers. April 29.
 7119. C. Salomon. Drying, desiccating, and roasting apparatus. Complete Specification. April 29.
 7203. H. Roeske. Improvements in filters. April 30.
 7343. J. Foster. Vacuum distilling and evaporating apparatus. May 2.
 7516. W. W. Tyfe. Filters. May 1.
 7548. C. Salomon. An improved process for drying, desiccating, and roasting. Complete Specification. May 6.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

7667. B. Finch. Liquid fuel furnace bars. May 8.
 9667. J. G. Lorraine. Method and apparatus for filtering fluids. May 1.
 10,069. W. Ackroyd and T. H. Ackroyd. Apparatus for consuming smoke and economising fuel. May 15.

13,263. O. Murray.—From W. Lorenz. Method and apparatus for working pressure pumps. May 1.

17,809. W. R. Watson and R. A. Robertson. Apparatus for evaporating, concentrating, and distilling liquids. May 15.

18,138. J. Walworth. Furnace for production of hot air. May 15.

18,383. W. R. Watson and R. A. Robertson. Apparatus for evaporating, concentrating, and distilling liquids. May 15.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

6397. B. H. Thwaite. Improvements in the use of atomised solid fuel for generating heat by its combustion, and in apparatus therefor. April 15.
 6432. F. Sanders. Improvements in retorts for producing gas. April 15.
 6567. W. Deighton. Improvements in gas-producer apparatus and appliances connected therewith, for the manufacture of water-gas and other gases. April 17.
 6659. J. von Langer and L. Cooper. Improvements in or connected with the manufacture of water gas. April 18.
 6683. H. Aitken. Improvements in treating bituminous, carbonaceous, or combustible substances to obtain gas and other products, and in the treatment of gases such as result therefrom. April 18.
 6747. W. Bliss, E. Bradbury, and A. H. Gibson. Improvements in and connected with burning gas tar or other liquid fuel in steam boiler and other furnaces. April 20.
 6805. L. Paget and C. J. Kintner. Improvements in the manufacture of hoods or mantles for burners used in incandescent gas lighting. Complete Specification. April 23.
 6833. B. H. Thwaite. Improvements in methods of generating water gas and other like combustible gases for heating, lighting, and motor purposes, and in apparatus therefor. April 24.
 6840. J. P. Cornett. A process connected with the cleansing of the waste fluid from coal-washing machines and the recovery of products therefrom. April 24.
 6854. H. W. Leonard. Improvements in means for feeding fluid fuel to furnaces, particularly applicable to the furnaces of brick kilns. Complete Specification. April 24.
 6917. J. N. Flesch. Method of rendering petroleum less explosive and improving its illuminating power. April 25.
 6920. C. Kreissig and O. Seim. Method of producing an increased light effect of gas, paraffin, and other flames. Complete Specification. April 25.
 6937. C. J. Langley. Improvements in artificial fuel. April 25.
 7044. A. Harkness and W. T. Harkness. An improved method of and apparatus for causing complete combustion of fuel in furnaces for heating purposes, and also effecting the abatement of smoke nuisance. April 27.
 7054. T. Walrond-Smith. Improvements in the manufacture of water-gas, and apparatus for that purpose. April 27.
 7092. J. Byrom. Improvements in gas-lighting. April 29.
 7152. H. J. Allison.—From A. G. N. Vermilya, United States. Improved process and apparatus for generating heat. Complete Specification. April 30.
 7159. J. F. Halligan. An improved apparatus for carburetting gas. April 30.
 7222. O. Peischer. Improved means of utilising waste heat in fires. May 1.
 7227. J. Elliott. Improvements in charging machines for gas retorts. May 1.
 7231. J. E. Winspear and R. Waugh. An improved time-recording candle. May 1.
 7252. J. von Langer and L. Cooper. Improvements in or connected with the manufacture of "water," "Siemens," "producer," or other such gases, and in apparatus connected therewith. May 1.
 7256. W. Hubbard. Improvements in the manufacture of coal briquettes or compressed fuel. May 1.
 7424. A. M. Chambers and T. Smith. Improvements in coke ovens, and in methods of and apparatus for collecting and utilising the products of combustion from such coke ovens. May 3.
 7551. H. J. Newcome. Condensing and purifying and abating smoke from ordinary fires. Complete Specification. May 6.
 7559. J. T. Ellis. Improvements in apparatus for condensing smoke in the furnaces of steam and other boilers. Complete Specification. May 6.

7532. W. E. Gedga.—From P. J. Leteneur. Improvements in making artificial fuel. May 6.

7541. W. Walker.—From C. H. Seymour. Improvements in the manufacture of gas, and apparatus therefor. May 7.

7544. J. T. Key. Improvements in the manufacture of gas. May 7.

7553. C. Dubois. Obtaining useful products from refuse or residues of gas purifying, and apparatus therefor. Complete Specification. May 7.

7559. J. Quaglis. Improved process and furnace for the preparation of calcin (crude gas) according to Leutgen's method, by the combined use of water, coal-gas, wood-gas, oil-gas, or natural gases and generator gas. May 7.

7741. G. W. Hart. A process and apparatus for manufacturing hydrocarbon gas. May 9.

7781. A. M. Hay. Improvements in the process and apparatus for producing oil-water gas. May 9.

7792. J. Broad and G. C. Fowler. Improvements in night and other similar lights.

7795. G. A. Cannot and L. N. Frère. Improved compound adapted to absorb petroleum or other combustible liquids and wastes for the production of artificial fuel. May 9.

7812. G. Rose, A. Baird, and M. B. Baird. Improvements in the method of and apparatus for the manufacture of water-gas. May 10.

7843. T. Ellis. A fire-light. May 10.

7847. R. T. Baxter. Improvements in the manufacture of water-gas. May 10.

7854. C. P. Armstrong.—From G. Jaumez, France. An improved apparatus for manufacturing carburetted air gas. May 10.

7876. E. Patterson. Improvements in oxidising coal gas for illuminating purposes when burned by the ordinary burner. May 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

6432. B. H. Thwaite. Gaseous fuel-producing apparatus. May 1.

9266. G. A. Page and R. Fallnicht. Improved firelighter—"artificial resinous pine." May 1.

11,677. G. Frank. Manufacture of compressed artificial fuel. May 15.

12,377. G. Frank. Artificial fuel. May 8.

15,799. W. Eacrett. An indestructible firelighter.

1889.

2914. J. D. Averell. Apparatus and process for manufacturing gas. May 15.

5132. T. H. Gray. Treatment of mineral oils. May 1.

5134. G. H. Turnbull. Trays or grids of gas-purifying apparatus. May 8.

5181. W. M. Cash. Apparatus for manufacture of illuminating and heating gases. May 15.

5389. A. J. Boulé.—From H. G. Weber. Manufacture of artificial fuel. May 8.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

6683. H. Aitken. See Class II.

6726. N. McFarlane Henderson. Improvements in and connected with retorts for the destructive distillation of shale or other oil-yielding minerals. April 20.

6993. O. C. Hagemann. Improvements in nitrifying phenols and other similar bodies. April 26.

7634. J. Armour and H. Armour. Improvements in and connected with retorts for distilling shale or other oil-yielding minerals. May 7.

COMPLETE SPECIFICATION ACCEPTED.

1888.

7334. F. Lennard. Distillation of tar, &c., and apparatus therefor. May 15.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

6434. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig, Germany. Production of an imide compound of fluoresceine chloride and of colouring matters therefrom. April 15.

6435. O. Imray.—From the above. Production of colouring matters. April 15.

6488. J. Dawson. Process for the separation of thioparalulidines (thiodines) by treatment with sulphocarbon. April 16.

6761. M. Honig. A process and apparatus for obtaining pure indosin from commercial indigo, and from by-products or raw materials containing indigo. April 20.

6777. J. E. Bedford. Improvements in the manufacture of colouring matters. April 23.

6778. J. E. Bedford. Improved apparatus for the production of colouring matters. April 23.

6791. P. Mounet. The preparation of thiophthaleines and the new colouring matters which are derived therefrom. April 23.

7057. S. Pitt.—From L. Casella and Co., Germany. The manufacture of oxyethers of alpha-naphthylamine, and their sulpho-acids and dyestuffs derived therefrom. April 27.

7314. B. Willeox.—From The Farbenfabriken vorm. F. Bayer and Co., Germany. The manufacture of diamidodiphenylene oxide, and of direct-acting dyestuffs therefrom. May 2.

7559. C. D. Abel.—From The Actien-Gesellschaft für Anilinfabrikation, Germany. Manufacture of green and violet colouring matters. May 6.

7587. A. Bang.—From Messrs. Dahl and Co., Prussia. The production of azo-colouring matters from diamidodibenzylbenzidine and diamidodibenzyltoluidine. Complete Specification. May 7.

7588. A. Bang.—From Messrs. Dahl and Co., Prussia. The production of paranitrobenzylsulpho acid, and also azo-colouring matters from the amidobenzylsulpho acid corresponding to this nitric acid. May 7.

7802. B. Willeox.—From The Farbenfabriken vorm. F. Bayer and Co., Germany. The manufacture of azo dyes and of materials therefor. May 9.

7857. O. Imray.—From The Faberwerke vorm. Meister, Lucius, and Brünig, Germany. Manufacture of a new colouring matter of the induline series. May 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9600. C. D. Abel.—From The Farbwerke vorm. Meister, Lucius, and Brünig. Colouring matters. May 15.

16,133. H. H. Leigh.—From R. G. Williams. New colouring matters. May 1.

1889.

16. A. Deminger. Preparation of nitro and amido phenols from the corresponding amides. May 15.

4904. S. Meyer. Manufacture of para-dioxybenzol in yellow staple crystals. May 1.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

6793. The Société Simonis and Chapuis. A new or improved machine for drying and carbonising wool and other textile matters in combination with an elevator and a purifying and cleaning apparatus. Complete Specification. April 23.

6827. H. Ledger. See Class VI.

6836. S. Cooper and T. Cooper, jun. Improved apparatus to be employed in the manufacture of wood wool. Complete Specification. April 24.

6890. R. Hardman. Improvements in dressing yarn for weaving, and in apparatus employed therefor. April 25.

7058. B. W. Weatherdon.—From T. A. Compere. *See* Class IX.

7090. C. Dreyfus and J. Robinson. Improvements in and relating to the manufacture of india-rubber or waterproof textile fibres and fabrics. April 29.

7315. J. T. Pearson. Improved means of and apparatus for humidifying fibrous substances. Complete Specification. May 2.

7715. C. H. Bine and J. H. Noad. A process for waterproofing and preserving textures and other materials. May 8.

7877. B. Ellinger. Improvements in the manufacture of coloured cotton weft pile fabrics. May 11.

COMPLETE SPECIFICATION ACCEPTED.

1888.

9429. S. Mason, jun. Apparatus for drying and ageing spun cotton, &c. May 15.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

6827. H. Ledger. Improvements in the process of obtaining, treating, and bleaching of fibres and fibrous materials from plants and textile fabrics, and materials of vegetable origin, and the recovery of waste products therefrom. April 24.

6876. V. D'Aoust. Improvements in apparatus for dyeing wool on bobbins and textile fabrics in the like form. April 24.

7100. F. B. Gonty. Improvements in apparatus for the use of dyers, bleachers, and others for boiling, dyeing, fastening, and finishing colours upon textile materials. April 29.

COMPLETE SPECIFICATION ACCEPTED.

1888.

6570. E. Brasier. Apparatus for washing, discharging, bleaching, softening, &c. fibres and textiles. May 8.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

6453. W. Schlenning. *See* Class IX.

6443. E. Anec. Improvements in the manufacture of soda alum. Complete Specification. April 15.

6191. C. O. Andreac.—From A. Seyferth, Germany. Process for the purpose of cleansing crystals soluble in water from adhering mother-lye. April 16.

6668. M. Netto. Improvements in the manufacture of artificial cryolite. April 18.

6674. W. R. Hodgkinson. A process for the continuous formation of ammonia or ammonia compounds from nitrogen gas. April 18.

6710. W. P. Thompson.—From J. A. Bradburn, United States. Improvements in the process of manufacturing caustic soda or caustic potash. Complete Specification. April 20.

6968. J. Hargreaves, T. Robinson, and J. Hargreaves. Improvements in the treatment of black ash and alkali waste, to obtain sulphuretted hydrogen, sulphur, and cement, and in apparatus employed therein. April 25.

7129. A. B. Cunningham. Improvements relating to the recovery of soda from slags containing the same. April 29.

7250. E. W. Parnell. Improvements in the manufacture of hypsulphite of calcium from Leblanc alkali waste. May 1.

7374. S. W. Wilkinson. Improvements in apparatus employed in evaporating brine. May 3.

7407. J. Greenwood. Improvements in the manufacture or production of metallic sodium and of chlorine. May 3.

7491. J. R. Wylde, M. J. Hammill, and H. Auer. Improvements in the manufacture of the carbonates and hydrates of potash or soda. May 4.

7654. P. J. Davies. Improvements in sulphate of ammonia plant. May 7.

7664. H. H. Lake.—From L. Bemelmans, Belgium. Improvements relating to the production of alkaline sulphides and chloride of sulphur, and to apparatus therefor. May 7.

7690. E. W. Parnell. Improvements in obtaining ammonium sulphide from ammonium chloride and Leblanc alkali waste, and in apparatus therefor. May 8.

7716. C. F. Hine and J. H. Noad. A process for producing euprammonia. May 8.

7733. The Alkaline Reduction Syndicate, Lim., and A. B. Cunningham. Improvements relating to the recovery of soda from slags containing the same. May 8.

7901. G. Veitch. Improvements in the concentration of sulphuric acid, and in the apparatus employed therefor. May 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

7285. P. A. Mallet and T. A. Pagniez. Distilling, purifying, and concentrating ammoniacal and other liquids. May 1.

9166. H. Snilliot and H. Raymond. Production of iodine and iodine compounds. April 24.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

6393. P. Simon. Improvements in the manufacture of plate glass. Complete Specification. April 15.

6446. J. E. Mathewson.—From B. C. Tilghman, United States. Improvements relating to the ornamentation of glass, and in apparatus to be used therefor. April 15.

6565. A. Rimmer and J. H. Thomas. A manufacture being mainly a substitute for glass, and improvements connected with the making of the same. April 17.

6825. T. W. Bennett. Improvements in and relating to the manufacture of certain classes of pottery ware. April 18.

7245. W. H. Hollingshead and H. Griffiths. Improvements in and relating to decorative pottery-ware. May 1.

7387. G. Fahn. The improvement of all fire-clay goods by adding sugar to the compound known as silica and alumina. May 3.

7761. O. P. Erard and B. J. Round. An improved process for depositing metal on glass. May 9.

COMPLETE SPECIFICATION ACCEPTED.

1888.

7183. W. T. Turner. Means for "towing" or "scouring" ceramic productions in the clay or biscuit state. May 8.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

6124. J. Mobbs and H. A. Mobbs. An improved material for paving roads, and for such like purposes. April 16.

6133. W. Schlenning. Application of the residues of soda manufacture for building purposes. April 15.

6536. H. Wright de Lespaze and W. H. Shafto. Improvements in the manufacture of plaster and the like substances. April 16.

6584. G. R. King. Compounds to restrain the setting of plaster and the like. Complete Specification. April 17.

6874. J. N. Tata and J. Lyon. Improvements in the manufacture or production of mosaics for floors, staircases, walls, ceilings, and other like purposes. April 24.

7058. R. W. Weatherdon.—From T. A. Compere, Italy. An improved combination and mode of treating hemp, flax, jute, and other fibres, and employing the same for roofing tiles, buildings, and other purposes. April 27.

7162. W. Adamson. An improved combination curbing. April 30.

7943. S. Hindley and G. R. McKenzie. Improvements in the manufacture of cement for joining wood, stone, and other materials. May 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8485. R. Mannesmann. Fireproof columns. May 15.

9605. P. M. Justice.—From A. Gravelin. Plastic compounds. May 15.

1889.

3872. L. J. Cadwell. Pavements and blocks therefor. May 15.

4509. W. Davidson. Kilns for drying granular substances. May 1.

4806. Sir E. J. Harland, Bart. Manufacture of elastic tiles. May 8.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

6430. C. Wells. Improvements in the manufacture of tin-plates. April 15.

6460. J. A. Conrad. Improvements in or relating to the treatment of auriferous alluvium. April 15.

6521. G. A. Jarvis and W. P. Thompson. Improvements in or relating to the manufacture of sodium or (with certain precautions) other metals. April 16.

6594. H. F. Taylor. Improvements in apparatus for coating with tin, lead, or other metals or alloys. April 17.

6684. H. Aitken. Improvements in connection with blast furnaces or other large furnaces or fires for utilising the otherwise waste heat thereof in the obtaining of products from sea water or brine. April 18.

6708. G. A. Jarvis and W. P. Thompson. Improvements in or relating to the manufacture of aluminium, alloys of aluminium, and of other metals. April 20.

6882. F. Knowles.—From T. C. Sanderson, Portugal. Improvements in effecting the separation of gold from antimony. April 24.

6925. A. H. Holdich. An improved form of stopper or valve for controlling the flow of steel from the ladle or reservoir used at steel works. April 25.

7013. L. P. Devancelle. Improvements in the manufacture of aluminium and alloys thereof. April 26.

7035. H. B. Fletcher. See Class I.

7047. W. F. Jackson and W. Galbraith. Improvements in the manufacture of steel. April 27.

7066. W. H. Rickard and T. J. Rickard. Improvements in apparatus or machinery for coating steel, iron, or other plates with tin, lead, or other metals or their alloys. April 27.

7132. L. Imperatori. Manufacture of compressed compound blocks of substances containing iron and of carbonaceous matter, and the use of such blocks in the production of cast steel and ingot iron. Complete Specification. April 29.

7181. E. Walsh, jun. Improved method of and apparatus for condensing zinc vapours and collecting the metallic zinc therefrom. Complete Specification. April 30.

7271. C. Netto. Improvements in and relating to apparatus for condensing sodium and other vapours. May 1.

7311. R. Heathfield. Improvements in apparatus or machinery used in coating metal sheets with metal or alloys. May 2.

7353. N. Lébedeff. Improvements in and means or apparatus for the extraction of metals from metallic ores in matters containing metals. May 2.

7407. J. Greenwood. See Class VII.

7443. J. McCann. Improved blast furnace blocks and tuyeres. May 4.

7459. J. Clark. Improvements in the process of obtaining aluminium and alloys of aluminium with other metals. May 4.

7468. C. F. Barker. Improvements in the amalgamation of the precious metals, and in the means or apparatus employed therein. May 4.

7514. C. Netto. Improvements in the manufacture of sodium and potassium, and in apparatus therefor. May 4.

7666. G. Bamberg. Reducing aluminium by the action of molten metals, particularly iron, zinc, copper, and lead, on chloride of aluminium or double chloride of aluminium and sodium. May 8.

7667. G. Bamberg. Reducing aluminium by the action of zinc vapour on chloride of aluminium or double chloride of aluminium and sodium. May 8.

7778. F. F. Jones. Improvements in the process of and apparatus for reducing aluminium, its alloys, and other metals from their ores. May 9.

7832. F. Merricks and G. A. Nussbaum. Improvements relating to apparatus for the separation or extraction of metals from their ores by amalgamation. May 10.

7886. W. Potter. Improvements in the hardening of steel. May 11.

7887. C. Lingard. Method of casting steel articles in sand moulds to harden in water after annealing. May 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

7408. A. J. Boulton.—From G. Manet and C. Manet. Electrical cartridges for firing the charges of blast holes. May 1.

8042. G. Siddell. Appliances for rotating ingots or large forgings while under forging press or steam hammer. May 8.

8423. G. Siddell. Apparatus for turning ingots, &c. while under the action of the steam hammer or forging press. May 1.

8439. W. Eyre. Forged hollow weldless shells. May 15.

8743. L. Q. Brin. Plating metals with aluminium, and producing alloys thereof. May 15.

8783. R. Evans. Apparatus for consolidating quantities of scrap metal. May 1.

8961. W. H. Beck.—From A. Lévy. Process for depositing metals from their salts. May 8.

9392. A. Wilson and S. Ontes. Apparatus for manipulating arm or plates and other large ingots in forging presses. May 8.

9886. C. A. Burghardt. Reduction of zinc oxides. May 15.

10182. S. Alley and J. A. MacLellan. Apparatus for making moulds for casting. May 15.

12298. W. P. Thompson.—From A. Rovello. Obtaining copper and other metals from solutions of the salts of same, and apparatus therefor. May 15.

18842. L. Burdon. Ingots for making seamless plated wire. May 1.

1889.

1418. G. Kruss. Decomposing commercial nickel and its salts, and galvanically coating objects with pure nickel. May 8.

2031. S. McColley Godfrey and J. B. Allen. Impregnating metals and making alloys. May 15.

2279. A. J. Boulton.—From O. Hofmann and P. Linke. Metal alloy for moulders' tools. May 8.

4428. N. C. Cookson. Coating iron with antimony. May 1.

4556. C. Jones. Treatment of steel. May 15.

5639. F. Knaffé. Process and apparatus for manufacture of steel ingots and castings. May 8.

5667. J. H. Darby. Manufacture of ingot iron or steel, and production of highly phosphoric slag. May 8.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

6745. M. Kiliani. Improvements in the method of and means for electrolysis of substances in a state of fusion. April 29.

6848. H. W. Boulbee. Improvements in the treatment of galvanised sheets of metal, and in apparatus therefor. April 24.

6865. G. E. Heyl. Improvements in secondary batteries. Complete Specification. April 24.

6942. J. Zacharias and F. Marx. Improvements in electrical accumulators or storage batteries. April 25.

7002. T. H. Hicks. Improvements in electric secondary or storage batteries. Complete Specification. April 26.

7005. A. Schanschoeff. Improvements in galvanic batteries. April 26.

7215. C. B. Askew and J. K. Pampelly. Improvements in secondary batteries. April 30.

7356. C. Maltby-Newton. Improvements in galvanic or primary batteries. Complete Specification. May 3.

7428. C. Pollak. Improvements relating to electric accumulators or secondary batteries, and to the manufacture of plates or electrodes therefor. May 3.

7568. G. H. Jones. Improvements relating to electric batteries. May 6.

7597. C. H. Mehner. Dry galvanic cells. Complete Specification. May 7.

7619. W. J. Starkey Barber-Starkey. Improvements in and connected with electric batteries. May 7.

7628. Mix and Genest, Limited. Improvements in primary and secondary elements. Complete Specification. May 7.

7647. S. S. Wheeler. Improvements in electric motors and dynamo-electric machines. Complete Specification. May 7.

7719. P. Schoop. Improvements in electric or galvanic elements or cells. May 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

6893. E. C. Walker. Electro-magnetic and magneto-electric generators. May 15.

6907. M. Immisch. Storage batteries. April 17.

8905. H. Lahousse and Co. and C. Collé. Electric batteries. April 24.

9854. L. Bristol. Secondary batteries. May 8.

9910. G. Kapp. Continuous current dynamo-electric machines. May 15.

18,494. J. L. Roberts and H. L. Brevoort. Galvanic batteries. May 15.

1889.

1418. G. Kruss. See Class X.

5176. E. A. Sperry. Improvements in electrical installations. May 15.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

6601. J. H. Casey. An improved compound for cleaning paint, veneer, varnish, and the like. April 17.

6877. L. Gismondi. New or improved apparatus for extracting oils from seeds or the like. April 24.

7098. F. Crossley. Improvements in washing or cleansing compounds. April 29.

7554. A. J. Boulton.—From J. Lafage, France. Improved process for extracting the oil from the livers of cod and other fish. May 6.

7617. W. Smith. An improved soap. May 7.

7618. W. Smith. An improved salve or pomade. May 7.

7834. W. Johnstone. Improvements in the manufacture of soap. May 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

6949. W. A. Mitchell and O. C. Hagemann.—Partly from M. von Schmidt. Purification of oils and fats, and obtaining of useful products therefrom. May 8.

8366. J. Jeys. Manufacture of soap. April 24.

9477. W. T. Hicks and J. Elliott. Lubricating composition. May 1.

1889.

5028. J. Annull. Lubricating compound. May 1.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

6581. G. Hand Smith. Improvements in the treatment of gum copals, gum resins, and other gums for the manufacture of varnishes and other solutions for coating surfaces and for other uses. Complete Specification. April 17.

6589. J. J. Hummel. New or improved red dye or pigment, and process for making and applying the same. April 17.

6815. R. W. E. MacIvor, F. A. Darlington, G. Paul, and J. Allan. Improvements in the production of white lead or carbonate of lead. April 23.

7051. A. Washington. An improved paint. April 27.

7154. J. Thom. Improvements in making white lead. April 30.

7156. J. Macfarlane. Improvements in obtaining yellow pigments. April 30.

7379. W. Smartt. Improvements in the production of vulcanised india-rubber and analogous materials for use as boot and shoe soles, tyres, and other purposes. Complete Specification. May 3.

7542. E. N. Norminton. The manufacture of copal oil varnish to dry without the aid of any metallic driers of any kind. May 10.

7881. N. B. Denny. Preserving and preventing the fouling by marine growths of submerged wood or iron, to be named "the zoeus anti-fouling paint." May 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

4637. R. Seabrook. Anti-fouling compounds for coating vessels. May 1.

5703. M. Gauzl and J. Mössner. Solution for rendering cloth, felt, paper, &c. waterproof. May 15.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATION.

6703. A. F. S. Grant and W. Francis. Tanning. April 20.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

10,482. J. Rivage and J. B. Matrod. An improvement in tanning. May 8.

1889.

2771. W. Gridley and F. B. Pike. Manufacture or treatment of gelatinous substances. May 1.

XVI.—SUGARS, STARCHES, GUMS, ETC.

APPLICATIONS.

7131. H. A. Hughes. The manufacture of sugar liquor from sugar cane by diffusion. Complete Specification. April 29.

7517. G. Adant. Improvements relating to apparatus for the manufacture of sugar. May 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9183. G. Fletcher.—Partly from C. A. Matthey. Apparatus for use in boiling and evaporating sugar and other liquids. May 1.

1889.

76. O. Lenz. Manufacturing colourless maltose syrup. May 15.

4741. H. Barker. Manufacture of gluten and starch. May 8.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

6918. C. R. Bonne. Improvements in the manufacture of "German yeast." April 25.

7049. W. W. Mutter and W. Dawson. Improvements in or relating to distillers' safes. April 27.

7110. J. Jackson. See Class I.

7338. C. R. Evans and T. Green. Tomato wine. May 2.

7598. W. G. Hicks. The use of pure oxygen gas for assisting the fermentation of beer or other fermentable liquids. May 7.

7909. A. Perry. Improvements in the treatment or preparation of rice and other grain or cereals for brewing and other purposes, and in means or apparatus employed therein. May 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

2735. W. S. Squire. Apparatus for purifying crude spirit. May 1.

6026. W. Hucks. Treatment of brewers' or distillers' worts. April 3.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—CHEMISTRY OF FOODS.

6436. G. Bischof. Improvements in apparatus for sterilising water and rendering it suitable for drinking and other uses. April 15.

6943. F. J. Chevet. Improvements in the manufacture of desiccated soup, and in packing the same. April 25.

6884. A. Vászrhelyi and J. Jámor. Improvements in the method of preserving milk. April 26.

7320. G. Dixon. Improvements in or relating to preserving food and other organic matters. May 2.

B.—SANITARY CHEMISTRY.

6522. J. S. Rigby and J. Rigby Wyld. Improvements in pressing or filtering and separating from each other the solid and liquid constituents of mud and other semi-fluid mixtures. April 16.

6528. H. H. Lake.—From J. Hirshfeld, United States. Improvements relating to the treatment of feculent matter, and to apparatus therefor. April 16.

6576. J. P. Cornett. An improved process connected with the treatment of sewage and the utilisation of products therefrom. April 17.

6994. C. H. Harsey (for The Barry Patent Manure Co., Ltd.). Improvements in the clarification or purification of sewage and other foul waters of analogous nature. April 26.

7385. J. Bentley and T. Thorp. Improvements in the disposal of sewage and ashpit refuse. May 3.

7630. J. Davis. Improvements in and relating to means for purifying water. Complete Specification. May 7.

7699. G. A. H. Gabel. An improved process for the extraction of ammoniacal nitrogen from sewage. May 8.

C.—DISINFECTANTS.

6411. F. W. A. Hille. Improvements in disinfectants, their manufacture, and their use. April 15.

6772. T. Hambly. Manufacturing fumigating tobacco paper. April 23.

7824. G. H. Jones. An improved disinfectant and antiseptic. May 10.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—CHEMISTRY OF FOODS.

1888.

7475. E. J. T. Digby. A new alimentary compound and means of producing same. May 15.

15,813. R. S. Baxter and G. D. Macdonald. Manufacture of seed cake or cattle food from cotton seed. May 8.

B.—SANITARY CHEMISTRY.

1888.

6405. F. R. Lipscombe. Apparatus for precipitating organic or inorganic matter in solution or suspension, and for purifying the liquid afterwards and treating the precipitate. May 8.

9091. J. A. Muller. Prevention of fermentation or decomposition of animal or vegetable substances, and apparatus therefor. April 24.

15,321. H. Wollheim. Clarifying, purifying, disinfecting, and utilising sewage and foul or waste waters. May 1.

C.—DISINFECTANTS.

1888.

16,242. H. Wollheim. Reagent for disinfecting, preservative, or remedial purposes. May 1.

XIX.—PAPER, PASTEBOARD, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8840. A. Boake and F. G. A. Roberts. Discharging excess of bleaching agent from paper pulp after bleaching. April 24.

8981. C. D. Aria. Treatment of paper, paper pulp, cardboard, &c. to render same impervious to acids, water, air, mineral oils, gases &c. April 24.

9106. J. H. Annandale. Preparing pulp for paper making machines, and apparatus therefor. May 8.

9321. L. G. Danielson. Improved paper, and manufacturing a paper sized on one side and unsized on the other, or more impregnated with size or glue on one side than the other. May 15.

18,753. L. Piette. Method of sorting disintegrated wood for the manufacture of cellulose, and apparatus therefor. May 15.

1889.

5247. F. Weyland. Apparatus for drying cardboard or paper. May 1.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

6494. O. J. Steinhart. Improvements in the manufacture of ethyl mercaptane. April 16.

7391. J. F. von Mering. A process for the production of a substance to be called "chloroformamide" or "chloralamide." May 3.

7530. G. Bamberg. Utilising sulphocyanide of iron as a medicinal drug in lieu of the usual ferruginous tonics; also the use of any alkaline sulphocyanide as a medicinal drug. May 6.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.*APPLICATION.*

7747. W. F. Greene. Rendering cardboard, paper, or the like impervious to the action of photographic chemicals, and therefore suitable for photographic purposes. May 9.

XXII.—EXPLOSIVES, MATCHES, ETC.*APPLICATIONS.*

6399. C. O. Lundholm and J. Sayers. Improvements in the manufacture of explosives. April 15.

6427. W. R. Hodgkinson. Improvements in explosive compositions or combinations of matters for use as blasting agents. April 15.

6459. H. E. Michelsen. An improved combined match and fusee. April 15.

6530. A. Melville, J. B. Chalmers, and G. J. Marples. Improvements in or connected with explosives. April 16.

6531. A. Melville, J. B. Chalmers, and G. J. Marples. Improvements in or connected with explosives. April 16.

6532. A. Melville, J. B. Chalmers, and G. J. Marples. Improvements in or connected with explosives. April 16.

6595. L. Cobbaert. A machine for the continuous manufacture of matches. April 17.

7004. T. Nordenfelt. Improvements in percussion fuses. April 26.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

6805. G. J. Mayer. Manufacture of quick match and other fireworks, and apparatus for covering same. April 17.

8503. E. Ducretet. Magneto-electric fuses. May 8.

9164. T. G. Hart. Explosives for use in firearms. May 15.

13,656. C. F. Hengst. Smokeless safety gunpowder. May 1.

13,912. R. Bateman. Railway fog signals. May 1.

1889.

4812. R. H. Earle. Marine distress signals or bombs. May 1.

5720. W. Kennish. Means for igniting the charge in explosive projectiles. May 15.

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 6.—VOL. VIII.]

JUNE 29, 1889.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt 1885—1886.	
David Howard 1886—1887.	
Prof. James Dewar, F.R.S. 1887—1888.	

COUNCIL FOR YEAR ENDING JULY, 1889.

President: Ludwig Mond.

Vice-Presidents:

<i>Sir I. Lowthian Bell, F.R.S.</i>	<i>David Howard.</i>
R. Forbes Carpenter.	<i>Ivan Levington.</i>
Prof. F. Clowes, D.Sc.	<i>E. K. Muspratt.</i>
Sir J. Neilson Cuthbertson.	<i>Dr. W. H. Perkin, F.R.S.</i>
Prof. James Dewar, F.R.S.	<i>Sir H. E. Roscoe, M.P., F.R.S.</i>
Dr. John Evans, F.R.S.	<i>Prof. W. A. Tilden, F.R.S.</i>

Ordinary Members of Council:

Alexander M. Chance,	<i>F. J. Rowan.</i>
James Duncan.	<i>Dr. Edward Schunck, F.R.S.</i>
A. E. Fletcher.	<i>E. C. C. Stanford.</i>
S. H. Johnson.	<i>J. C. Stevenson, M.P.</i>
B. E. R. Newlands.	<i>T. W. Stuart.</i>
B. S. Proctor.	<i>Thos. Tyrer.</i>

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	F. Jones, F.R.S.E.
Joseph Bernays, M.I.C.E.	Ivan Levington.
H. Brunner.	Prof. R. Meldola, F.R.S.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	C. O'Sullivan, F.R.S.
W. Y. Dent.	John Pattinson.
Prof. Jas. Dewar, F.R.S.	W. H. Perkin, Ph.D., F.R.S.
John Heron.	Sir H. E. Roscoe, M.P., F.R.S.
D. B. Hewitt, M.D.	John Spiller.
David Howard.	A. Norman Tate.
Prof. J. J. Hummel.	Thomas Tyrer.

Editor:

Watson Smith, The Owens College, Manchester.

ASSISTED BY THE FOLLOWING STAFF OF

Abstractors:

T. L. Bailey, Ph.D.	F. S. Kipping, D.Sc.
G. H. Beckett.	Chas. A. Kohn, Ph.D.
D. Bendix.	F. W. T. Krohn.
E. Bentz.	T. A. Lawson, Ph.D.

W. W. Haldane Gee, B.Sc.	F. W. Renaut.
C. Napier Hake.	Edward Simpson.
S. Hamburger, Ph.D.	A. J. Smith, B.Sc.
Oswald Hamilton.	Oscar J. Steinhardt, Ph.D.
John Heron.	A. L. Stern, B.Sc.
Bertram Hunt.	A. Studer, Ph.D.
C. C. Hutchinson.	Bertram Thomas.
D. E. Jones, B.Sc.	Eustace Thomas.
W. E. Kay.	V. H. Veley, M.A.
A. J. King, B.Sc.	R. Lloyd Whiteley.
	A. Wingham.

NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those Members of Council whose names are placed in italics in the annexed list, will retire from their respective offices at the forthcoming Annual General Meeting.

Sir Isaac Lowthian Bell, Bart., F.R.S., has been nominated to the office of President; and Mr. Ludwig Mond has been nominated Vice-President under Rule 11.

Dr. W. H. Perkin, F.R.S., has been nominated a Vice-President under Rule 24; Mr. James Duncan, Mr. S. H. Johnson, Dr. Hugo Müller, F.R.S., and Dr. Edward Schunck, F.R.S., have been nominated Vice-Presidents under Rule 8; and Mr. L. Archbutt, Mr. John Brock, and Mr. John Spiller have been nominated Ordinary Members of Council under Rule 17, in the place of Mr. James Duncan, Mr. S. H. Johnson, and Dr. Edward Schunck, F.R.S., nominated Vice-Presidents.

The Treasurer and Foreign Secretary have been nominated for re-election.

ANNUAL GENERAL MEETING.

Notice is hereby given that the next Annual General Meeting will be held in London on Wednesday, Thursday, and Friday the 10th, 11th, and 12th of July next.

The following is a synopsis of the arrangements:—

Wednesday, July 10th.

Annual Meeting, Royal Institution	-	-	11.0 a.m.
Doulton's Art Pottery, Lambeth	-	-	2.0 p.m.
Lambeth Palace	-	-	3.0 p.m.
Reception	-	-	9.0 p.m.

Thurs-day, July 11th.

River Excursion (Old Swan Wharf)	-	10.0 a.m.
Saccharine Works, Hammersmith	-	11.30 a.m.
Kew Gardens	-	3.0 p.m.
Dinner at "Star and Garter," Richmond	-	6.30 p.m.

Friday, July 12th.

Truman, Hanbury's Brewery	-	11.0 a.m.
Cowan's Sugar Refinery, Barnes	-	11.30 a.m.
A.B.C. Sewage Works, Kingston	-	11.30 a.m.
Brush Electric Light Co., Lambeth	-	2.15 p.m.
Brin's Oxygen Co., Westminster	-	3.0 p.m.
Groth's Electric Tannery, Bermondsey	-	3.0 p.m.

Further details will be sent to each member with the Ballot List by post.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Post Office Orders in payment of subscriptions should in all instances be made payable at the General Post Office, London.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 21st JUNE, 1889.

- Burgess, Geo., Marsh Alkali Works, Widnes, chemist.
 Cadett, Jas., Ashted, Surrey, chemist.
 Corrie, David, c/o Nobel's Explosives Co., Ltd., Polmont Station, N.B., chemist.
 Davies, G. W., 8, Spring Hill, Stockport, teacher of chemistry.
 Dewey, Fred. P., c/o Smithsonian Institution, Washington, D.C., U.S.A., Curator, Metallurgical Department, U.S. National Museum.
 Evans, P. Norman, Ph.D., 28, Great Ormond Street, W.C., consulting chemist.
 Fenwick, Jas., Tharsis Mines, Huclva, Spain, analytical chemist.
 Glatz, Jos., Riverside Chemical Works, 485—493, Kent Avenue, Brooklyn, N.Y., chemical manufacturer.
 Hartley, R. Kent, Springwood House, Chadderton, near Oldham, chemical manufacturer.
 Pullman, John, Grove End, Chiswick, W., leather merchant.
 Rogers, Jno. Martin, 20, Frances Street, Truro, Cornwall, mining engineer.
 Schroeter, Hermann M., 1517, Montgomery Avenue, Philadelphia, Pa., U.S.A., chemist.
 Schweich, Emile, Winton Park, Northwich, Cheshire, chemist.
 Stern, Arthur L., c/o Messrs. Bass & Co., Burton-on-Trent, chemical assistant.

Woolford, Jas., Lempdes, Haute Loire, France, miner and metallurgist.

Yates, H. Noble, c/o Cowles Electric Smelting and Aluminium Co., Lockport, N.Y., U.S.A., chemist.

CHANGES OF ADDRESS.

- Cameron, R., 1/o Kelvinside; Wellpark House, Bathgate, N.B.
 Craw, Jno., 1/o Meadowbank; North Greenhill Cottage, Paisley, N.B.
 Dreaper, W. P., 1/o Clapham; Silk Crape Works, Ponders End, N.
 French, Andrew, 1/o Glasgow; Willowbank, Larbert, N.B.
 Gadd, W. L., 1/o Wath; Beech Villa, Swinton, Rotherham.
 Harrison, C., 1/o Hull; 34, Talbot Place, Sheffield.
 King, C. M., 1/o Highgate; Quinta do Caima, Estarreja Porto, Portugal.
 Lodge, A. S., 1/o Prestwich; Newchurch, near Manchester.
 Lucas, R., 1/o Kilburn; Mainzerstrasse 8, Wiesbaden, Germany.
 Lundberg, Alf., 1/o Northfleet; Ströms Bruk, Hudiksvall, Sweden.
 McCowan, Wm., 1/o Glasgow; Mount Osborne, Barnsley, Yorks.
 McEwen, T. G., 1/o Commercial Road; 73, The Grove, Stratford, E.
 McKenzie, T. E., 1/o Huclva; 10, Willowbank Crescent, Glasgow.
 Markel, Dr. Karl E., 1/o Northwich; Kirby House, Kirby Bedon, Norwich.
 Markham, A. D., 1/o London; 2, London Road, Enfield, N.
 Oddy, R. W., 1/o Molesworth Street; 60, Waterhouse, Toad Lane, Rochdale.
 O'Neill, Chas., 1/o Denmark Road; 11, Carter Street, Greenheys, Manchester.
 Parnell, E. W., 1/o Widnes; Dee Hills, Chester.
 Purser, E. T., 1/o Dublin; Dry Creek Valley, Healdsburg, Cal., U.S.A.
 Shadwell, J. E. L., 1/o Christchurch; Meadowbank, Melksham, Wilts.
 Smith, A. J., 1/o Plumstead; 58, Park Road, Greenheys, Manchester.
 Smith, Dr. J. H., 1/o Gateshead; Hottingen, Zurich, Switzerland.
 Smith, Thos., 1/o Edinburgh; 20, Crichton Road, Craigmore, Bute, N.B.
 Spoor, J. L., 1/o Tynemouth; Stone Court Cement Works, Greenhithe, Kent.
 Stanley, C. L., 1/o Wath; Oakwood Hall, Rotherham, Yorks.
 Taylor, H. E., 1/o Brand Street; 68, Ashburnham Grove, Greenwich, S.E.
 Turney, Sir John; Journals to "Springfield," Alexandra Park, Nottingham.
 Wates, E. A.; Journals to c/o Hyderabad (Deccan) Co., Secunderabad, Deccan, India.
 Whalley, L. J. de, 1/o Leytonstone; 27, Ormiston Road, Westcombe Park, S.E.
 Young, Jno. (Hanley); Journals to Gas Works, Etruria, near Stoke-on-Trent.

CHANGES OF ADDRESS REQUIRED.

- Bell, G., 1/o 17, Greenway Road, Runcorn.
 Porter, Herbert, 1/o Lime Tree Terrace, Stowmarket.

Deaths.

- Dale, John, Cornbrook, Manchester.
 Gunter, Evan, Nobel's Explosives Co., Ltd., Stevenston, Ayrshire.
 Percy, Dr. John, F.R.S., 1, Gloucester Crescent, Hyde Park, W., June 19th.
 Price, D. S., 26, Great George Street, Westminster, S.W.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

Committee:

Sir F. A. Abel.	R. Messel.
H. E. Armstrong.	B. E. R. Newlands.
W. Lunt Carpenter.	B. Redwood.
W. Crowder.	T. Royle.
W. J. Dibdin.	John Spiller.
C. Graham.	Wm. Thorp.
S. Hall.	C. R. Alder Wright.
C. C. Hutchinson.	

Hon. Local Sec. and Treasurer:

Thos. Tyrer, Garden Wharf, Battersea, S.W.

SESSION 1888-89.

July. — Annual General Meeting.

Meeting held Monday, June 3rd, 1889.

PROFESSOR JAS. DEWAR, F.R.S., IN THE CHAIR.

ON THE PURIFICATION OF ALCOHOL BY MEANS OF HYDROCARBONS.

BY W. S. SQUIRE, PH.D.

THE purification of commercial alcohol by some ready and inexpensive method is a matter of great importance. The voluminous report of M. Claude, presented in 1887 to the French Senate, accompanied by an exhaustive atlas of the quantity and kind of spirit consumed in different departments of France, demonstrated the great evils which result from the consumption of impure alcohol. Legislation based on this report was contemplated with a view to compel the purification of spirit going into consumption, but useful legislation of any kind is not likely to occur amid the frequent wreck of ministries, and the constant struggle of adventurers for place and power.

The German Government has also had this question under consideration, and it is probable that legislation in this direction will be attempted ere long. But apart from legislation there is a large actual demand for pure spirit for the manufacture of liquours and the common sorts of brandy, for medicinal purposes, and for the fortification of wines.

In Germany, where the spirit industry has attained such development as to be of national importance, the spirit as it comes from the distilleries is very impure. The distilleries are very numerous, and for the most part very small. Indeed, in many cases a distillery is part of the regular plant of a farm, the farm labourers being employed during the winter in the distillery working up the potatoes and other matters into spirit, the whole of the residual products going back to the land, either directly as manure, or indirectly as food for the cattle. This arrangement is very wisely encouraged by the Government, which favours the farmer in the matter of duty, provided nothing leaves the land, except the carbon, hydrogen, and oxygen in the alcohol, which, strictly speaking, were never in the land at all, but have been derived from the air.

It will be readily understood that small distilleries of this kind, at work only half the year, are unprovided with the apparatus necessary for producing a pure spirit. The stills are of comparatively simple construction, and, indeed, very little attempt is made to remove any impurity, except water. This of course is removed, so far as it can be easily removed, in order to keep the cost of packages and carriage as low as possible.

The spirit in this impure state comes into the market like peas, or beans, or other agricultural produce, a few casks at a time, and is bought by the rectifiers, who have usually large establishments, and work on a considerable scale.

The German rectifier commences his operations by diluting the raw spirit with water until the mixture contains from 40 to 50 per cent. of absolute alcohol. This dilution greatly facilitates the removal of the fusel oil. The dilute alcohol is then filtered through wood charcoal. Lime-tree charcoal is preferred, but the charcoal of other light and soft woods is occasionally employed. The apparatus used for this purpose is shown in Fig. 1. The plant consists of a number (usually six or eight) of wrought-iron cylinders about 3 or 4 metres high, and about 80 centimetres in diameter. These cylinders are filled with wood charcoal in small pieces, and are connected together by means of pipes and cocks to enable the requisite operations to be carried on.

The dilute crude spirit is contained in a tank above the apparatus (not shown in the drawing), and the purified spirit is received in a tank, at a lower level but above the apparatus, shown on the right hand. The cock A being open, but the cocks B, C, and D closed, as are also the cocks A², the spirit coming down the supply pipe enters the first cylinder, which it ultimately fills. The cocks E and F being closed the spirit passes down the outlet pipe, and the cock B² being open while the cocks A², C², and D² are closed, the spirit enters the second cylinder, and the same thing happens to all the succeeding cylinders. In the case of the eighth cylinder the cock E⁸ is open, and the spirit having no other outlet, for the cock B is closed, makes its way into the tank intended to receive the purified spirit.

The charcoal in No. 1 cylinder, being in contact with the most impure spirit, becomes first charged with impurities, and this cylinder must be emptied and recharged. In order to do this, the cocks A and B² are closed and the cock A² is opened. This has the effect of cutting out the first cylinder. The cock D is then opened, and the fluid contents of the first cylinder run off to be pumped back to the crude spirit tank above. While this is going on the cock G, which is intended to admit air while the cylinder is being emptied or to allow to pass out when it is being filled, must be open. The cocks G and D are then closed, and the cock C, which admits steam from the steam pipe, and the cock F, which puts the cylinder in communication with a pipe leading to a condenser, are opened. In this way any residual spirit remaining in the charcoal is given off and recovered. Lastly, the manhole is removed, the charcoal taken out, and a fresh charge introduced through the upper manhole. No. 1 cylinder is then thrown into circuit by closing E⁸ and opening B and E, No. 1 cylinder then becoming the last one. No. 2 is then thrown out of circuit in like manner, and recharged, and so on. Usually seven cylinders are at work while one is being recharged. This apparatus, although largely used, is not, so far as I am aware, figured and described in any work on spirit manufacture. It might be imagined that the vapours driven out of the cylinders by the current of steam, and condensed in the condensers, would contain a considerable quantity of fusel oil. This, however, is by no means the case; the condensed liquid has a nasty smell, it is true, but not such as would be due to a large amount of fusel oil.

Stammer in his large work, "Die Branntweinbrennerei," refers to this fact, and on that account dismisses the charcoal process as being of little use in removing fusel oil; but professors, when they write on technical subjects, are very apt to jump to conclusions on insufficient evidence, and there is one fact of which Stammer must have been aware which does not at all square with his theory. If the fusel oil and other impurities absorbed by the charcoal were

driven off in a current of steam it follows that the steam would revivify the charcoal, and there would be no necessity for recharging the cylinders with fresh charcoal. That, however, is not the case, it is necessary from time to time to remove the charcoal and heat it to redness in closed vessels. Moreover we know that charcoal possesses the property of absorbing certain gases, for instance, sulphurous acid and ammonia, in considerable quantity. Now these gases are nothing more than liquids at temperatures much above their boiling points. It does not, therefore, at all follow that fusel oil, absorbed by charcoal at the ordinary temperature, will be driven off when the temperature reaches the boiling point of the absorbed liquid.

As a matter of fact, the charcoal purifies the spirit very considerably, and manufacturers would not go on using the process if it were found in practice that the spirit came out of the cylinders pretty much as it went in. The purification is, however, not complete. When the purified spirit is rectified in a Savalle rectifier—the apparatus generally employed—an impure spirit, usually about 3 or 4 per cent. of the whole, and containing aldehyde and certain ethers with low boiling points, comes over first. This is followed by a very pure spirit, usually about 10 per cent., used chiefly for fortifying wines. Then comes the ordinary rectified spirit, and lastly an impure spirit containing impurities with high boiling points. The heads and tails of the distillation, as they are called, are usually mixed together and sold at a cheap rate, as they obviously contain impurities which the charcoal process is unable to remove.

It has long been known that oils and fats possess the power of absorbing the more or less volatile bodies which we know as odours; the odours of flowers for example. Some of these odours are very delicate; for instance, those of the violet and tuberose, which cannot be extracted from the flowers without serious injury by the ordinary process of distillation. Perfume manufacturers take advantage of this property of oily bodies to extract the odours without the use of heat. The flowers, and layers of pure grease (a mixture of lard and suet) spread on glass, are piled up in frames, and after standing some time, the odours of the flowers are absorbed by the fat, and may be extracted again from the fats by strong alcohol. This process is called "Entourage," and is largely practised in the South of France.

The same general idea has been applied to the purification of alcohol. The first person who experimented in this direction appears to have been Parsons, of New York City, who in 1869 took out a patent for purifying alcohol by means of paraffin. His process consisted in mixing strong alcohol—90 per cent. at least—with paraffin, and heating the mixture by means of a steam coil with continual agitation. He then introduced warm water so as to bring the mixture down to about 50 per cent. of alcohol, and allowed the whole to cool with continual agitation. The paraffin which separated in flakes was then filtered off from the purified spirit. He states that if the spirit is of less strength than 90 per cent. the purification is less perfect. In the following year he took out a patent for purifying spirit by causing its vapour to traverse a layer of melted paraffin, and he also claimed the use of mineral oils. So far as I am aware nothing came of these proposals, and we shall see later on that nothing was likely to come of 90 per cent. alcohol and hot melted paraffin through which the vapour of alcohol was caused to bubble.

In 1880 a patent was taken out by Simon Roessler, of Troppau, Austria, through Messrs. Haseltine, Lake, and Co., patent agents of London, for purifying alcohol, fatty matters, and wax, and for regenerating the materials employed; but whether the object was to purify the alcohol by means of the fatty matters, or the fatty matters by means of the alcohol, I defy anybody to make out. Apparently the inventor wants to do both at once.

In 1884 the subject was taken up by a Danish chemist named Bang, who became associated with M. Ruffin, of Paris. He recognised at once that the alcohol must be treated in a dilute condition. Fusel oil is but little soluble in dilute spirit, but very soluble in strong spirit; indeed,

strong spirit actually extracts fusel oil from a mixture of hydrocarbons and fusel oil, while the hydrocarbons extract the fusel oil from dilute spirit. It is a question of relative solubility. I cannot very well show you the fusel oil leaving the dilute spirit and passing to the hydrocarbons, but I can show you something of the same sort which will illustrate my meaning. If I add a dilute solution of chromic acid to a very dilute solution of peroxide of hydrogen I develop, as you see, the magnificent blue colour of perchromic acid. This substance is, as you see, soluble in water, but it is much more soluble in ether. I will add a little ether and shake up the bottle, when the layer of ether floating on the top will become intensely blue, and the water below remains almost colourless. This is what happens when hydrocarbon oils are brought into intimate contact with dilute alcohol containing fusel oils, and other substances more soluble in the hydrocarbon oil than they are in the dilute alcohol.

In Bang's first patent of 1884 he proposed to use as a purifying agent the more volatile portions of petroleum, generally known as essence of petroleum. The apparatus he constructed for the purpose is shown in Fig. 2. The dilute spirit to be purified is contained in a cylindrical vessel A, and the hydrocarbon is pumped in through the perforated pipe *t*. The small bubbles of hydrocarbon rise through the dilute spirit, abstracting the fusel oil, and collect in the glass globe *a*. From this it is conducted into the cylinder B furnished with baffle plates *c c*. This cylinder is filled with water which abstracts any alcohol which may have been mechanically carried over in the hydrocarbon. From B it is conducted to a similar cylinder C filled with chloride of calcium to abstract any water it may have taken up. From C it passes into D, filled with strong sulphuric acid, the object of which is to remove the fusel oil and other impurities by the formation of sulpho-compounds. Finally the hydrocarbon is passed through the cylinder E, filled with pieces of marble in order to remove the sulphuric acid which may be mechanically mixed with the oil.

The hydrocarbon thus regenerated is returned by the pump P to the cylinder containing the alcohol to be purified. I may remark, in passing, that if alcohol is mechanically carried over into B, and water into C, so will solution of chloride of calcium be carried over into the sulphuric acid in D, and that will make a nice mess. And, further, that greasy lumps of marble are not precisely the best means for removing concentrated sulphuric acid.

The use of volatile hydrocarbons being open to many objections, Bang and Ruffin, in 1886, substituted hydrocarbons with a higher boiling point, and devised the apparatus shown in Figs. 3 and 4. A series of cylinders, V, V¹, V², are fitted with baffle plates as at V, or filled in the middle with sponge or porous material, to facilitate the contact of the two liquids. These cylinders are filled (says the patentee; I suppose he means partially filled) with the hydrocarbon oil, and the dilute spirit is let in from the cistern A. It sinks through the hydrocarbon in V, and then passes through the outlet pipe to the top of V¹, when it again falls through the hydrocarbon, passing to V², and so on, being finally delivered at the outlet E. As the hydrocarbon in V becomes charged with impurities, it is necessary from time to time to remove it, and substitute for it that contained in V¹, which is less impure; this in its turn being replaced by that in V², which is almost pure. This is accomplished by shutting the cocks B and E, and opening the cocks C and F. The hydrocarbon then runs in the opposite direction from V² to V, and escapes at C. The hydrocarbon is afterwards regenerated by means of sulphuric acid, which takes up the fusel oils by formation of the sulpho-compounds.

A modification of the apparatus is shown in Fig. 4, which consists of a column divided into compartments by means of perforated diaphragms, and filled with porous material. The lower end of this column communicates with the hydrocarbon cistern C, while the alcohol to be purified is let in from the cistern A. The discharge pipes C and E communicate respectively with the top and the bottom of the column. There is also a pipe K communicating with the column at two different levels. The column is first filled with water up to the level of the first diaphragm O O. The

CHARCOAL PROCESS

BOWICK, - 1887.

Fig. 6.

hydrocarbon is then run in till it overflows at C. The dilute alcohol is now admitted by opening the cock B, and descends by gravity through the oil, driving the water before it, and making its exit at E. The hydrocarbon is renewed by stopping the flow of alcohol, and letting in the oil from G.

These apparatus, apparently methodical in their action, are open to a good many objections. Constructed as they are the alcohol will be very prone to go down all in one place, and this will in no wise be prevented by the perforated diaphragms so liberally introduced. I have often been struck by the unreasoning way in which perforated diaphragms are introduced into chemical plant. A whole chapter might be written on the use and abuse of perforated diaphragms. Let us suppose a fluid arriving through an inch pipe and assume the perforations to be an eighth of an inch in diameter; then 64 holes will equal the area of the pipe (the friction when thin plates are employed may be neglected), but instead of 64 holes there are usually about 610. Even if the pipe runs full bore the liquid will run through a comparatively small number of holes just where the liquid falls, but the pipe rarely runs full bore. There is usually a cock introduced to "regulate the flow," so that as a distributor the perforated plate goes for nothing. A perforated diaphragm should be so constructed that it opposes such a resistance to the flow of the liquid that the whole of the liquid cannot get through the holes until a certain head accumulates, and in virtue of the pressure of this the flow through the holes is accelerated until an equilibrium is established, and only in such a case will every hole deliver the same quantity, and act as a distributor. It is obvious, too, that the oil will be mechanically carried along with the spirit when the spirit flow is on, and the spirit will be mechanically carried along by the oil when the oil flow is on, and, further, that the impure oil hanging about the porous substance will not be carried on by the general flow of the oil, so that the apparatus is by no means so methodical as it looks.

That the apparatus was open to some such objections as I have named seems probable, for in the following year, 1887, Bang and Ruffin took out another patent for an apparatus shown in Fig. 5, which is, I believe, the apparatus now used by their company at their works near Paris. In this apparatus all attempt at methodical treatment is abandoned. The dilute alcohol to be treated is put into a large vat A, and the hydrocarbon oil is pumped in by the pump P through the perforated pipe T, thus reverting practically to the original arrangement. The bubbles of oil rise by gravity to the top of the vat, and the oil which collects runs off through the parachute pipe H. The oil passes next to the vessel B, where "the oil descending on one side of the partition and ascending on the other deposits in B some of the heavier impurities carried over by it," whatever that sentence may mean. From B it overflows into C, ascending in streams through a perforated pipe and a perforated floor, through water, to remove any alcohol mechanically carried over, and then through D, D, D, D, provided also with perforated pipes and perforated floors, and filled with pieces of glass, where it is treated with strong sulphuric acid. Then on to E, where it encounters a solution of soda (the marble business, I presume, not being found to answer), and finally into the reservoir F, from which it is pumped back to the vat A. During the operation the sulphuric acid is moved upwards successively from the lower to the upper vessels D, but it has to be bucketed up in jugs, an operation which is neither neat nor handy. I should mention that the dilute spirit in A is made alkaline in order to resinify any aldehyde that may be present.

One of the chief objections to this process is that it is very slow. Something like 48 hours at least is required for the purification of the alcohol. At the beginning the oil is largely contaminated with fusel oil, but as the operation goes on it takes out less and less, and yet has to go through the same process of regeneration. It is like washing out completely a voluminous precipitate, and then having to boil down all the endless wash waters. Every chemist knows what a ghastly operation this is. I say nothing of the bucketing up of the sulphuric acid, but after what I have said about perforated false bottoms, it may be doubted

whether the distribution in the vessels D, D, D, D, is very effective.

In 1887 Bowick attempted to meet these difficulties by the construction of an apparatus which should be perfectly methodical in its action, and yet free from the objections to Bang and Ruffin's, 1886. His apparatus is based on the principle that if we take a fairly intimate mixture of dilute alcohol (or water) and hydrocarbon oil, and pour it on a filter wetted with oil, it is only the oil which passes through, leaving the dilute alcohol behind, while if the mixture is poured on to a filter previously wetted with dilute alcohol (or water) only the dilute alcohol will pass through, leaving the oil behind.

The arrangement is shown *diagrammatically* in Fig. 6. It consists of a series of cylinders, all precisely similar, connected together as shown. Each is provided at the top and at the bottom with a filter E, E'. These are supported by perforated metal plates, not for the purpose of distribution, but simply as supports. These vessels are filled about one-third with water or purified dilute alcohol (this wets the lower filter), and are then filled up with the hydrocarbon oil (this greases the top filter). The outlet cock D for the oil being closed, and the outlet cock F for the spirit being open, the dilute spirit is pumped in, by means of the pump S, through the roses A, placed horizontally, so as to give a rotary motion to the contents of the cylinder. Under these circumstances a species of emulsion is formed, which, being somewhat heavier than the oil, slowly descends until it reaches the bottom filter, where it is separated into the dilute alcohol, which passes through, and the oil, which rises to rejoin the layer of oil above. The same process takes place in each successive cylinder, and thus the spirit, coming in contact with oil always purer and purer, issues in a constant stream at F, deprived of all those impurities which the oil is capable of absorbing. As in Bang and Ruffin's 1886 proposal, it is necessary occasionally to displace the oil in the opposite direction. To do this the spirit pump is stopped, and the oil pump O set to work, the cock F being closed and the cock D open. The upper filters then come into play, and prevent any of the dilute alcohol being carried over mechanically by the oil. In order to make sure that the two liquids shall only travel in the prescribed direction, back-pressure valves, C, C', C'', are introduced. The oil is regenerated by simply blowing through it a current of steam, which carries off the whole of the fusel oil. This can be condensed and collected. As there is a strong demand for fusel oil at a price higher than the price of spirit, this is a decided advantage over the destruction of the fusel oil by means of sulphuric acid.

The oil employed is one which boils at or about the boiling point of mercury, so that there is no danger of any being vaporised with the spirit. It is perfectly destitute of taste or smell. It dissolves fusel oil with the greatest ease, and is, therefore, well fitted for its removal; and I believe that this process is a good one for the removal of fusel oil.

The advantage of Bowick's apparatus is that it permits a far greater subdivision of the oil, and therefore more intimate contact without any danger of the oil being mechanically carried along in the stream of spirit, or the spirit in that of the oil. It is, moreover, perfectly methodical and continuous in its action, and in consequence, the oil is always charged to the fullest extent with impurities, and there is no oil weak in impurities to treat, as in the latest Bang and Ruffin. Even with the Bowick apparatus it is not advisable to go too far in the subdivision. If the particles of oil are more minute than the pores of the paper they will go through; just as milk does. But if the pressure and the size of the openings in the roses are properly adjusted, very great subdivision may be attained, with complete separation by the filters.

Whatever apparatus is used, the result in the end must be the same. If you go on treating dilute spirit with hydrocarbon oil long enough, you will end by removing all that the hydrocarbons will remove. It is simply a question of employing an apparatus which will do it, most economically and in the shortest time.

As to the efficiency of the hydrocarbon process, it is clear that if the impurities are more soluble in the hydrocarbon

than in the dilute spirit, they will be removed. If more soluble in the spirit than in the oil they will not be.

Now, aldehyde is not an unfrequent constituent of crude spirit. All the patentees claim more or less that the hydrocarbon process gets out the aldehyde. But aldehyde is perfectly insoluble in the hydrocarbon oil, while it is soluble in all proportions in water and alcohol. Therefore the hydrocarbon process cannot remove it. Bang and Rutlin make their dilute spirit alkaline in order to resinify the aldehyde, but the resinification is accompanied by the formation of some volatile body of very pungent smell, so that the remedy is as bad as the disease.

As the alcohol is employed in a dilute form, it is necessary in any case to pass it through a rectifying still in order to remove the water. As the aldehyde is very volatile it comes over first, and that will be the best way of getting rid of it.

Speaking generally, I think the hydrocarbon process is a distinct advance on the charcoal process. It removes the fusel oil most effectually. Owing to the presence of aldehyde, and some very volatile ethers possibly, not removed by the hydrocarbon, there will still be some "heads" to reject, but spirit purified by the hydrocarbon process is almost entirely free from tails. Whether it will be possible to devise any process which shall be capable of removing every possible impurity from commercial alcohol without the aid of the rectifying still, I may be permitted to doubt.

DISCUSSION.

Mr. B. E. R. NEWLANDS said that he had devoted considerable time and attention to the two processes described by Dr. Squire. He had had an opportunity of seeing the Bowick process at work at Vauxhall, and he had recently spent a week at Paris in examining the Bang and Rutlin process. The Bowick process was being worked on only a small scale; but by the Bang and Rutlin method some 10,000 litres of alcohol were being treated daily, and the process worked well. He had taken samples at various stages of the process, and having examined them carefully had come to the conclusion that the Bang and Rutlin process produced alcohol quite equal to the best charcoal spirit. It was true that petroleum had little or no solvent action on aldehyde; but by boiling the alcohol and passing the vapours through a condenser surrounded by water at such a temperature that while the alcohol was condensed the aldehyde passed over, the head of the impurities was caught before commencing the petroleum treatment. A full consideration of the matter had convinced him that petroleum by itself would be of but little use. It must be worked concurrently with some other process, as at Paris, for removing the aldehyde and ethers, and at present he knew of no method other than distillation suitable for that purpose. If, however, the Excise authorities in this country would allow petroleum to be employed on a commercial scale in the distillery these processes might probably have a future before them, seeing that for purifying certain kinds of spirit, such as those produced from beet molasses, they would appear to be specially suitable. However, until the Excise authorities allowed greater freedom of action it would, he feared, be impossible to carry out any petroleum process in England in a distillery. In the meantime, so far as this country was concerned, the processes would have to remain in their present experimental position.

MR. E. C. C. STANFORD IN THE CHAIR.

REFRACTORY GOLD ORES.

BY J. HOLMS POLLOCK, B.Sc., UNIVERSITY OF GLASGOW.

In dealing with gold quartz the first point of interest is the character of the quartz, as this has a very important bearing on the best manner of treatment. Quartz can be more or less divided into three groups according to its behaviour on treatment, viz., free-milling; float, fine, or rusty; and refractory quartz. In free-milling quartz the gold exists in a coarse granular condition scattered throughout the body of the quartz, which generally consists of pretty pure silica with little oxide of iron or sulphides, though the presence of these in moderate quantity is not necessarily detrimental so long as the gold is in a coarse or granular state. With these the miner has no difficulty, all he has to do is to crush and amalgamate in the ordinary manner with the stamp battery, and collect the gold by riffles and amalgamated copper plates, a very large proportion of the gold present being readily secured. This is the good old style of quartz that used to be obtained plentifully in Victoria and California. Of this class of ore I have few specimens, as it is of little interest to me; for when people can treat their ores without difficulty, they do not take the trouble to send samples to be tested by new processes. However, I have here a specimen from Queensland in which you will see the little specks of gold without difficulty.

In rusty, float-, or fine-gold quartzes, though there is not much pyrites or other sulphides present, there is much loss in working, for the gold is in a finely divided state and disseminated through the quartz. When these ores are subjected to the ordinary process of crushing and amalgamation, the loss of gold is very great indeed, the fine gold being carried away by the water along with the quartz, and going over in the tailings. In some cases, when the gold is very fine, much of it does not even remain in the tailings, but passes away in the sludges, and is irreparably lost. From investigation, I am inclined to think that these ores were originally of the refractory type, the iron being in the form of sulphide, with the gold, as it were, alloyed with it,

or perhaps the gold itself existing as sulphide, and that subsequently by percolation of water the pyrites was weathered and converted into hydrated oxide of iron, leaving the gold in an excessively fine state of division throughout this oxide. If you crush these quartzes, and attempt to concentrate them by washing, you find that the iron oxide, because of its softness, crushes very finely, and then the water carries this fine oxide over; if the oxide is allowed to deposit and then assayed, it gives more gold than the heavy portions remaining behind. Then again, these quartzes are usually vesicular, and often contain ferrous oxide, and lastly the veins composed of them usually pass into pyrites quartz at greater depth, all which points to the supposition that they were formerly of the refractory type. Of course no exact line can be drawn between these float or rusty ores and the free-milling or coarse gold quartzes, for the float gold quartzes usually contain a considerable proportion of the gold coarse enough to be saved by the ordinary methods; and as miners never like to talk of the gold they *do not get*, they very much prefer to call these "too free-milling" ores if they can get any profitable return. The importance of this may be judged when I say that in the Transvaal, where almost all the ores at present worked are of this type, the gold lost is usually as much as that saved, and large quantities of valuable tailings have now accumulated. At the Sheba Mine, the tailings assay about $2\frac{1}{2}$ oz. of gold per ton, while at the Wemmer and Jumper Mines there are tailings assaying respectively 3 oz. and 4 oz. per ton, while of tailings of about 1 oz. there is any quantity. In New Zealand the state of affairs is even worse, or better for those who can extract the gold. There the loss owing to float or fine gold is so great that in many cases rich ores will not pay the working. I know of one ore which assayed 5 oz. per ton, but when treated in London by amalgamation, it only yielded 1 oz., and I may add that in this case the gold was so excessively fine that little of it remained in the tailings, the bulk of it going off in the sludges, and being thus irreparably lost; but when this sample was treated by hydraulic chlorination it yielded $4\frac{3}{4}$ oz. of gold per ton. Another point of interest in New Zealand ores, more particularly in the Auckland district, is that they often contain a large proportion of silver as well as gold, which makes the working of these ores exceptionally profitable. It is quite possible that the excessively "floaty" character of the gold may in no small degree be caused by this silver, for, as is well known, silver is very difficult to concentrate, and were the gold associated with it, one could easily understand how it might be carried away, besides which the sulphide or chloride of silver would envelop the gold, and prevent its amalgamation. In the United States of America, British Columbia, and elsewhere, there is also much loss owing to fine gold.

Next we have the truly refractory quartz, which is quartz associated with much iron pyrites or other sulphides, but usually with iron or arsenical pyrites. Many of these cannot be worked at all by amalgamation, for not only does amalgamation fail to extract the gold, but the mercury is itself fouled and carried away. These refractory ores are often solid pyrites, and contain no amalgamable gold whatever; at other times they contain a certain proportion of the gold in a coarse and amalgamable form, and I have found this to be most frequently the case when they are not solid pyrites, but quartzes with a considerable proportion of pyrites present. I have seldom found ores of this class to contain much float or fine gold, and this has a very important bearing on their economical working, for these ores, which are an admixture of quartz and pyrites, can be crushed and concentrated before treatment with little or no loss, practically the whole of the gold, both coarse and that contained in the pyrites, being found in the concentrates. In this way the cost of working is greatly reduced, for in place of having to chlorinate the whole bulk of the stone, you have only to treat the concentrates obtained. It is ore of this class which is to be found in Wales, and owing to the cheapness of operating in this way, comparatively poor ores may, in my opinion, be made to yield a handsome profit. I have here a specimen of rock impregnated with pyrites, which assays only 3 dwt. of gold per ton, but by crushing and concentrating by jigging, 10 tons of ore yield

1 ton of concentrates, assaying $1\frac{1}{2}$ oz. of gold per ton, besides copper and silver, and if desired, by finer crushing and more careful concentration, 30 tons of stone may be made to yield 1 ton of concentrates, assaying about 3 oz. of gold per ton, besides copper and silver, and these concentrates may then readily be worked by hydraulic chlorination, which secures practically the whole of the gold, silver, and copper present. With this system of treatment I shall not be surprised if Wales becomes a very profitable field for gold-mining enterprise, and certainly the discovery of gold in Wales offers great facilities for thoroughly testing new methods of treating refractory ores.

In Queensland there are large quantities of rich auriferous pyrites which also contain considerable quantities of copper easily extracted along with the gold. I have here two specimens, the one from Ravenswood Mine containing 2 oz. gold, 2 oz. 5 dwt. silver per ton, and 4 per cent. copper; the other, from Bethanga Mine, containing 2 oz. 14 dwt. gold, 1 oz. 10 dwt. silver per ton, and 3.1 per cent. copper. In the Transvaal, as I have already explained, the ores at present worked are for the most part of the float gold character, but there also vast quantities of auriferous iron and arsenical pyrites which have not as yet been touched, except in a few cases, for the very good reason that the gold cannot be extracted by amalgamation, and mines of this class which have been opened up have in almost every case been subsequently abandoned, though I know of one that is still lingering in a precarious condition. There they have arsenical pyrites assaying about 2 oz. of gold per ton, but they cannot get enough out to make it pay, extracting as they do only about 6 or 7 dwt.

To treat ores by hydraulic chlorination the ore is first crushed to about the fineness of fine sand, that is, to a fineness which would pass through wire gauze of about 25 mesh to the linear inch, and it is very desirable in crushing the quartz to use machinery which will produce as little fine dust as possible, otherwise the filter is apt to get choked in the subsequent operations. After crushing, the ore is when necessary roasted, the object of which is to remove the sulphur and convert the iron into anhydrous ferric oxide, in which state it is not acted on by chlorine, and to leave the ore in a porous or sponge-like condition. With float gold quartzes it is often quite unnecessary to roast. I have here a number that will chlorinate just as well without roasting, viz., Sheba tailings, Reliance reef quartz, Dutch Guiana quartz, and concentrated river sand from Assam. On the other hand it is often desirable to roast float gold ores though they may contain no pyrites, for if the iron oxide be hydrated the chlorine acts on it, and either you must add more chlorine or roast, whichever is the most economical under the circumstances. With pyrites ores roasting is at all times absolutely indispensable, and I venture to assert that there is no other chemical process that could successfully deal with these ores without roasting. When copper, lead, zinc, &c., are present in the pyrites, a small proportion of salt is added in the roasting so as to chlorinate these metals in the furnace, and thus prevent them consuming chlorine in the subsequent operation, for though anhydrous ferric oxide is not affected by chlorine the oxides of these metals are readily dissolved. For the purpose of roasting any suitable furnace may be used, provided always that the ore is kept well mixed and the heat is regular and does not rise much above a dull red. Perhaps the revolving furnace is the best for economical working, but those used by the Tharsis Copper Company for calcining copper ores are perfectly suitable.

After the ore is properly roasted it is allowed to cool, or partially cool, and placed in revolving cylinders in charges of about $1\frac{1}{2}$ tons at a time with about 1 per cent. of bleaching powder, and $1\frac{1}{2}$ per cent. of bisulphate of soda, these being added the one before the other and after the ore to prevent the liberation of chlorine before revolving the cylinder. As soon as the ore and reagents are placed in the cylinder the cover is screwed over the charging aperture and the valve on the hydraulic supply pipe opened, when water rushes in from the accumulator or pump, the air escaping from the cylinder by a valve placed on the top for that purpose. When the cylinder is full the air escape is closed and the cylinder revolved, the accumulator or pump exerting a

steady pressure throughout the whole operation. The hydraulic pipe does not interfere with the rotation of the cylinder as it passes through the centre of rotation, to one end of which it is connected by a packing box that keeps the pipe perfectly tight, but leaves the cylinder free to revolve. Inside the hydraulic supply pipe and immediately beyond the packing box is placed an automatic rubber valve which is made like a cone slit at the top and placed pointing into the cylinder; through this the water can enter freely, but it prevents ore and solution from finding its way out of the cylinder into the pipe. The object of removing the air from the cylinder is that any air present acts detrimentally in absorbing part of the chlorine, and this chlorine not being in solution is utterly valueless for the purpose of chlorinating gold. It is quite a mistake to think that by pumping more air into the cylinder the amount of this useless excess of chlorine would be in any way diminished, for, as is well known, by Dalton's law one gas is a vacuum to every other gas. If you have a given volume of air with a quantity of chlorine diffused through it, you might pump in more air until you burst the containing vessel, but you would never liquefy a single drop of that useless chlorine or drive it into solution, for though the liquefying point of chlorine is about 60 lb. per square inch, it must be remembered that that only means that chlorine liquefies when the pressure of its own vapour is 60 lb. and not when other gases with which it happens to be mixed are at 60 lb. By use of hydraulic pressure the whole of the chlorine present is retained in solution, and the high pressure rapidly forces this strong chlorinating liquid into the pores of the ore. When the chlorination is completed the hydraulic pressure is shut off, the excess of chlorine blown out, and the ore and solution discharged on a suitable filter, the liquid being rapidly filtered through and delivered into tanks by means similar to those practised for many years in most gold and silver works in America, and fully described in Egleston's book on gold and many earlier publications; or if preferred the filtration may be accelerated by means of a vacuum pump, as is done in many alkali works in this country (first patented by Spencer in U.S.A., 4th June 1867). For practical working, however, I prefer the American plan of using a steam ejector. The gold is then precipitated in the tanks in which the solution is collected, by means of ferrous sulphate or other suitable precipitant. After settling for 12 hours the clear liquor is run off through charcoal filters, which serve to arrest any gold that has not completely settled; then more liquors can be run into the tanks, and these in their turn precipitated on the top of the last, and so on until sufficient precipitate has accumulated, when it is collected, dried, and fused. In like manner the charcoal filters are occasionally cleaned out, the charcoal being burned and the contained gold collected.

When ores contain copper, silver, lead, zinc, or lime; or if you have complex ores partly float and partly coarse gold, or partly pyrites gold and partly coarse gold, various modifications are introduced for the most economical treatment of these, but time will not permit my entering into detail. I may add that recently I have made a number of improvements in the process which greatly add to the ease in working, and which make our machinery cheaper, lighter, and if possible more simple, and I have now made the process applicable to the few ores with which I had formerly some difficulty. Needless to relate these improvements are or will be secured by patents.

I think I am within the mark in stating that at the present moment I can treat almost any ore in existence at a cost of about 6s. 6d. per ton in Glasgow, guaranteeing an extraction of 95 per cent. of the gold present.

DISCUSSION.

MR. ELLIS said he would like to ask Mr. Pollok how much chlorine there was in the liquor after it came away from the cylinder; what amount of sulphate of iron was used for precipitation, and what quantity of ore was put into the cylinder?

MR. ROTTENBURG asked what was the proportion of liquid to ore in the cylinder; what time the filtration took; what weight of ore had been practically treated; and what would be the cost of roasting the ore in the Transvaal?

MR. RÖDGER said that Mr. Pollok had stated that 6s. 6d. per ton of ore was the total cost of treatment. That, he presumed, referred to quartz ores only, for it would be impossible to roast refractory ores for that sum.

MR. PLAYFAIR said the ores that derived their value from the gold were mostly free-milling ores, and there was no difficulty in treating these, but it was different with the refractory ores, because they sometimes contained a larger value of silver than gold. He would like Mr. Pollok to have gone further into that matter in his paper. Would Mr. Pollok say if he had ever tried manganese ores?

THE CHAIRMAN said that the next generation would probably see a large development in wet processes, not only for gold, but other precious metals. He could not understand how it was possible to extract the gold from the ore properly by amalgamation.

MR. POLLOK, in reply to Mr. Ellis, said that roughly speaking there was about half the chlorine left in the liquor after it came from the cylinder, that about 1 per cent. of sulphate of iron was used for precipitation, and that about $1\frac{1}{4}$ tons of ore were put into the cylinder at a time. In reply to Mr. Rottenburg he stated that there were about equal volumes of liquid and of solid in the cylinder. The total amount of liquor used for each charge, including washing, was about 40 cubic feet, and the volume of loose ore thrown into the cylinder was 25 to 30 cubic feet. The time for filtration, if the ore was not too finely crushed, was about half an hour. About $1\frac{1}{2}$ cwt. had been practically treated, and of a heavy ore about 2 cwt. at a single charge. The cost of treating the ore in the Transvaal he thought would be from 20s. to 24s. per ton.

As to the charge of 6s. 6d. per ton for treatment in Glasgow, one point had to be taken into consideration in that connexion. There the sulphur could be sold, but abroad the sulphur could be burnt off in the open air without any serious trouble from the authorities, and accordingly they were roasted in open hearths at a very low cost. Replying to Mr. Playfair, he said he had used the usual processes for the extraction of silver, and had not had an opportunity of trying manganese ores. He had not found it to be the case that refractory ores generally contained more value in silver than in gold.

A SHORT ACCOUNT OF THE OPIUM INDUSTRY IN THE N.W. PROVINCES AND OUDH.

BY T. A. WEIR, M.B.

AT the request of the Secretary I have compiled, for the information of the Section, the following notes, the greater part of the material of which already exists on record, for the most part, however, in the official publications of the Governments of Bengal and of India, which are not perhaps within reach of many in this country.

The opium poppy is a native of Asia Minor, but having been so long and generally cultivated in Europe and parts of Asia, it is now naturalised less or more in many different countries. The precise date of its introduction to India is unknown, but it can be traced as far back as the 16th century, during the latter half of which the produce of the opium monopoly in the sarkars of Allahabad and in Ghazipur was 1,000 chests, according to the A'in Akhbar of Abul Fazl. It had attained considerable importance by 1786, at which time Lord Cornwallis wrote a minute respecting the best method of deriving a revenue from opium. It has now been long extensively cultivated in the Upper Gangetic plain, in Behar, Bundelkhand, and Malwa. "The area under poppy cultivation in the N.W. Provinces and Oudh is scattered over 38 of the 49 revenue districts in these provinces, and occupies more than $\frac{1}{4}$ million acres, and necessitates the employment of no less than 2 $\frac{1}{2}$ millions persons in the fields." For the Chinese market the opium

of the Behar and Benares agencies is commercially the best, as being the most approved by the Chinese, although *officially* it is inferior to the Smyrna drug.

The cultivation of opium in India in British territory is a Government monopoly, existing for the benefit of the Imperial revenue. The Opium Department is for convenience administered, under the Lieutenant-Governor of Bengal, by the Board of Revenue of the Lower Provinces. Subordinate to the Board are the two opium agents, each of whom is in charge of one of the two opium agencies. One of these is the Behar agency, with its headquarters at Patna, and situated entirely in the Lower Provinces. The other is the Benares opium agency, situated in the N.W. Provinces and Oudh, and having its headquarters at Ghazipur, on the Ganges, about 40 miles from Benares. In each agency there are under the agent two sets of officials, the district officers concerned with the production of the raw material, and the factory staff occupied in its manufacture.

The system of cultivation at present in force in British territory is briefly as follows:—No poppy is allowed to be grown save with the permission of Government. Government grants this permission to suitable cultivators on condition that only a certain definitely agreed-on area of land shall be sown by each with poppy, and that the entire produce shall be made over at the proper time to the agents of Government in exchange for its value in cash calculated at the rate (at present) of Rs. 5 per ser of 70³ consistence. (70³ consistence opium is opium of which 100 grms., when dried at 100° C., yield 70 grms. residue. Opium of this consistence is called standard opium.) Permits or licenses to grow poppy are issued in the period from August to October, at which time the district officers meet the would-be cultivators or their agents and settle more or less directly with each the area he is to be allowed to cultivate. The experience of many seasons, as recorded in the books of his office for each locality, enables a district officer to estimate very closely the average quantity of standard opium that the particular area licensed to any cultivator is likely to produce. In this way the district officer is able to keep within the limits of the quantity his district has been called on to supply, which quantity in turn is based on the indent sent down by Government to the agent, and by him apportioned among the districts under his charge. At the time of settlement the district officer makes to the cultivator a cash advance of a certain percentage of the value of the out-turn of standard opium that the area he has undertaken to cultivate is estimated to produce. For such advances, and for similar advances towards the purchase of bullocks, the sinking of wells, &c., and aggregating over 200 lakhs of rupees (nominal two million pounds sterling) per annum, no interest is charged by Government, the cultivator enjoying the use of the money free. The advances are in due course recovered in the shape mainly of produce, the balances being paid up in cash, and outstanding of any size are little known.

Having settled with the district officer, and been licensed to sow a certain area, the cultivator returns home and prepares his land, and makes other necessary arrangements, and in due course, about November, he commences to sow his seed. During the growth of the plant, the industrious cultivator takes care to attend to its proper tillage, watering it at the proper times, and keeping the ground free from weeds.

During this season the district officer with his staff goes on tour throughout the area under his charge—which may measure many hundred square miles—in order to measure the ground cultivated by each licensee for the purpose of seeing that he has sown up to his engagements (on which his advances were calculated), and not in excess of his engagements (as this would throw out the arrangements for complying exactly with the indent sent down by Government); to see that the cultivation is being carried on in a proper manner (the plant being watered as required, and the soil kept clear of weeds), and that no other crops are being simultaneously cultivated in the poppy field; to give, if necessary, a further cash advance on account of the value of the estimated out-turn; to see that no illicit poppy cultivation is being practised (which would lead to

smuggling, and to the defrauding of the Excise revenue); and to report, periodically, to the agent on the general prospects of the crop.

About the beginning of February the plants begin to flower. At this time is begun in certain districts the preparation of "leaf." "Leaf" is the technical name for the material used at the factory to form the shell of the opium cake in course of provision for the China market. About the close of the third day of the flower's expansion the petals are in such a stage of maturity that they are ready to drop off the top of the seed-vessel at a touch; at this stage the cultivators go through the fields in the afternoon, and collect the petals or carry them home. In the evening, after she has basked her husband's hammock, the cultivator's wife takes two or three handfuls of the petals and throws them on the top of the hot griddle-iron, and as the gummy juice of the petals exudes by the heat, she presses the petals down by a damp cloth which she skilfully manipulates, until what with the steam from the cloth, and the gum in the leaves, the petals become agglutinated, and ultimately take the pancake-like form of the so-called "leaf." The leaves are carefully dried, and are in due course brought by the cultivator to the district officer, who receives them on behalf of Government, and pays for them according to their quality, at from Rs. 10 to 5 a per maund (of 82½ lb.), and forwards them to the factory at the headquarters of the agency for disposal.

The annual consumption of "leaf" in the preparation of the shells of the provision of opium for the China market is very large—amounting to from 16 to 20,000 maunds—representing the petals of over 5,000 million flowers according to Scott's calculations.

In the course of from 7 to 10 days from the fall of the flower leaves, the capsules are sufficiently mature for the extraction of the drug, becoming plump and firm, and coated with a fine whitish bloom.

The incisions are now commenced, and are carried on regularly every third day, and according to the condition of the plant, and the time of the collection, the number of lancings required to extract all the juice varies from one to five or six, and perhaps seven in isolated cases. The lancing is carried on in the afternoon, and consists of three or four vertical incisions performed at one operation by three or four primitive lancets tied together with cotton thread. The juice exudes slowly, and is milky white at first, the outer part of the tear gradually changing to a pinky salmon colour. Next morning the tears that have exuded are scraped off by an iron trowel-shaped scraper and put into a metal dish, from which at the cultivator's house they are transferred to unglazed earthen vessels set afloat to allow excess of watery matter and pasewa to drain off. The aggregate of the drug belonging to a cultivator is kept in a shady place in his house, and carefully treated so as not to injure the grain, but to allow the consistence to rise evenly until it has reached the desired degree. The opium is then brought to the district officer at the appointed time and place, and he receives it over by weight on behalf of Government, and transmits it to the factory in jars containing one maund (82½ lb.) each, paying to the cultivator a further advance on its value according to his estimate of its assay. The annual amount of opium delivered in the two agencies amounts to perhaps 107,000 maunds at 70³ (equal to about 3,900 tons, and for which the cultivator would receive Rs. 2,14,00,000, nominally 2½ million pounds sterling).

After the collection of the opium has ceased the plants are allowed to remain standing in the fields till the capsules are quite ripe; these are then collected, and the plant leaves when dry are, in certain districts, gathered and sent into the factory under the name of *trash*, to be used as dunnage in packing the provision opium for China. Trash is paid for in the Benares agency at about 10 annas per maund. The annual out-turn of trash in the two agencies is more than 28,000 maunds.

The opium on arrival at the factory is, after weighing, examined jar by jar by the opium examiner, who certifies to its quality and purity. It then has its consistence determined for each jar by assay on the steam table, and

according to its consistence it is stored away in one or other of the extensive ranging store vats in the malkhana or storehouse, some of which hold 3,000 maunds. The final payments to the cultivators are made according to the value of the opium as determined by its consistence on assay at the factory.

When a sufficient quantity of suitable opium has been received into the factory, the manufacture of the provision of opium for the China market is commenced. The provision is caked at the consistence of 70°, to this end quantities of opium of consistencies above and below 70° are alligated or mixed together in certain proportions so that the mean consistence of the mixture may fall within the limits allowed. Before issue from the caking vats the opium in them is assayed for consistence to ensure that it does not fall below the caking standard laid down by Government.

For each "cake" there are served out the equivalent of a certain weight of standard opium for the central mass, together with a certain measure of "*lewa*," the equivalent of a fixed weight of standard opium. *Lewa* is a paste made of opium broken up in water, and is of 52·5° consistence. For each cake is also issued a certain weight of leaf, which is previously damped to make it flexible and non-friable.

In a hemispherical brass cup of about 6 in. diameter, the cakemaker pastes layer after layer of pieces of leaf which he gums together with *lewa* until the thickness of the hemisphere of shell in the cup is $\frac{1}{2}$ in., and over the edges of the mould he allows the free ends of the pieces of leaf in the cup to hang. The opium is then deposited in the centre of the hemisphere of shell in the cup, and over it the overhanging leaves are brought and carefully imbricated and pasted down with *lewa*, and bound together by fresh portions of leaf, and finally over all one of the finest leaves is pasted on and a complete sphere results. This is turned out of the cup and covered half-way up with "trash," which prevents its sticking to the inside of the porous earthenware cup into which the cake is now put. The cup and cake are put on a shelf in a well-ventilated warehouse. Caking goes on from May till July at the rate of about 20,000 cakes per diem. The cakes remain on the racks till they are fit for packing, and each cake is periodically turned about in the cup so that it shall dry regularly and evenly, and preserve its spherical shape.

Packing begins about the middle of November. Previous to the commencement of the season's packing the chief civil officer or magistrate of the district visits the factory and selects at random out of the whole stock of provision in the factory six cakes for analysis; two are retained at the factory, two sent to the sister factory, and two go to the chemical examiner to Government at Calcutta. The results of the analysis of each of these three sets of two cakes (in terms of their morphia, narcotine, and smokeable extract) are put on the table at the first sale of the season's opium, for the information of the merchants.

Packing is carried on in fine weather only, and is not practicable in damp, cloudy, or rainy weather. 20,000 cakes are packed daily in 500 chests, 40 cakes in a chest, the damage used being the "trash" already described. 500 chests a day are daily despatched from the factory en route for Calcutta, where they are stored in large warehouses under the charge of the Board of Revenue, by whom a certain number are exposed for sale each month on account of the Imperial Government.

The opium intended for Indian consumption is not made up into balls of 70° consistence; it is exposed in the sun in shallow trays until it has become inspissated to a consistence of 90°, at which point it is melted into cubical cakes of 1 ser, each of which is smeared with poppy oil and packed in two layers of bamboo paper. The cakes are then packed in sixties in mango-wood chests, which are distributed as required to the different treasuries of the N. W. Provinces and Oudh and Central Provinces.

Opium, which on examination at either factory is found to be adulterated or otherwise unfit for manufacture, is confiscated, and the morphia and codeia in it are recovered in the laboratory department of the Ghazipur factory

Narcotine used also to be recovered; the demand for it has, however, now almost entirely ceased, and it is no longer prepared at Ghazipur.

"The cultivation of the poppy is popular amongst our cultivators . . . the certainty of receiving a fixed price for their opium, the payment of advances without interest at periods at which the Asámis are generally hard pressed for funds; the obtaining high prices both for the poppy petals and leaves; the getting advances free of interest for wells and frequently for purchase of bullocks; and the remission of all the advances outstanding if their crop has been destroyed by hail: these advantages and the large profits derived from opium attach the Asámis to the cultivation and make it popular. Hindoos of all castes, from Brahmans down to Chamars, and Mahomedans, too, cultivate poppy, but the Koeri caste are our best cultivators."—(Turnbull.)

In one year, for an actual cultivation area of 899,287 highas (562,054 imp. acres), cultivated by 1,448,508 Asámis, the out-turn of opium at 70° consistence was 107,577 maunds (3,952 tons), for which were paid to the cultivators in hard cash Rs. 2,15,15,400 (2½ million pounds sterling nominal), besides which 19,872 maunds of leaf and 28,773 maunds of trash were supplied and paid for.

In the same year there were turned out (from confiscated useless opium)—

DISCUSSION.

The CHAIRMAN said he would be obliged if Dr. Weir would tell the meeting: What was the amount of morphia in the opium? Was the leaf that had been shown round—and which he presumed was a collection of poppy petals—used for any other purpose than covering the opium? Did the said leaf contain any morphia? A curious fact he had noticed was that the red poppy which was so common in the fields in this country, and which bore such a strong smell of opium, did not contain morphia. Why did a Chinaman prefer to smoke opium that contained little or no morphia?

Dr. WEIR, in reply to the Chairman, said that the amount of morphia in the opium was from 2 to 5 per cent.; that the leaf referred to was not used for any other purpose than covering the opium, and that it did not contain any morphia. The Chinaman preferred to smoke opium that contained little or no morphia because if not used to excess it would do him no harm.

Obituary.

Dr. JOHN PERCY, F.R.S.

SCIENTIFIC metallurgy in this country has lost its most distinguished representative by the death of Dr. Percy, which occurred at his house in Bayswater on Wednesday, June 19. Born in 1817, the son of a Nottingham solicitor, John Percy was placed at an early age in the medical school of the University of Edinburgh, where he took his degree of M.D. at the age of twenty-one. At Edinburgh he was the pupil of Sir Charles Bell, and a fellow-student with Edward Forbes. Dr. Percy also studied in the medical schools of Paris, and while in France undertook a botanical tour in the Pyrenees. He established himself in practice in Birmingham, where he became physician to the Queen's Hospital. While there he carried on some remarkable researches on the effect of alcohol on the animal economy, and in 1845 read before the British Association some "Contributions to the Chemistry of Diabetes." His residence in Birmingham led him to

take much interest in the chemical principles involved in metallurgical operations; and when the Government School of Mines was established in 1851, De la Beche selected Percy for the post of lecturer on metallurgy, a position which he held for twenty-eight years. Abandoning the practice of medicine, he settled in London, and devoted himself to scientific research, taking special interest in the early development of photography. His great object, however, seems to have been the production of an exhaustive treatise on metallurgy, and after years spent in the accumulation of material, his first volume was given to the world in 1861. This dealt mainly with the subjects of fuel, copper, and zinc. It was followed in 1861 by a voluminous treatise on iron and steel, and in due course other volumes appeared, dealing more or less completely with lead, silver, and gold. But this great work—the worthy object of an active life—was destined to remain incomplete, and after his retirement from the Royal School of Mines in 1879 its completion became practically impossible. So widely, however, was its value recognised, that the successive volumes as they appeared were translated into both French and German. In 1877 the Iron and Steel Institute recognised Dr. Percy's services to metallurgy by the award of the Bessemer medal; and only shortly before his death he held the Presidency of this Institute, and, notwithstanding his failing health, discharged the duties of the chair with characteristic ability. Up to the time of his death he was superintendent of ventilation in the Houses of Parliament, a position which gave him an extensive acquaintance among the members. Dr. Percy was a man of great force of character and versatility of tastes; a writer in command of a vigorous and pure style of English, a lecturer of power and popularity, and a teacher deeply respected by his students. For more than a quarter of a century Dr. Percy practically directed all the metallurgical teaching in this country, and nearly every assayer of scientific reputation had passed through his laboratory. It is understood that he leaves behind him large collections of metallurgical specimens, objects of natural history, and works of art. What will become of them we do not know, but they will not go to South Kensington.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Improvements in Boilers or Vessels Lined with Lead or other Acid-resisting Metal or Alloy. I. S. McDougall, J. T. McDougall, R. K. Hartley, and T. Sugden, Oldham. Eng. Pat. 7061, May 11, 1888. 8d.

This invention is concerned with improvements in the methods of securing the lining to the external shell of boilers and vessels to be lined with lead or other acid-resisting metal, so that no parts which can be injured by the acid are exposed to its action. For this purpose,

holes are made in the shell through which portions of the lining are passed. A cover, also of lead or other acid-resisting material, is placed over each hole, and is there secured to the shell by means of a disc or cover and suitable fastenings not exposed to the interior of the vessel. Four different modifications of the cover and mode of securing it are described, for details of which the drawing attached to the specification must be consulted. The improvements are protected by two claims.—E. S.

Improvements in Tubular Vacuum Pans. F. W. Scott. London. From A. Freitag, Amsterdam, Holland. Eng. Pat. 8064, June 1, 1888. 8d.

In the lower part of a vertical vacuum pan (preferably cylindrical) are arranged three chambers, of varying depths, one above the other. Each is provided with through-tubes fixed in tube-plates, forming the top and bottom walls of the chambers, which are united to the shell by angle-irons. The upper faces of the tube-plates slant down towards a large central passage for discharge (thus making the chambers annular in form). By means of pipes steam can be admitted, say from the bottom of the pan, to any or all of the chambers, or from one to the other, as may be desired. One side of each chamber is provided with an enclosed gauge-glass, or pane, by which the contents can be observed. In boiling sugar or syrup, this separate-heating system forms a strong coarse grain with a "low depth of juice." There are four claims.—E. S.

Apparatus for the Absorption of Gases. F. Carlisle, Franklin, and C. E. Hoffman, Jersey City, U.S.A. Eng. Pat. 293, January 8, 1889. 8d.

A CHAMBER contains a series of "conductors" which are slightly inclined, to promote the flow of the absorbing fluid along them. Each conductor is provided with a small open receptacle at its upper end, the receptacles of each series being placed alternately at the right- and left-hand ends, and the fluid is caused to flow along the under side ("as it is often seen to do on the under side of sloping roof beams when the roof leaks") to the lower end of the conductor, where it is directed by a lip into the receptacle of the next series, and so through the whole system. The fluid is supplied to the uppermost receptacles by a pipe from a tank, and finally drips from the lower ends of the last series of conductors into a tank. The gas to be absorbed enters at the bottom of the chamber, and by the arrangement of the conductors is divided into films, forced to pass between and beneath the whole series of conductors, and passing through a pipe in the upper part of the chamber can be again returned to it, to render its absorption by the fluid more complete. Five claims are made.—E. S.

Improvements in or connected with Filter Presses. J. A. Drake, Maidstone. Eng. Pat. 3681, March 1, 1889. 8d.

SAND or other filtering medium is placed in any number of horizontal metallic trays, each with a central boss, "and mounted on a hollow or fluted vertical spindle, so that each tray rests on the boss of the next one, and is kept apart according to the thickness of the filtering substance." Each tray is also provided with lateral slots for the reception of the liquid to be filtered, which is admitted through an inlet pipe in the base plate, whilst outlets in the boss allow the filtered liquid to flow down the spindle into an outlet pipe at the bottom of the press. The whole series of trays is enclosed in a casing which can be raised by suitable machinery when it is necessary to remove the filtered substance, which is done by rotating arms fixed on a vertical shaft at a distance apart corresponding to the space between the trays, and actuated by any mechanical means, the trays being at the same time caused to revolve slowly. The improvements are protected by three claims, and are illustrated by two drawings.—E. S.

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Rander Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	1d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " 2s. 4d.	1½d.
" 2s. 4d., " " 3s. 4d.	2d.

II.—FUEL, GAS, AND LIGHT.

On Smoke, its Formation, Prevention and Removal.
F. Fischer. *Zeits. f. angew. Chem.* 1889, 213—216.

THE burning of coal gives rise to more smoke than is the case with wood, turf or lignite, on account of the greater cooling effect of fresh additions of the fuel on the fire, and the solid particles composing the smoke diffusing less readily than a pure gas with the incoming air tend to escape unconsumed in their passage over the fire. Smoke seldom consists only of soot, but is usually contaminated with tarry matter which gives to the soot an unpleasant smell and a stickiness which causes it to adhere to the place on which it falls. On this account brown smoke can be a greater annoyance than the black variety. Of the numerous proposals for smoke prevention, those for removing the smoke by so-called soot-catchers or by washing the chimney gases can only lessen the annoyance to the neighbourhood, but do not prevent the loss of heat arising from soot deposits in the boiler flues. The introduction of air behind the fire is mostly prejudicial, as it only cools the mixed gases. A better plan is to conduct the smoky gases through a glowing hot brick grating. The more correct method of procedure is to prevent the formation of smoke by introducing the fuel continuously and moving it forward automatically at the same time that a movement of the firebars secures a passage for a regular supply of air. But the only perfect solution of the smoke question lies in the adoption of gas firing and gas engines, for which water-gas appears to be the only practical means at present.—G. H. B.

Thickening of Tar in the Hydraulic Main. H. Langen.
J. für Gasbeleucht. 32, 311—312.

THE author has previously drawn attention to the fact that the seal in the hydraulic main produces very considerable variations of pressure in the retort. The gas first drives out the liquor in the dip-pipe, and then forms a large bubble at the mouth of the pipe, the pressure in the retort being thereby increased. As soon as the bubble has attained a certain size it rises to the surface, forming, temporarily, an open channel between the retort and the hydraulic main, so that the pressure in the retort is again diminished; eventually the liquor again rises in the dip-pipe and the whole process is repeated. Distillation takes place, therefore, under a pressure which varies constantly between nil and a maximum, the latter being generally considerably greater than that due to the seal alone. Diminished production and partial decomposition of the heavier hydrocarbons result; the carbon thus produced is partly deposited as graphite on the walls of the retort and partly deposited in the ascension-pipe. During the rise of the liquor in the dip-pipe the gas either ceases to move or there is a backward movement favouring the accumulation of tar and graphite in the ascension-pipe; the area of the latter is consequently diminished, causing a further increase of pressure in the retort and greater decomposition of the heavier hydrocarbons. Some of the carbon also collects on the interior of the dip-pipe, diminishing the area and causing increased pressure. The remainder of the graphite mixes with the tar in the hydraulic main, making it much denser, and the heavier particles sink to the bottom, where they gradually accumulate and may ultimately reach the mouth of the dip-pipe.

In order to distribute the gas over a much larger surface of the liquor in the hydraulic main, the author recommends the following arrangement:—The dip-pipes are not cast in one piece with the bridge or H-pipe, but hang vertically in the hydraulic main on to the cover of which they are fastened with screw bolts. They are 25 cm. in internal diameter, 80 cm. in circumference, and 4.9 sq. dm. in area, whereas those usually employed at the present time are 12.5 cm. in internal diameter, equal to an area of 1.22 sq. dm. The equal-limbed bridge-pipe is provided with two self-closing eccentric pressure covers for cleaning purposes; it is, on the average, 15 cm. in internal diameter, the connecting pipe being generally even larger. By this

arrangement the pipes have all the same dip, and their area is increased four-fold, so that only one quarter of the gas produced comes into contact with a given surface of the liquor, and the surface of gas exposed to washing is double what it was before. The variation of pressure in the retort is in this way considerably diminished.

The thick tar can be readily removed during working by an arrangement which can be easily adapted to any existing hydraulic main. At one end of the hydraulic main the cover is removed and a small tank of the same shape as the main is screwed on with bolts. The tank is open above and is in direct connexion with the tar by means of an opening below. A screw is placed longitudinally at the bottom of the hydraulic main, and rests in thrust-blocks placed at opposite ends of the tank. Its axis projects into the tank and is there connected with a driving wheel by means of bevel-gearing. It is also provided with a chain and bucket arrangement, the number of the buckets being regulated according to circumstances, and in this way the tar is emptied into a small tank from which it runs directly by a large, inclined pipe to the tar well. The machinery is worked at stated intervals by hand, or continually by steam power, and the thick tar is thus removed as fast as it is formed, so that only liquor and light tar remain in the hydraulic main. With this arrangement the level in the main can be kept constant or the seal can be entirely taken off during carbonising.—F. S. K.

Heating Gas. L. Meyer. *Ber.* 22, 883—885.

To facilitate calculations of heat of combustion from the percentage volumes of a combustible gas, the author proposes the following method:—As the molecular weights of all gases in grams occupy 22.312 litres at 0° and 760 mm., suppose a gas contains the fraction x volume of a constituent. By multiplying the fraction x by the molecular heat of combustion of the gas, the number obtained is the heat of combustion of that gas in 22.312 litres of the mixture. If this be repeated for each constituent and the total divided by 22.312, the heat of combustion of 1 litre of the gas is obtained.—J. B. C.

The Development of the German Coke Industry. Dingl.
Polyt. J. 271, 444—452.

IN this paper various forms of modern coking ovens are considered as regards their efficiency and ease of working. W. Jicinsky (*Oester. Zeits. f. Berg und Hüttenwesen*, 1888, 530) describes in detail a coke furnace of the type first introduced by Hoffmann, in which the gases and air for combustion are subjected to a preliminary heating by means of a Siemens's regenerator. The oven in question is employed in the manufacture of tar and ammonia. Its dimensions are 10 × 1.6 × 0.5 m., and the charge is from 3,500—4,000 kilos. The interior of the furnace (Figs. 1 and 2) communicates by means of the tube g and valve a with the main V . The latter ends in a tube which leads to the reservoir for the tar and ammonia, about 1 m. underground. The circulation and exit of the gases take place through the tubes g , V , &c. to the ammonia holder, suction being applied by means of the exhauster E X (Figs. 5 and 6). The gases are then collected in a gasometer. A large portion of the gases is carried back from the gasometer to the oven, through an underground pipe which ends in the tubes g_1 and g_2 (Figs. 1 and 2) running parallel to the ground channel S_1 and S_2 , and on the same level. These two tubes are provided with as many gas-taps h_1 and h_2 as there are ovens. By this means the gas can be forced into the ground-channel. The ground-channel is divided in the middle by a partition b , which is perforated on one side next the furnace wall by as many holes c_1 and c_2 as there are vertical channels w_1 and w_2 in the side of the oven. All the vertical tubes w_1 and w_2 end in a common gas-main O . R_1 and R_2 are the two generators. They are 2 m. high and 1 m. broad, and are placed parallel to the gas-pipe g_1 and g_2 , and communicate by means of the openings d_1 and d_2 with the ground passages S_1 and S_2 . Each generator has as many openings d as there are ovens. They also communicate on one side with an air injector by

means of V , v_1 , and v_2 (Fig. 6), and on the other side with the coke-oven grate E . The generators are filled for two-thirds of their height with fire-bricks, so that a large surface is exposed to the gases. The injector Z (Figs. 4, 5, 6, and 7) forces a certain quantity of air alternately through each generator, so that the gases used for heating may be burnt. In the working of the oven the gases coming from the ammonia reservoir are passed only through the tube g_1 and from thence as much gas is allowed to enter the ground-channel S_1 through h_1 as is necessary for the heating of the oven. Simultaneously with these gases, hot air at 1,000° C. enters the ground-channel S_1 from the generator R_1 through the opening d_1 . At the high temperature the mixture of gases is completely burnt, and passes while burning through C , and the vertical passages w_1 into the gas-tube O (Figs. 1 and 2). From here the gases pass through w_2 and v_2 (Fig. 1) into the ground-channel S_2 , and from thence through the generator R_2 to the grate of the oven. During these operations the taps h_2 and the air tubes v_2 leading to the generator R_2 are closed. After about one hour the proper valves are opened and closed, and the gases made to circulate in the opposite direction, i.e. from R_2 to R_1 , instead of from R_1 to R_2 as before. If an oven is to be drawn, or allowed to cool, the tap a is closed, and the entrance of the gases into S_1 or S_2 can be prevented by closing h_1 , h_2 , and d_1 , d_2 . The process of coking is under perfect control, and can be hastened or retarded by suitably regulating the quantity of gas. It usually takes from 30—48 hours. The exhaust gases from the coke oven contain benzene vapour, 0.61 per cent.; ethylene, 1.63 per cent.; sulphuretted hydrogen, 0.43 per cent.; carbonic acid, 1.41 per cent.; carbon monoxide, 6.49 per cent.; 53.32 per cent. water; and methane, 36.11 per cent. They pass through the tube F into the gas-cooler K (Figs 4 and 5), which consists of an iron cylinder. Cold water trickles continually from m to n , over the plates l , and finds its exit at p . The gas enters at f_1 , passes upwards, is cooled, and leaves at g , from whence it passes through two more coolers. From the coolers the gas passes through the scrubbers W , which consist of large iron cylinders fitted inside with a number of perforated iron plates at 10 cm. interval. Water drips continually over these plates. The ammoniacal liquor and tar flow off at t . The gas loses 75 per cent. of its ammonia and nearly all the tar in the coolers, the remainder being deposited in the washers. The tar and ammonia are collected in the cisterns Y (Fig. 6). The coolers and washers are supplied with water from the tank X (Fig. 4).—H. T. P.

PATENTS.

Improvements in Gaseous Fuel-producing Apparatus. B. H. Thwaite, Liverpool. Eng. Pat. 6432, May 1, 1888. 1s. 3d.

THESE improvements consist mainly in the arrangement of valves and fittings to facilitate the alternate production of "water-gas" and "producer-gas" from two generators containing coal or other suitable carbonaceous material. Seven sheets of drawings are appended to the specification.

—A. R. D.

Improvements in the Process and Apparatus for making Illuminating and Heating Gas from Water in combination with Carbonaceous Substances. S. H. Linn, London. From J. Flannery, New York. Eng. Pat. 7400, May 18, 1888. 8d.

WATER-GAS is passed through a highly-heated annular retort in order to promote the dissociation of any excess steam, the oxygen thus set free converting its equivalent of carbonic oxide into carbonic acid. The resultant gases are caused to travel through a heated chamber to which liquid hydrocarbon is also admitted. Here the carbonic acid is again reduced to carbonic oxide, and the water-gas, mingled with hydrocarbon vapours, is converted into an illuminating gas of high candle-power.—A. R. D.

Improvements in the Mouthpieces and Lids, Doors, or Covers of Gas Retorts and Ovens, and other Vessels and Articles requiring Gas and Air-tight Joints. W. H. Westwood and E. T. Wright, Brierly Hill. Eng. Pat. 8551, June 11, 1888. 8d.

THE retort lid, instead of bearing or seating itself upon the extreme front end of the mouthpiece, is made to seat itself against a flexible joint external to the retort and some distance back from the front edge. By this means the joint is protected from any deposit of tar or dirt. The flexible material forming the joint is held in position by a ring piece either cast on or otherwise fastened to the retort mouthpiece.—A. R. D.

Improved Means of Increasing the Luminousness of Ignited Gas. J. Mactear, Westminster. Eng. Pat. 4124, March 8, 1889. 4d.

FINE platinum wire is braided or otherwise interwoven with cotton or other fibrous material, and the fabric so obtained is used for "mantles" in incandescence gas-lighting.

—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Perhydrides of the Higher Aromatic Hydrocarbons. C. Liebermann and L. Spiegel. Ber. 22, 779—781.

HAVING in a previous communication described the preparation and properties of chrysene hydrides, the authors have extended their researches to the perhydrides of other aromatic hydrocarbons. In each case the hydrocarbon (1 part) was heated with phosphorus (1.25 parts) and hydriodic acid (5 to 6 parts, sp. gr. = 1.7) for 12 to 16 hours at 250°—260°. *Phenanthrene perhydride*, $C_{11}H_{24}$ (prepared and examined by Lucas), solidifies in a freezing mixture, melts at -3° , and has a sp. gr. of 0.933 at 20° compared with water at the same temperature. It is not affected by cold fuming sulphuric acid, nitric acid and bromine, is gradually decomposed when boiled with acetic and chromic acids, but without yielding phenanthraquinone. When distilled over zinc dust some phenanthrene and a comparatively large amount of anthracene is obtained. *Retene dodecahydride*, $C_{14}H_{30}$, is a colourless oil exhibiting a bluish fluorescence. It boils at 336° (uncorr.). When distilled over zinc dust retene is formed in small quantity. It is readily affected by bromine, less readily by cold fuming nitric acid, and oxidised when boiled with chromic and acetic acids, but without yielding the quinone. *Picene perhydride*, $C_{22}H_{36}$, crystallises from alcohol in white needles melting at 175°, and boils above 360°. In its chemical properties it resembles the preceding compound. When distilled over zinc dust it forms picene, melting at 330°. *Picene-icosahydride*, $C_{22}H_{34}$, is liquid and boils at 360°. *Acenaphthene perhydride*, $C_{12}H_{20}$, forms a colourless liquid which boils at 235°—236° (uncorr.) and emits a peculiar sweetish odour. It is optically inactive. *Fluorene perhydride*, $C_{15}H_{22}$, is a colourless liquid boiling at 230° (uncorr.), and resembling the preceding perhydride in properties.

—D. B.

IV.—COLOURING MATTERS AND DYES.

Colouring matters derived from Benzidine Tetra benzyl Ether. A. Colson. Bull. Soc. Chim. 1889, 347—348.

QUIXOL is treated with alcoholic potash and the potassium salt so obtained with benzyl chloride to form the dibenzyl ether of quinol, $C_6H_4(O.C_6H_5)_2$. On nitration the mononitro compound, a yellow crystalline substance melting at

78°, is obtained. This reduced with zinc in alkaline solution forms a yellow substance melting at 140°, and a small quantity of a base, which dissolves in alcohol, and on boiling with dilute hydrochloric acid deposits the hydrochloride of a benzidine which becomes red on exposure to air. This benzidine combines in the cold with naphthol sulphonic acids, salicylic acid and phenols, forming colouring matters which dye cotton directly in an alkaline bath. They do not, however, possess the brilliancy of the colours derived from the tetramethyl- and tetra-ethyl ethers of benzidine.—O. H.

Amido-para-cresylmethyl ether. L. Limpach. Ber. 22, 789—791.

In a previous paper the author proved the position occupied by the amido group in amido-para-cresylmethyl ether by its conversion into hydroxytoluic acid. He now attempts to explain the position when a nitro group is introduced into this compound. *Nitroacetamido-para-cresylmethyl ether*, $C_{10}H_{12}N_2O_4$, is formed by the action of cold nitric acid on acetamido-para-cresylmethyl ether. It crystallises from alcohol in small needles, melting at 156°. *Nitroamido-para-cresylmethyl ether*, $C_{10}H_{10}N_2O_4$, is obtained from the acetyl compound by boiling with caustic soda. It crystallises in yellow needles, melting at 132°. *Diamido-para-cresylmethyl ether*, $C_8H_{12}N_2O$, forms a colourless compound, melting at 166°, with decomposition. Its aqueous solution becomes green when exposed to air, whilst its hydrochloric acid solution when added to an alkaline solution of α -naphthol yields a blue colouring matter, which was found to be an indophenol compound. As indophenols are yielded by para-diamines only, both amido groups must occupy the para position, and from this it follows that when diamido-para-cresylmethyl ether is nitrated, the nitro group must occupy the para position relatively to the amido group. *Orthoamido-para-cresylmethyl ether*, $C_8H_{12}NO$, is obtained by splitting up the amido group and subsequently reducing the nitro group. It fuses at 111°.

The author intends to pursue this investigation at a future date.—D. B.

β -Dinaphthyl-p-phenylenediamine. L. Rueff. Ber. 22, 1080—1083.

This body is obtained by heating *p*-phenylene diamine with an excess of β -naphthol to 200° so long as water continues to be formed. The reddish-brown crystalline mass is then boiled with dilute sodium hydrate, and the substance, after being powdered, is extracted successively with warm dilute hydrochloric acid, alcohol, and ether, and the residue is finally recrystallised from boiling glacial acetic acid, cumene, or nitrobenzene, but preferably from aniline. The substance crystallises in white plates, melts at 235°, and distils in a vacuum with slight decomposition above 400°. The constitution of the body is represented by the formula—

It is scarcely affected by dilute acids, but dissolves in concentrated sulphuric acid. If potassium nitrate or nitrite be added to this solution it turns greenish-violet and finally deep blue. The picrate, $C_6H_4(NH(C_{10}H_7)_2) \cdot 2C_6H_4(NO_2)_3OH$, is prepared by heating the diamine with an alcoholic solution of picric acid. It crystallises from a mixture of benzene and petroleum ether in small black needles, melting at 217°.

Dimethyl-di- β -naphthyl-p-phenylene diamine—

is obtained by heating the diamine with an excess of methyl iodide and methyl alcohol to 140°. The substance after purification crystallises from benzene in white plates melting at 180°, which are sparingly soluble in alcohol and ether. The solution of this substance in concentrated sulphuric acid is green and then blue; the addition of potassium nitrate causes a reddish-brown and of potassium nitrite a bluish-violet colouration. Acetyl chloride acts in the cold on the diamine, the reaction being completed by warming, with the formation of the compound

$C_6H_4(NC_2H_5O \cdot C_{10}H_7)_2$, a substance crystallising from hot benzene in white plates, melting at 210°. The dibenzoyl derivative, $C_6H_4(NC_6H_5CO \cdot C_{10}H_7)_2$, also crystallises in white plates melting at 220°, and is obtained by heating the diamine with benzoyl chloride to 140°. The substance is very slightly soluble in spirit and ether, but dissolves readily in hot benzene.—T. A. L.

Studies in the Methylene-blue Group. Aug. Bernthsen. Ann. 251, 1—97.

METHYLENE-BLUE has, according to the author's former researches, the constitution

and belongs, therefore, to the class of the indamines. In this compound the sulphur atom joins two benzene rings. Now it appeared to be of great interest to examine whether the sulphur atom could be introduced into one benzene ring and thus give rise by coupling this new body afterwards with a second benzene group (*i.e.*, dimethylaniline or similar compounds) to new methods for preparing Methylene-blue. Experiments in this direction have already been set on foot by Roth (Ger. Pat. 38,573). He treats Dimethyl-phenylene-green or its leuco base with sodium thiosulphate and potassium bichromate, and obtains compounds yielding on further treatment Methylene-blue. A second method, *viz.*, that of combining sulphur with one of the two generators of Dimethylphenylene-green had, however, not been attempted, and it seemed essential before trying it to study very exactly the constitution of the Methylene-red. Koch's formula of this body, $C_{16}H_{15}N_3S_2 \cdot 2HCl \cdot ZnCl_2 + 2H_2O$, is analytically correct, but its molecule is only represented by half of the above formula, *viz.*, $C_8H_9N_2S_2CH$. Former experiments had shown that part of the sulphur is very unstable in this body, and that reducing agents remove it as sulphuretted hydrogen. Ammonia acts on Methylene-red and forms a well-crystallised acid. The former product, resulting from the action of reducing agents on Methylene-red, is, indeed, a simple sulphur derivative of amidodimethylaniline—

amidodimethylaniline mercaptan. The ortho position of the NH_2 group to the SH residue can be easily proved by treating the zinc mercaptide with acetylchloride, when an anhydro base of the formula—

is formed. With nitrous acid the mercaptide forms, like all ortho compounds, an intramolecular diazothio-compound. By the action of ammonia on Methylene-red an oily product is formed, insoluble in water, consisting principally of the disulphide of the above-mentioned mercaptan, and of another strange product crystallising in yellow needles, which the author calls Supersulphide. Furthermore, another compound is contained in the alkaline solution—

Amidodimethylanilinedithiosulphonic acid. These experiments rendered it possible to explain the constitution of Methylene-red, which is—

If equal molecules of the mercaptan and dimethylaniline be oxidised in neutral solution or in a solution of hydrochloric or acetic acid by potassium bichromate, a green colouring matter is formed, easily soluble in water. The same product is formed if the bisulphide of dimethylaniline be treated in an analogous manner. Its formula is—

and the constitution of the base probably

Tetramethylindaminesulphide, or, as the author calls it for simplicity's sake "*Soluble*" or "*Sulphide-green*."

On oxidising amidodimethylanilinethiosulphonic acid with dimethylaniline a green indamine is formed, containing more sulphur than the above. Its formula is—

Tetramethylindaminethiosulphonate or "*Insoluble green*" or "*Sulphonic acid green*."

These green colouring matters can be easily converted into Methylene-blue or its leuco-compounds.

The Soluble or Sulphide-green produces Methylene-blue on standing, quicker on heating its aqueous solution, whilst an equivalent quantity of the leuco-base of the green indamine is formed. The Insoluble or Sulphonic acid green can be recrystallised from hot water without decomposition, but after boiling for several hours it is converted into leuco-methylene blue and sulphuric acid. The same action is produced by prolonged boiling with zinc chloride solution, whilst a brief boiling with it forms equivalent quantities of Methylene-blue and "Leucosulphonic acid green."

These reactions are easily comprehensible. Sulphide green and Leuco blue are isomeric. Sulphonic acid green differs from Leuco blue only by the SO_3 group, which can be readily eliminated.

These discoveries have an important bearing on the manufacture of Methylene blue. It is now possible to produce from the technically valueless Red the important Methylene blue. If further new methods could be discovered for producing sulphur derivatives of paradiamines, these reactions would assist in the preparation of a great variety of new compounds.

By acting with sulphuretted hydrogen on the oxidation product of amidodimethylaniline, the two hydrogen atoms of the sulphur compound were always attacked, and the two bonds of the sulphur served to unite two benzene rings together. But if one hydrogen atom were replaced by another group, different results might be expected, according to the formula—

(X refers to one element or group).

Amongst the known derivatives of sulphuretted hydrogen, its sulphonic acid, $\text{HS} - \text{SO}_3\text{H}$ was the first to be considered. This compound has been applied for making Methylene blue by a number of patentees (W. Majert, Ger. Pat. 13,281; W. Conrad, Ger. Pat. 11,014; Majert, Ger. Pat. 19,841; Ochler, Ger. Pat. 24,125; Moldau, Ger. Pat. 25,828; C. Roth, Ger. Pat. 38,573 and 39,757). But in most of these patents the action of this thiosulphonic acid was merely to reduce the nitrosodimethylaniline, or to serve as a source of sulphuretted hydrogen, and in most cases the yield of colouring matter was very small. An exception is to be found in Roth's patent (Ger. Pat. 38,573), according to which a considerable yield of Methylene blue can be obtained. Roth proposes to act with thiosulphonic acid in presence of an oxidising agent on the leuco base of an indamine, especially of Dimethylphenylene green. The author has shown in former researches that by application of sulphuretted hydrogen only small quantities of the desired product can be obtained. This circumstance, as well as the fact that unsymmetrical thionine colouring matters can be obtained according to Roth's patent, led to the consideration that the sulphur enters the molecule before the formation of the indamine, and experiment confirmed theory in this regard. On acting with thiosulphonic acid on the crude oxidation product of amidodimethylaniline, an abundant quantity of the sulphonic acid of the mercaptide is formed, identical with the above-described amidodimethylanilinethiosulphonic acid:—

The effective agent is the free thiosulphonic acid. But as this compound decomposes very quickly, it was found useful to apply it in the form of its stable but very acid aluminium and chromium salts.

As amidodimethylaniline, mercaptan can also be obtained from its homologues.

The author has prepared derivatives of *p*-amidodiethylaniline:—

- (a.) *Amidodiethylanilinethiosulphonic acid*,
 $\text{C}_6\text{H}_3\text{N(C}_2\text{H}_5\text{)}_2\text{(NH}_2\text{)(S.SO}_3\text{H)}.$
- (b.) *Amidodiethylanilinemercaptide*,
 $\text{C}_6\text{H}_3\text{N(C}_2\text{H}_5\text{)}_2\text{(NH}_2\text{)(SH)}.$
- (c.) *The corresponding disulphide.*

Derivatives of *Tetramethylphenylenediamine*:—

- (a.) *Tetramethylphenylenediaminethiosulphonic acid*,
 $\text{(CH}_3\text{)}_2\text{N.C}_6\text{H}_3\text{.N(CH}_3\text{)}_2\text{(S.SO}_3\text{H)}.$
- (b.) *Tetramethylphenylenediaminemercaptide*,
 $\text{(CH}_3\text{)}_2\text{N.C}_6\text{H}_3\text{.N(CH}_3\text{)}_2\text{(SH)}.$

Derivatives of *p*-Phenylenediamine:—

- (a.) *p*-Phenylenediaminethiosulphonic acid,
 $\text{C}_6\text{H}_3\text{(NH}_2\text{)}_2\text{(S.SO}_3\text{H)}.$
- (b.) *p*-Phenylenediaminemercaptide,
 $\text{C}_6\text{H}_3\text{(NH}_2\text{)}_2\text{(SH)}.$
- (c.) *The corresponding disulphide.*

Analogous derivatives of Tetramethylindaminethiosulphonate A.

- (1.) $\text{C}_{18}\text{H}_{23}\text{N}_3\text{S}_2\text{O}_3$ from Diethylthiosulphonic acid and Dimethylaniline.
- (2.) $\text{C}_{18}\text{H}_{23}\text{N}_3\text{S}_2\text{O}_3$ from Dimethylthiosulphonic acid and Diethylaniline.
- (3.) $\text{C}_{20}\text{H}_{27}\text{N}_3\text{S}_2\text{O}_3$ from Diethylthiosulphonic acid and Diethylaniline.
- (4.) $\text{C}_{14}\text{H}_{15}\text{N}_3\text{S}_2\text{O}_3$ from Dimethylthiosulphonic acid and Aniline.
- (5.) $\text{C}_{15}\text{H}_{17}\text{N}_3\text{S}_2\text{O}_3$ from Dimethylthiosulphonic acid and *o*-Toluidine.

- (6.) $C_{17}H_{21}N_3S_2O_3$, from Diethylthiosulphonic acid and *o*-Toluidine.
 (7.) $C_{14}H_{15}N_3S_2O_3$, from *p*-Phenylenediaminethiosulphonic acid and Dimethylaniline.

Analogous Derivatives of Tetramethylindaminesulphide B.

- (1.) $C_{18}H_{23}N_3S$, from Amidodimethylanilinemercaptide and Dimethylaniline.
 (2.) $C_{18}H_{23}N_3S$, from Amidodimethylanilinemercaptide and Diethylaniline.
 (3.) $C_{20}H_{27}N_3S$, from Amidodimethylanilinemercaptide and Diethylaniline.
 (4.) $C_{18}H_{17}N_3S$, from Amidodimethylanilinemercaptide and *o*-Toluidine.
 (5.) $C_{17}H_{21}N_3S$, from Amidodimethylanilinemercaptide and *o*-Toluidine.

Thionine Colouring Matters C.

- (1.) $C_{18}H_{23}N_3S_2Cl$, from the indamines A 1 and 2, B 1 and 2.
 (2.) $C_{20}H_{26}N_3S_2Cl$, from the indamines A 3 and B 3.
 (3.) $C_{14}H_{14}N_3S_2Cl$, from Amidodimethylanilinemercaptide and Aniline.
 (4.) $C_{13}H_{16}N_3S_2Cl$, from the indamines A 5 and B 4.
 (5.) $C_{17}H_{20}N_3S_2Cl$, from the indamines A 6 and B 5.
 (6.) Thionine, from *p*-Phenylenediaminemercaptide and Aniline.

Phenols can also be used for these reactions. From Amidodimethylanilinemercaptide and ordinary phenol, the Methylene-violet—

is obtained.

Amidodimethylanilinemercaptide and some of its derivatives.

Amidodimethylmercaptide from Methylene-red.—A one per cent. or two per cent. solution of Methylene-red is acidulated with hydrochloric acid, zinc dust is added and the mixture heated on the water-bath. It is decolourised, sulphuretted hydrogen escaping—

The mixture is filtered, boiled to remove H_2S , and ammonia is added to saturate the free acid. Then the zinc mercaptide is precipitated by sodium acetate. It could not be purified by crystallisation, but is easily soluble in hydrochloric and concentrated acetic acid. Ammonia does not decompose it; caustic soda dissolves it. If this solution be shaken with ether, air being admitted, a yellow basic oil is dissolved by the ether, which is no longer a mercaptan, but the corresponding disulphide. A dilute weak hydrochloric acid solution of the mercaptide shows on addition of ferric chloride a faint blue colouration, changing rapidly from a dirty violet-brown to a blue colour. In concentrated solutions of the mercaptide ferric chloride produces at first a blue colouration, which, however, soon disappears. Finally a blue colouring matter is formed as a precipitate, whilst the solution contains a violet-red colouring matter, which is rapidly decomposed. The blue consists partly of Methylene-blue, partly of another colouring matter not belonging to the group. If in these reactions H_2S be present Methylene-red is formed.

If the neutral solutions of the mercaptan hydrochloride and dimethylaniline hydrochloride be oxidised with potassium bichromate, a red colouration is formed, changing through blue into green. Tetramethylindaminesulphide is thus produced. On heating, the green colour changes into blue. Mercuric chloride throws down from the neutral solutions of the zinc mercaptide a dirty white precipitate; on heating the solution turns red. Mercurous nitrate oxidises the mercaptan to a dark red liquid.

The mercaptan can also be obtained by reducing the amidodimethylanilinethiosulphonic acid in a solution of caustic soda with zinc dust, or by reducing the disulphide or supersulphide in hydrochloric acid solution with the same agent.

The free mercaptan was obtained by treating the bisulphide or Methylene-red or the supersulphide with H_2S , until the solution was colourless. The sulphuretted hydrogen was removed by boiling in an atmosphere of carbonic acid. On addition of sodium acetate a yellowish oil was obtained, showing all the reactions of a mercaptan. Its hydrochloride could not be obtained in crystals; it is very soluble in water and alcohol.

Ethynylamidodimethylaniline mercaptan—

The mixture of the zinc salt with benzene is treated in a sealed tube with an excess of acetyl chloride for four to five hours at $100^\circ C$. The product thus obtained is nearly soluble in water; caustic soda precipitates an oil, soluble in ether. Gaseous hydrochloric acid separates the hydrochloride, the alcoholic solution of which, after purification with animal charcoal, crystallises in small white or light green needles or prisms.

Diazothiodimethylaniline—

3.5 grms. of sodium nitrite are added to a well cooled solution of 10 grms. of the zinc mercaptide, which is acidulated with sulphuric acid. First a diazo-compound is formed, which is instantaneously changed into the diazothiodimethylaniline. The base crystallises in long yellowish needles melting at $78^\circ C$, easily soluble in ether, alcohol, benzene, chloroform, with difficulty in petroleum spirit and water.

Ferric chloride does not produce any reaction.

Platinum chloride does not precipitate dilute solutions. In concentrated solutions it produces a precipitation of a double salt crystallising in large yellow needles.

Gold chloride produces a yellow double salt, crystallising in plates.

Potassium bichromate gives a dirty yellow crystalline precipitate. Zinc dust reduces the base to the mercaptan. Sulphuric or hydrochloric acid do not change the base on heating for a short time.

Fuming nitric acid forms a nitro-compound, which on addition of water is precipitated in fine yellow needles, insoluble in dilute hydrochloric acid.

On heating with nitric acid a compound is formed, soluble in ammonia with a red colour. The yield is, however, bad. Better results are obtained when the sulphonic acid is used instead of the mercaptan.

B-Amidodimethylaniline mercaptan disulphide is best obtained by oxidising the mercaptan with air. Freshly precipitated zinc mercaptide is suspended in water, ammonia is added and air passed through the mixture for 24 hours, the ammonia being removed from time to time. Its formula is—

It can also be obtained from amidodimethylanilinethiosulphonic acid, by treating it with an excess of caustic soda at $40^\circ-50^\circ C$.—

and from Methylene red with caustic alkalis; but in both cases the product is impure.

Amidodimethylanilinepersulphide crystallises from the solutions of the crude sulphide in benzene in beautiful yellow needles, melting at 97° C. The analytical results coincide with the formula $C_{12}H_{10}N_2S_2$. It is easily soluble in benzene and ether, with difficulty in petroleum spirit. Dilute acids dissolve it, but it suffers decomposition on standing, sulphur separating from its solutions. It becomes thus partly rechanged into the disulphide. Ferric chloride produces in the hydrochloric acid solution of the pure supersulphide a beautiful purple colouration due to the formation of *Methylene-red* and of a *blue colouring matter*. With dimethylaniline and chromates a deep purple colouration is likewise formed. Ferric chloride colours the hydrochloric acid solution in presence of H_2S a rose tint; if it be reduced before *Methylene-red* is however formed. The constitution of the persulphide is not yet cleared up; the author concludes from the formation of the red and blue colouring matter on oxidation with ferric chloride, that it is not a uniform body, but consists probably of two compounds.

Amidodimethylanilinthiosulphonic acid is obtained from *Methylene red*, by treating its aqueous solution (1:100) with dilute ammonia or caustic alkali, until it is decolourised. The alkaline solution is then acidulated with acetic acid and exposed for 24 hours in flat vessels to the influence of the air. A little ammonia is added, the disulphide removed by ether, and then the liquid, after acidifying with acetic acid, is treated with animal charcoal. After evaporation the sulphonic acid crystallises out on cooling and is purified by repeated recrystallisations. The yield is 20—25 per cent. of the weight of the *Methylene red*. It is with difficulty soluble in cold (1:270), easier soluble in hot water (1:25 or 30), with difficulty in alcohol, very easily in caustic or carbonated alkalis. The melting, i.e., decomposition point, was found on quick heating to be 201°—204° C., with gradual heating, 193—195° C.

Traces of iodine or ferric chloride produce in its dilute aqueous solutions a beautiful but unstable purple colouration, it disappears on addition of hydrochloric acid. Bichromates produce likewise a purple colouration. On being oxidised in presence of dimethylaniline, but absence of acids, "Sulphonic acid green" is formed. Mercuric chloride produces a white precipitate, passing, however, soon through a salmon colour into grey, whilst the solution is coloured red. Copper sulphate forms a blue precipitate, turning black on boiling. Platinum chloride produces a purple colouration, which disappears on boiling, a black precipitate being formed. Fuming hydrochloric acid precipitates in the dilute hydrochloric solution the hydrochloride in the form of small white prisms.

The thiosulphonic acid can also be obtained from *p*-amidodimethylaniline in the following manner:—10 grms. of neutral amidodimethylaniline sulphate are dissolved in 100 cc. of water, an aqueous solution of 5.5 grms. of potassium bichromate, acidulated with 1.5 grms. of acetic acid, are added. A mass of crystals is formed into which a solution of 22 grms. of sodium thiosulphate and 27 grms. of aluminium sulphate are poured. The product of the reaction is a clear liquid, from which, after standing, crystals of the sulphonic acid separate. Another way to prepare this compound is to treat the mercaptan with sulphurous acid and bichromate, or to treat the disulphide with sulphurous acid. The author describes further a series of analogous derivatives, which have been mentioned before, and were obtained from *amidodimethylaniline tetramethylid-aniline*, and *p*-phenylenediamine, *tetramethylindaminethiosulphonate*, *tetramethylindaminesulphide*. He also describes the methods for their conversion into *Methylene blue*.

If a neutral solution of equal molecules of dimethylanilinehydrochloride and amidodimethylanilinthiosulphonic acid be oxidised with potassium bichromate, the solution passes through red and a dirty violet into green and a copper looking resin or green needles, glittering like brass, are separated, which are recrystallised from hot water. Their formula is $C_{16}H_{19}N_3S_2O_2 + \frac{1}{2} aq.$ or—

This body can be reduced to a leuco-compound and is destroyed by treating with hydrochloric acid, a quinone being formed.

The sulphide green is formed in a similar way, by oxidising the mercaptan with dimethylanilinehydrochloride. Mineral acids decompose this compound, a quinone being formed. Reducing agents produce two leuco-compounds. When a sulphide green solution is left to itself it begins to turn blue, and after 2—3 days the reaction is finished. From the deep blue solution there separates out *Methylene blue* on addition of salt and zinc chloride. At the same time leuco-sulphide green is formed. Finally, boiling with zinc chloride produces only leuco-methylene blue. From the Thiosulphonic acid green the free base of leuco-blue is obtained by boiling its aqueous solution for some time. The author further describes a series of homologous green indamines, and blue colouring matters obtained therefrom, which vary in shade from a violet to a greenish blue. Their names have already been mentioned and their modes of preparation are analogous to those above given in more or less detail.

—A. L.

The Preparation of Rosanilines from Hydroxytriphenylcarbinols by the Action of Ammonia or Amines. O. Mühlhäuser. Dingl. Polyt. J. **271**, 459—461.

By the action of ammonia, or its primary and secondary substitution products, on hydroxytriphenylcarbinols, under pressure, rosanilines are obtained. The number of amido groups introduced depends upon the duration of the reaction. Aurin yields as final product pararosanine. The reaction is—

J. Persoz was the first to observe the action of ammonia on a mixture of hydroxytriphenylcarbinols, viz., corallin. Soon after, Rigond prepared the so-called azulin by the action of hot aniline on corallin. In 1877, Dale and Schorlemmer isolated trihydroxytriphenylcarbinol from corallin and treated this pure substance with ammonia. They obtained pararosanine. The same chemists obtained trimethylparosanine by the action of methylamine on trihydroxytriphenylcarbinol, and by the action of aniline and a little acetic acid on the same substance, prepared triphenylparosanine. In 1878, A. W. Hofmann prepared hexahydroxymethylparosanine by heating epinitonic acid and ammonia to 160—170° C. In 1881, Zulkowsky obtained an isomeric magenta from methylaurin and ammonia; and in the same year Breidl prepared triphenylparosanine from corallin and aniline chloride. Ewer and Pick obtained pure amidotriphenylcarbinols by the action of primary and secondary amines, especially methylamine, dimethylamine, aniline, *o*- and *p*-toluidines, xylydine, cumidine, and α - and β -naphthylamine on colouring matters of the following type:—

For example, hydroxytetramethyldiamidotriphenylcarbinol yielded with ammonia, aniline, and α -naphthylamine respectively, tetramethylparosanine, phenyl, and α -naphthyltetramethylparosanine respectively. The same chemists prepared from hydroxytetramethyldiamidotriphenylcarbinol-sulphonic acid and aniline, a phenyltetramethylparosanine-sulphonic acid.—H. T. P.

The Preparation of Amido-Triphenylmethanes from Amido-Triphenylcarbinols. O. Mühlhäuser. Dingl. Polyt. J. **271**, 457—459.

When a rosaniline base is submitted to the action of a reducing agent the carbinol is changed into the corresponding leuco-base. In the case of rosaniline itself, for instance, the reaction is as follows:—

A. W. Hofmann in 1861 first effected the reduction of rosaniline by means of ammonium sulphide, and also by zinc and hydrochloric acid. Two years later he prepared by similar means the leuco-base from triphenylrosaniline. L. Durand first employed zinc dust for reducing carbinols.

In 1867 H. Schiff showed that sulphurous acid could be used to reduce rosaniline. In 1872 Bulk reduced some of the sulphonic acids of the rosaniline series. The literature of the subject is given in the following table:—

When it is desired to reduce a colour-base in practice, it is dissolved in dilute hydrochloric or acetic acid, with the addition of alcohol if necessary; the solution is slightly warmed and zinc dust gradually added till the solution is decolourised. It is then filtered, diluted with water, and the base precipitated with soda. If ammonium sulphide be used the colour-base is best dissolved in alcohol, ammonium sulphide added, and the whole heated to 100° C. in a closed vessel. The alcohol is then distilled off, the residue poured into water, and the leuco-base purified by removing the sulphur.—H. T. P.

Oxidation of β -Naphthol. E. Ehrlich. Monatsh. Chem, 10, 115—122.

In preparing orthocinnamic carboxylic acid from β -naphthol (compare this Journal, 1888, 671) considerable quantities of a complicated colouring matter and resinous products are formed, and in addition there is formed a second crystalline acid, but only in small quantities (2 per cent.). This acid is best prepared by running a solution of 200 grms. of potassium permanganate in 4 litres of water, in a fine stream, into a well-cooled solution of 100 grms. of β -naphthol and 100 grms. of potash in 3 litres of water. After standing for a short time the whole is filtered, the filtrate slightly acidified with dilute sulphuric acid, again filtered from the coloured substance, the filtrate mixed with excess of dilute sulphuric acid, and, after 36 hours, the brown resinous deposit collected, washed with water and dried in the air. The solution contains considerable quantities of orthocinnamic carboxylic acid, which can be extracted with ether. The dry resinous product is repeatedly extracted with boiling alcoholic ether, the solution concentrated and the crystalline mass, which separates on cooling, first washed with alcohol and then boiled with a little dilute alcohol to remove orthocinnamic carboxylic acid. The residue is dissolved in boiling alcohol, hot water added to the filtered solution, and the precipitate recrystallised from alcohol.

The pure acid crystallises in colourless plates, melts at 281°, has the composition $\text{C}_{20}\text{H}_{12}\text{O}_4$, and is dibasic; it is insoluble in water, and only sparingly soluble in the ordinary solvents. The ammonium salt is very unstable and the silver salt is amorphous. The barium salt, $(\text{C}_{20}\text{H}_{11}\text{O}_4)_2\text{Ba} + 7 \text{H}_2\text{O}$, crystallises in colourless plates. The ethyl salt melts at 123°—124°.

A colourless crystalline dibasic acid, $\text{C}_{20}\text{H}_{14}\text{O}_4$, is obtained when the preceding compound is reduced with sodium amalgam; it melts at 223°—224°, but at a higher temperature it evolves carbonic anhydride. This acid is probably nearly related to the acid $\text{C}_{20}\text{H}_{11}\text{O}_8$, which Henriquez obtained by oxidising α -naphthol with potassium permanganate. (Compare Ber. 21, 1614.)—F. S. K.

PATENTS.

Improvements in and Relating to the Manufacture of Colouring Matters. H. H. Lake, London. From K. Ochler, Offenbach-on-the-Main, Germany. Eng. Pat. 7997, May 31, 1888. 6d.

Yellow and orange azo dye-stuffs, which dye cotton in an alkaline soap-bath without a mordant, are obtained, according to this patent, by combining one molecule of the *o*- or *m*-cresol carboxylic acids ($\text{CH}_3\text{OH}:\text{CO}_2\text{H} = 1:2:3$ or $= 1:3:4$) with diazotised benzidine or tolidine, and acting on these intermediate products with another molecule of cresol carboxylic acid, salicylic acid or toluylene diamine sulphonic acid. The cresol carboxylic acids are obtained from the isomeric cresols by the methods of Kolbe (Ger. Pat. 426), or of Schmitt (Ger. Pat. 29,939). The following are the methods for preparing some of the dye-stuffs:—18.4 lb. of benzidine are dissolved in 500 lb. of water and 48 lb. of hydrochloric acid of 20° B., and diazotised with a solution of 28 lb. of sodium nitrite in 150 lb. of water. This is then run into a solution containing 30.4 lb. of *o*-cresol carboxylic acid and 27 lb. of sodium hydrate in

600 lb. of water. The mixture is agitated, and after some hours the dye-stuff separates out as a yellow-brown powder which is filter-pressed and dried. It dyes cotton from a soap-bath light lemon-yellow. An orange dye-stuff is formed as follows:—2½ lb. of toluidine are diazotised, and to the solution are added 15·2 lb. of *o*-cresol carboxylic acid, 20 lb. of "calcined soda," and 300 lb. of water. The intermediate product thus formed is a gelatinous brown mass. To this is added a solution containing 20·2 lb. of toluenylenediamine sulphonic acid, 6 lb. of soda and 300 lb. of water. The whole is then stirred for 24 hours, raised to the boil, the dye-stuff precipitated with salt, filter-pressed, and dried. The acids are precipitated from their aqueous solutions by dilute acids as brown flakes. They dissolve with a violet colour in strong sulphuric acid.—T. A. L.

New Colouring Matters. H. H. Leigh, London. From R. G. Williams, Albany, U.S.A. Eng. Pat. 16,133, November 7, 1888. 6d.

ONE molecule of tetrazo-diphenyl, tetrazo-stilbene, tetrazo-fluorene, tetrazo-naphthalene, their homologues or sulphonic acids, is combined with one molecule of naphthylamine or one of the sulphonic acids of naphthylamine, and subsequently with one molecule of orcinol or its sulphonic acids, forming in this manner red dye-stuffs which dye cotton from an alkaline or soap-bath, the colour being fast to washing. 28 lb. of benzidine sulphate are diazotised and run into 25 lb. of sodium β -naphthylamine sulphamate, 100 lb. of sodium hydrate and 500 gallons of water. After stirring for 12 hours, 14·4 lb. of orcinol dissolved in water are added. The mixture is stirred for another 15 hours, raised to the boil, the dye-stuff salted out, filter-pressed and dried. Blue shades are obtained by using toluidine in place of benzidine, and also by employing Casella's naphthionic acid F in place of the naphthylamine sulphonic acid mentioned above. The colouring matters are insoluble in dilute acids, but soluble in alkalis and concentrated sulphuric acid.—T. A. L.

An Improved Manufacture of Para-diorg-benzol in Yellow Stable Crystals. S. Meyer, Berlin, Germany. Eng. Pat. 4404, March 13, 1889. 4d.

A HOT saturated solution of *p*-dihydroxybenzene (quinol) is treated with gaseous sulphurous acid. On cooling the solution, crystals of a bright yellow colour separate out. They contain a small quantity of sulphurous acid, and are much more stable than quinol both in the solid form and in solution. It is proposed to use this substance in a similar manner to quinol as a developer in photography.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

PATENT.

A Novel Method of Operating on Jute and Rhea Canes. J. R. Dry, London. Eng. Pat. 6581, May 2, 1888. 6d.

FOR the purposes of this invention the fibres are stripped off the stems in the form of "ribbons," which are laid in alternate layers, cross-wise, in crates or frames. The crates are then placed in tanks containing strong boiling soda solution. After remaining here for 15 minutes they are removed to another vessel containing a solution of soap, the strength being such that there is one pound of soap to five pounds of "ribbons." The solution is boiled for from 1½ to 3 hours. The material is rinsed in a bath of solution of soda of the same strength as that already referred to, and is then dipped in dilute sulphuric acid. If necessary, it is further treated with a weak solution of bleaching powder, after which it is thoroughly washed in cold water and dried by exposure to the air or by artificial heat.

—E. J. B.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

On some Chemical Properties of Wool and Allied Bodies, and on the Behaviour of these Bodies towards the Substantive Dyes. E. Knecht and J. R. Appleyard. J. Soc. Dyers and Colourists, 1889, 71—78.

THIS is a continuation of Knecht's paper "On the behaviour of the animal fibres towards the acid colouring matters" (this Journal, 1888, 621—623), in which the author endeavoured to produce further proofs in favour of the chemical theory of dyeing. By dissolving wool in sulphuric acid, and carefully neutralising the clear solution with soda, a precipitate was obtained which, when collected, washed, and dried, formed an amorphous brown powder, insoluble in water, but soluble in acids and alkalis. The solution in acids gave similar reactions with the acid coal-tar colours to those of the original solution. The authors have since endeavoured to purify this product, but found that after standing some time in the air it had become changed, being only partially soluble in alkalis; moreover, the yield from the wool was so small (less than 1 per cent.) that they were obliged to look for some better means for isolating the lake-giving constituent.

By dissolving wool in caustic soda,* and acidulating the solution with dilute sulphuric acid, a solution was obtained which showed properties identical with those of the original sulphuric acid solution. As the yield appeared to be much greater by this method, the authors therefore determined to discard the sulphuric acid solution and to restrict their attention to the solution in caustic alkali. After numerous futile attempts to isolate the lake-giving substance from the alkaline solution, they determined to try whether the so-called lanuginic acid, prepared from wool many years ago by Champion (Compt. Rend. 72, 330) possessed the property of precipitating the substantive dyes from their solutions. This was found to be the case, and they consequently prepared a quantity of this substance. The following was the *modus operandi*:—

About 500 grms. of Botany noils were first carefully washed and then dissolved in a moderately strong solution of barium hydrate. The barium was then precipitated by means of carbonic acid, and from the filtered solution the lanuginic acid was thrown down by means of lead acetate. After having removed all the excess of lead acetate by repeatedly washing with water, the lead salt was suspended in a large volume of water, and decomposed by sulphuretted hydrogen. The filtrate from the lead sulphide was evaporated to dryness. In this manner about 30 grms. of a brownish-yellow mass were obtained, which on grinding yielded a light dirty yellow powder. Here the authors were struck by a great discrepancy between their results and those of Champion, who described the product obtained as a light yellow deliquescent mass, while this was not in the least deliquescent. By working, however, exactly according to his method—viz., dissolving in barium hydrate, precipitating with carbonic acid, then with lead nitrate (instead of acetate), and decomposing the (perhaps not thoroughly washed) precipitate with sulphuretted hydrogen—on evaporating to dryness a product was obtained which corresponded exactly to his description; but it contained nitric acid, and there appeared to be no doubt that his also contained nitric acid. From analyses of the barium and lead salts, Champion ascribes to lanuginic acid the composition $C_{10}H_{20}N_2O_{10}$. The analyses agree indeed very closely with the formula, but he has left altogether out of consideration that the substance contains about 3 per cent. of sulphur, and his formulae cannot, therefore, be accepted as correct.

* The amount of caustic soda necessary to completely disintegrate the wool fibre was roughly estimated, and it was found that after boiling for three hours with 0·3 per cent. of caustic soda (of the weight of the wool), the fibre was not disintegrated, whereas when the amount was increased to 0·6 per cent., complete disintegration and almost complete solution had taken place.

The lanuginic acid obtained by the authors possesses the following properties:—It dissolves slowly in cold, easily in hot water. In alcohol it is sparingly soluble, in ether insoluble. The aqueous solution precipitates the acid and basic colouring matters forming coloured lakes. Tannic acid and bichromate of potash also yield precipitates. When heated to 100° it becomes soft and plastic, and this property is shown more strikingly by the coloured lakes, most of which melt at this temperature. If heated still further it swells up, turns brown and gives off a smell resembling that of burning wool. On ignition a considerable quantity of ash is left, which consists chiefly of barium carbonate. Suspecting that the reactions described might have been partially due to the presence of barium, the authors prepared a fresh quantity of the product by dissolving in caustic soda instead of barium hydrate, proceeding further as already indicated. The product obtained, which contained only a very small amount of ash, exactly resembled, however, the first product, not only in external appearance, but in all its properties.

The following further reactions were noted with the aqueous solution:—

Alum, in presence of sodium acetate, yields on standing a white precipitate.

Stannous chloride, in presence of sodium acetate, gives a similar precipitate.

Copper sulphate, in presence of sodium acetate, gives a light green curdy precipitate.

Ferric chloride, in presence of sodium acetate, yields a light brown precipitate.

Ferrous sulphate, in presence of sodium acetate, yields a dirty white precipitate.

Chrome alum, in presence of sodium acetate, a white precipitate.

Silver nitrate, in presence of sodium acetate, a white precipitate.

Platinum chloride yields a light yellow precipitate, which melts on heating.

Lanuginic acid parts with all its moisture at 110° C., the weight remaining constant when the temperature was raised to 130° C.

Lanuginic acid shows all the properties of a proteid, and may therefore be classed among the albuminoids; it is soluble in water at all temperatures, and its solution is not coagulated. With Millon's reagent, and with the double compound of phosphoric and tungstic acids, it shows the characteristic albuminoid reactions. An ultimate analysis yielded the following average percentage results:—

C=41.61; H=7.31; N=10.26; S=3.35; and O=31.44.
Total 93.97.

The nitrogen was estimated by Kjeldahl's method, and the sulphur by fusing with soda and saltpetre in a platinum crucible, and precipitating with barium chloride.

The product used in these estimations contained barium, which was estimated in the ash in the usual manner, and was taken into account in calculating the above percentages. It is noteworthy that this barium is combined so tenaciously with the lanuginic acid that it cannot be removed from the aqueous solution by means of carbonic acid. Another but more expensive method which the authors devised for isolating lanuginic acid is based upon the fact that the substance is completely thrown down by means of Night blue as a coloured lake. The method adopted was as follows:—Wool was dissolved in caustic soda, the solution slightly acidulated with sulphuric acid, and after filtering precipitated with a strong solution of Night blue. The Night blue lake was then decomposed with barium hydrate, which left behind the Night blue base in an insoluble state, while the lake-giving substance passed into solution. After precipitating the excess of barium with carbonic acid, the liquid was filtered and evaporated to dryness. The residue showed properties similar to the product obtained by the first method, and it appeared that the two substances were identical.

As is well known, wool is slowly changed by boiling water; at higher temperatures this change is still more marked. Leyer and Koller* first drew attention to the solubility of feathers, human hair, &c., in water at 200° C. Breinl describes the solution of wool in water at 200° C., and notes that the solution thus obtained also possesses the property of precipitating the substantive colouring matters. Previous to the publication of Breinl's results, the authors carried out the following experiment:—10 grms. of wool were heated with about 50 cc. of distilled water in a sealed tube for four hours to a temperature of 200°–230° C. On opening the tube there was a considerable pressure, and foul smelling gases, consisting chiefly of sulphuretted hydrogen, were given off. Most of the wool was dissolved, leaving a small quantity of a brown residue in the tube. The liquid, which was of a dirty orange colour, was strongly alkaline, owing to the presence of ammonia; it was distilled to about one-half of its volume, and the distillate, which was of a yellow colour, smelt strongly of ammonia. On evaporating the aqueous solution to dryness, a residue was obtained which resembled glue while hot, and, when cooled, solidified to a light brown hygroscopic mass, which weighed 5.5 grms. From the acidulated aqueous solution of this substance, ether extracted a light yellow oil, the smell of which resembles that of some of the higher fatty acids. The aqueous solution gave with sulphuric acid a yellow precipitate. Bichromate of potassium yielded with the filtrate from this a yellow precipitate. Hydrochloric acid also yielded a yellow precipitate, soluble in excess, and with this solution bichromate of potash gave a brown precipitate. Lead acetate yielded a light yellow precipitate, soluble in dilute nitric acid.

The acidulated aqueous solution yielded precipitates with the acid colours.

From these results it seemed probable that the aqueous solution of wool also contained lanuginic acid.

Horn boiled with caustic soda also dissolved, and the acidulated solution gave reactions similar to those of wool. Human epidermis, treated in a similar manner, was only partially dissolved, but the acidulated solution gave precipitates with the acid colours.

Sulphur in Wool.—Chevreul has shown that, by treating wool with alkalis, the greater part of the sulphur is removed as sulphuretted hydrogen, but he was not able to remove all in this manner. By steeping wool 28 times in lime water, 24 hours each time, and washing with hydrochloric acid between each treatment, he was able to reduce the percentage of sulphur to 0.46. The wool treated in this manner was no longer blackened by an alkaline solution of lead. It was thus shown that the sulphur in wool exists in two different forms.

Having found that lanuginic acid is not blackened by an alkaline solution of lead, the authors considered that the sulphur, which cannot be removed from wool by treatment with alkalis, must be contained in it, in this, or in a similar condition, and thought it of interest to estimate, quantitatively, the amount of sulphur which could be removed as sulphuretted hydrogen by another process.

For this purpose, the sulphur was estimated in wool by fusing with soda and saltpetre, and precipitating as barium sulphate. The sulphur removable by alkali was estimated by dissolving a known weight of wool in caustic soda, and passing the gas given off on acidulating, and boiling with sulphuric acid into decinormal iodine solution.

In the first experiment, wool containing 2.36 per cent. of sulphur was found to give off 1.66 per cent. as sulphuretted hydrogen; the rest, 0.70 per cent., remained in the liquid.

The percentage of sulphur (calculated on the total sulphur) evolved as sulphuretted hydrogen, was, according to this experiment, about 70 per cent.

In the second experiment, a different quality of wool was used. It contained 1.45 per cent. sulphur, of which 1.02 grm. (or again about 70 per cent. of the total) was given off as sulphuretted hydrogen. From the results of these two experiments, it would appear that the percentage of active to that of inactive sulphur in wool, is in a constant ratio.

Coloured Lakes from Wool.—Lanuginic acid precipitated in acidulated aqueous solution all the acid substantive dyes. The authors have prepared a large number of these coloured lakes, including those formed with Crystal scarlet, Orange, picric acid, Naphthol yellow S, Fast red, Naphthol black, Soluble blue, Acid violet, and indigo extract. All these lakes were intensely coloured; in cold water they were almost insoluble; in boiling water they mostly melted and partially dissolved, but separated out again on cooling. They were all easily soluble in alkalis, but re-precipitated by acids.

The *Picrate* was an orange precipitate, which, when finely ground, formed a bright yellow powder.

In preparing these lakes, the relative weights of the precipitates formed from the acidulated solution of wool in caustic soda were in nine cases roughly estimated. From 15 grms. of wool were obtained:—

	GRMS.	Per Cent.
Crystal scarlet lake	2.4	16.0
Fast red lake	2.5	16.6
Soluble blue lake	2.7	18.0
Orange lake,	3.1	20.6
Acid violet lake	2.9	19.3
Naphthol black lake	2.1	14.0
Picric acid lake	2.45	16.3

The lakes formed with the basic dyes may be obtained by adding the solution of the basic dye to the neutral solution of lanuginic acid. Most of these lakes differed from those formed by the acid dyes in being soluble in acids. In only one case—namely, that of magenta—was the weight of lake formed roughly estimated. 10 grms. of wool were dissolved in caustic soda, the solution carefully neutralised with sulphuric acid, and filtered. Excess of magenta was then added, and the precipitate formed was collected, washed and dried. It yielded 0.5 gm.

Maximum Amount of Colour absorbed by Wool in Dyeing.—In order to obtain an idea of the amount of colour which wool is capable of combining with, small pieces of flannel were dyed with a large excess of picric acid, Naphthol yellow S, and Tartrazin under similar conditions. The excess of colouring matter was then estimated in the residual solution in each case by titrating with Night blue. The amount of colour used was 50 per cent. of the weight of wool, and the dye-bath was acidulated with 50 per cent. of sulphuric acid. We found that the amount of acid used in dyeing did not materially affect the amount of colour fixed. Thus, whether 50 per cent. or 10 per cent. of sulphuric acid were used in dyeing with picric acid, exactly the same quantity was fixed. The maximum amount of colour had been fixed in the first hour; the amount fixed by prolonging the treatment to three hours was not greater. The estimation was effected by diluting the residual liquid to 2½ litres, and titrating the solutions thus obtained with a known quantity of Night blue.

The following amounts were fixed:—

(A.) PICRIC ACID.

	Time—1 hour.		Time—3 hours.
	I.	II.	III.
	Per Cent.	Per Cent.	Per Cent.
Amount fixed.....	13.00	13.3	13.20
Amount in solution.....	37.00	36.7	36.8
	50.00	50.0	50.00

These results were checked by estimating the actual increase in weight of a piece of flannel weighing 10 grms.,

after dyeing with 50 per cent. of picric acid, and were found to agree with those already obtained.

(B.) NAPHTHOL YELLOW S.—Time—1 hour.

	Per Cent.
Amount fixed	20.8
Amount in solution	29.2
	50.0

(C.) TARTRAZIN.—Time—1 hour.

	Per Cent.
Amount fixed.....	22.65
Amount in solution.....	27.35
	50.0

The temperature was in each case 100° C.

These figures show something very striking and interesting. Taking the amount of picric acid absorbed by wool as a basis, it is easy to calculate that the amounts of Naphthol yellow S and Tartrazin are almost exactly 1 and $\frac{3}{4}$ mol. respectively.

	Calculated.	Found.
	Per Cent.	Per Cent.
Picric acid	—	13.3
Naphthol yellow (1 mol.)	20.6	20.8
Tartrazin (1 mol.)	23.1	22.6
Crystal violet (1 mol.)	7.94	18.4

The amount of basic dyes absorbed is considerably less. Only one estimation was made, viz., in the case of Crystal violet. The amount of this dye absorbed, under similar conditions as already given, was found to be only 8.4 per cent. This corresponds to one-third of a molecule.

Summary and Conclusions.—The main object of this investigation was to establish as clearly as possible the correctness of the chemical theory of dyeing. During the course of their work a number of other points have been elicited, which the authors have considered of sufficient interest to include in the paper. They isolated from wool a substance soluble in water, which possesses most of the characteristic properties of keratine. It yielded precipitates with all the metallic salts used in mordanting, and also coloured precipitates with the substantive dyes. That actual chemical combination takes place was shown by the analysis of the picrate, which latter was found to contain sulphur as an essential constituent, whereas picric acid itself contains no sulphur. The percentages of carbon, hydrogen, nitrogen, and oxygen also point to the existence of a new compound.

It was not the wish of the authors to assert definitely that lanuginic acid exists as such in the wool, although it might be assumed that it is held there in an insoluble state by some other constituent of the fibre. They considered it more correct to assume that lanuginic acid is a simple decomposition product, or a more soluble form of that portion of the wool not yielding up its sulphur to alkalis.

Assuming, however, this hypothesis to be correct, all the reactions which take place in the mordanting and dyeing of wool might be explained by means of it. So far as mordanting is concerned, it had hitherto been asserted that when wool was boiled with solutions of the metallic salts a more or less complete dissociation of the salt took place, and the hydrate, or a very basic salt, became precipitated on the fibre. It appears now more probable that the mordants are not fixed in this manner, but actually combine with a constituent of the wool to form different chemical compounds, like those which have actually been produced from the solution of lanuginic acid. These compounds are capable of yielding coloured lakes with the adjective dyes, a property which is not possessed in all cases by the metallic hydrates themselves. Thus it was found that, whereas a solution containing Alizarin S, oxalic acid, and alum, could be boiled for an indefinite period without under-

going any apparent change, when lanuginic acid was added a bright scarlet precipitate rapidly formed at the boiling temperature. A similar reaction was noticed with cochineal, stannous chloride and oxalic acid.

The behaviour of wool towards the colouring matters is still more noteworthy. Here again the theory of simple mechanical absorption is quite out of question. This has already been made evident by the results of investigations already published by Knecht. The quantitative results which were obtained with picric acid, Naphthol yellow, and Tartrazin are especially noteworthy, and point unmistakably to strictly chemical reactions between the fibre and the colouring matters. The behaviour of Alkali blue was one which the authors could not at first easily explain, but they found subsequently that it was precipitated in neutral solution by lanuginic acid, and that the colour of the precipitate became considerably darker on the addition of sulphuric acid. An interesting result was also obtained with a solution of camwood in very dilute soda, which yields, with lanuginic acid, a copious red-brown precipitate, thus explaining the curious behaviour of this class of insoluble woods in wool dyeing.

Knecht further drew attention to the difficulty of completely removing the natural grease from wool by means of bisulphide of carbon. Wool was first treated with hydrochloric acid, in order to decompose any lime soap which the fibre might contain; it was then dried and extracted for three hours in a Soxhlet with bisulphide of carbon. Wool treated in this manner, then dissolved in caustic soda, gave with sulphuric acid a precipitate which when dried and ground was found on extracting again with bisulphide to contain grease which in its properties resembled cholesterol. From this it would appear that the woollen fibre contained grease in its interior not easy to remove on account of the dense character of the fibre.—E. K.

PATENTS.

Improvement in the Art or Process of Dyeing Cotton.
H. Gross, Crimmitschau, Saxony. Eng. Pat. 6029, April 23, 1888. 4d.

For the purpose of dyeing black on cotton, without the employment of a special mordanting process, a decoction of the common heath (*Erica vulgaris*) is added to the dye-liquor containing the dye-wood extract, together with catechu, copper sulphate, chromate of potash, borax, and bicarbonate of soda. The cotton is dyed in one bath, and it is claimed that a colour is obtained which is fast to light, whilst the rinsing-water is not appreciably polluted.—W. E. K.

Improvements in Apparatus for Treating Textile Materials with Liquids, Gases, or Vapours. W. Mather, Salford. Eng. Pat. 1172, January 22, 1889. 11d.

THE present invention relates to improvements in the construction of the apparatus described in Eng. Pats. 1912, 3096, and 8793 of 1885, and 10,053 and 15,343 of 1886, whereby the opening and closing of the doors is facilitated, and the charging, discharging, and circulation of the fluids employed are rendered more easy and effective.—E. J. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Contributions to the History of the Ammonia-Soda Process.
R. Lucien. Chem. Zeit. 13, 627.

As in the case of many important discoveries, so in that of the origin of the ammonia-soda process, there has been considerable contention on the question of priority.

The French have ascribed the honour of the discovery to Schöslöng and Rolland (1854), whereas it is easy to prove

that Hemming and Dyar, in 1838, had set up apparatus for manufacturing soda by the aid of this process; and still earlier, John Thom had made his friend, the late Dr. R. Angus Smith, acquainted with the intrinsic reaction on which the process depends. (This Journal, 1885, 527—529.) A. Vogel has, however, discovered an indication of the knowledge of this now well-known double decomposition in his father's notebook, and dated 1822.

W. Cesaro, of the University of Lüttich, in examining the correspondence of Fresnel, finds that this great physicist had tried the ammonia process in the year 1811, and had commended it to the attention of Thénard, Vanquelin, Darcet, and Chevreul; but these savants took no further interest in the reaction, and failed to recognise any important future for it.

The following are the extracts from the correspondence of L. Mérimée with his nephew, A. Fresnel. The delay in the reproduction of this evidence for so long is doubtless due to the fact that it is fragmentary, and the links in the chain must be connected; in other words, the extracts from several letters read together, in order that a correct conclusion may be arrived at.

Paris, 5 Août 1811.

... Mr. Vanquelin a paru flatté de ta confiance en lui et va répéter tes expériences. Je suis allé le revoir avant hier. Il n'avait pas encore commencé. Je pense, moi indigne, que tu ne l'es pas trompé et ce qu'il y a de piquant, c'est qu'un très habile fabricant de Soude, Mr. Darcet, a essayé ton moyen

31 Octobre 1811.

... Je rapporte encore de Mr. Vanquelin des promesses de vérifier tes expériences et l'opinion on il est qu'elles doivent réussir. Ce qui me donne un peu plus confiance dans ces nouvelles promesses, c'est qu'il doit charger son élève Mr. Chevreul et la besogne En attendant tu pourrais employer tes soirées à répéter un peu plus en grand ton expérience dans l'intention de déterminer ce que tu perds de carbonate d'ammoniaque.

Paris, 14 Avril 1812.

... Thenard m'a répondu que ton procédé est bon, mais il lui paraît plus dispendieux que celui qu'on suit Ce pendant il le trouve susceptible d'être exécuté en grand, surtout dans une fabrique de muriate d'ammoniaque.

If these passages be compared with a communication of L. Fresnel's, according to which the famous creator of the modern science of physical optics, prior to commencing his studies in this branch, busied himself with the question of the cheap production of soda from common salt, the conclusion is inevitably enforced that the gist of this question was the obtainment of soda from common salt and ammonium carbonate, with collateral formation of ammonium chloride.—W. S.

On the Disengagement of Chlorine during the Decomposition of Chlorates by Heat. W. Spring and E. Prost. Bull. Soc. Chim. 1889, 340—342.

THE authors refer to Wagner's work (Zeits. Anal. Chem. 24, 508), in which it is shown that pure chlorate of potassium does not yield chlorine when heated, while the commercial salt does; but the pure chlorate yields oxygen containing a small quantity of chlorine when heated in a current of carbonic anhydride. Wagner has attributed the origin of this chlorine partly to organic matters in the commercial chlorate and partly to the chlorate of calcium which it often contains; but he does not explain the manner in which these bodies act, and he does not connect the facts observed with other known phenomena.

The authors have attempted to supply this deficiency. They have submitted to the action of heat the chlorates of nine different metals (K, Na, Ba, Al, Ag, Cu, Zn, Pb, Hg), heating them, according to circumstances, in platinum or porcelain vessels, at first alone, dry or moist, then in contact with carbonic anhydride, silicic anhydride, and phosphoric anhydride.

In each case the manner of heating was varied, either rapidly or slowly. The following shows the results of the experiments:—

Proportion per Cent. of Chlorine disengaged.

Chlorate of	Chlorate heated slowly in contact with					Chlorate heated rapidly in contact with				
	Platinum.	Porcelain.	SiO ₂ .	CO ₂ .	P ₂ O ₅ .	Platinum.	Porcelain.	SiO ₂ .	CO ₂ .	P ₂ O ₅ .
K.....	..	0.02	1.08	0.27	2.18	0.03	0.05	0.72	0.50	55.85
Na.....	0.03	0.08	1.30	1.17	8.10	0.12	98.32
Ba.....	..	0.28	0.37	0.75
Al.....	97.87
Ag.....	..	0.10	1.11	0.56	8.65
Cu.....	..	12.55	14.70	13.20	91.20
Zn.....	..	11.45	26.78	48.50	95.10
Pb.....	..	8.05	10.76	16.00
Hg.....	..	3.70	2.00	2.10	100.00

The majority of the chlorates decomposed so quickly on being rapidly heated or in contact with P₂O₅ that it was impossible to measure the chlorine set free.

Conclusions.—The proportion of chlorine disengaged greatly varies with the nature of the chlorate and the circumstances. It is, however, noticeable that it increases when the chlorate has a relatively feeble base, and above all when the decomposition takes place in presence of an anhydride capable of forming a salt with the base of the chlorate.

According to the authors' view, the production of oxygen from the decomposition of the chlorates by heat is not an immediate but an indirect phenomenon. They split up at first into a base and an anhydride, according to the equation, $2\text{MClO}_3 = \text{M}_2\text{O} + \text{Cl}_2\text{O}_5$ (M being a monovalent metal). The anhydride is immediately decomposed into chlorine and oxygen, the former uniting with the base, thus:—

In cases where a notable increase of chloride is observed when the heat is rapidly applied, it appears that the chlorine is not carried away in the gaseous product if it be allowed time to react with the base, which is set at liberty for an instant, at least. The reaction is incomplete if the chlorine is carried away by its violence, or if the base form a salt on which the chlorine has no action (silicate or phosphate).

Finally, when the base is sufficiently strong (K₂O) the chloric anhydride may be further oxidised and a perchlorate produced.—W. M.

On the Action of Calcium Carbonate on Ammonium Chloride in Aqueous Solution. H. Schreib. Zeits. f. angew. Chem. 1889, 211—213.

CALCIUM carbonate has no action on a cold solution of ammonium chloride, but with the aid of heat decomposition takes place according to the equation—

The author finds by laboratory experiments that the decomposition may be complete whether the calcium carbonate or ammonium chloride be in excess, but much time is always taken up in the later stages of the reaction. The degree of fineness of the calcium carbonate exercises a very important influence on the rapidity of the reaction whilst the presence or absence of a small proportion of magnesium chloride is immaterial. The fact that this reaction yields carbonic acid along with ammonia would render it applicable to the treatment of ammonium chloride liquors in the ammonia-soda process if the time required were not so considerable, though the author considers that it might still be made available by the use of the finely-divided precipitate of calcium carbonate obtained in the manufacture of caustic soda, and the subsequent addition of a small proportion of quicklime to hasten the end of the reaction. The following table shows the mean results of two experiments in each case, in which 5 grms. of ammonium chloride in aqueous solution were decomposed with 7 grms. of each form of calcium carbonate in a fine state of division, in a flask through which a strong current of steam was passing. The evolved ammonium carbonate was received in successive portions of normal sulphuric acid:—

Material used.	Marble.	Ordinary Chalk.	Caustic Sludge.	Precipitated Calcium Carbonate.
20 cc. of N acid = 1.070 grm. of NH ₄ Cl = 21.40 per cent. decomposed in minutes	18	7	5	7
20 " " 1.070 " " 21.40 " " "	23	11	5	8
20 " " 1.070 " " 21.40 " " "	31	37	27	22
20 " " 1.070 " " 21.40 " " "	64	54	32	25
13 " " .695 " " 13.91 " " "	88	78	55	43
93 " " 4.975 " " 99.51 " " "	224	187	124	105

The author observes that the process would hardly be applicable to a continuous method of working, but would present no obstacle where the apparatus was worked intermittently.—G. H. B.

PATENTS.

New or Improved Method and Apparatus for Extracting Magnesia from Sea Water. L. G. G. Dandenart, Brussels, Belgium. Eng. Pat. 5953, April 24, 1888. 8d.

THE sea water is treated with slaked lime and the magnesium hydrate formed, allowed to settle by making the

liquors traverse very slowly extensive settling tanks. The slush deposited therein is carbonated, and the magnesium carbonate filter-pressed and dried.—S. H.

Improvements in Distilling, Purifying, and Concentrating Ammoniacal and other Liquids. P. A. Mallet and T. A. Pagniez, Paris, France. Eng. Pat. 7285, May 16, 1888. 8d.

THE object of this invention is the production of an apparatus by means of which a constant supply of solid reagents is obtained in distilling vessels. The distilling column, described in Eng. Pat. 3452 of 1884 (this Journal, 1885, 195) is connected with a hopper, at the bottom of which revolves an endless feeding screw at a convenient speed. The hopper is also fitted with a stirring mechanism, which prevents the clogging of the material inside the hopper. When distilling ammoniacal liquors burnt lime is continuously supplied by this hopper to the column.—S. H.

Improvements in the Process and Apparatus Used for Obtaining Anhydrous Liquid Ammonia. G. S. Page, New York, U.S.A. Eng. Pat. 8351, June 7, 1888. 8d.

AMMONIACAL liquor is treated with steam in a still to drive off the ammonia, which after passing through several purifiers, is absorbed in distilled water. The concentrated solution of ammonia thus obtained is heated by a steam-coil, and the gaseous ammonia again liberated, made to pass through a receiver containing caustic lime, which eliminates all aqueous vapours. The gas is then admitted into a compressor where it is converted into a liquid.—S. H.

An Improved Process for the Manufacture of Sugar of Lead. J. Löwe, Frankfurt-on-the-Main, Germany. Eng. Pat. 9858, July 6, 1888. 6d.

GRAVITATED or sheet lead is digested with acetic acid and such a quantity of oxygen-yielding compounds, such as nitric acid, nitric or nitrous salts of lead, sodium or potassium nitrate, lead peroxide, &c., as will just suffice to completely oxidise the lead. The whole is then heated nearly to boiling point, whilst the vapours evolved are condensed and permitted to flow back into the liquid. In order to carry out this process, 54—55 parts of dilute nitric acid of 1·2 sp. gr., 145 parts of 40 per cent. acetic acid, and 100 parts of lead are heated nearly to boiling until the metal is dissolved. The solution obtained, consisting of neutral lead acetate, is evaporated down to crystallisation.

—S. H.

An Improved Construction of Kiln for Burning Limestone. J. Winskill, jun., York. Eng. Pat. 4286, March 12, 1888. 6d.

THE kiln consists of two vertical chambers, which are connected by an elbow. Fuel and limestone are charged in alternate layers into the top chamber, while the burnt lime is withdrawn from time to time from the bottom. The working of the kiln is thereby rendered continuous.—S. H.

Improved Method and Apparatus for Calcination of Limestone. G. E. Carleton, Rockport, U.S.A. Eng. Pat. 4325, March 12, 1889. 8d.

THE object of this invention is the production of a kiln in which the heat is uniformly distributed, and the fuel thoroughly burned, whereby injury to the kiln is prevented and economy of the fuel secured. To attain this end, an air-blast is applied underneath the grate, while a jet of steam or water is at the same time injected in front or over the bed of coal in the fire-chamber. Provision is also made to supply an extra amount of air to the combustion chamber whenever a fresh supply of coal is added to the fire.—S. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

PATENTS.

Improvements in the Manufacture of Artificial Stone. A. C. Ponton, Parkstone, B. L. Mosely, and C. Chambers, Hastings. Eng. Pat. 5808, April 18, 1888. 6d.

VARIOUS materials, such as silicates, fluorspars, felspars, micas, &c., are taken according to the stone—marble or granite, for example—which is to be imitated. These substances can be either employed as fine powders or in pieces of varying size. The materials are mixed with a siliceous cement, averaging from 1 to 6 per cent. of anhydrous silica to each cubic foot of the fabricated hard stone, a plastic mass being thus obtained. The siliceous cement consists of silicates of potash or soda, with or without the addition of free silica. The mass thus obtained is moulded by great pressure to any required form, and then fired at a red or white heat in a porcelain kiln "until all, or nearly all, of the contained silica has been converted into the tridymite form of crystallisation." If the mass is too porous, it is again treated with the siliceous liquid until saturated, and then re-fired."

The term "Tridymite" is applied "not only to loose burnt sand and burnt flint, but also to a compacted or moulded mass of material after it has been fired in a kiln, in which case it includes the contained silica that was previously in a state of solution."—S. G. R.

Improvements in or Relating to the Utilisation of the Lime-Mud Refuse of Sugar and other Industries for Cement and other Purposes. J. S. Rigby, Liverpool. Eng. Pat. 7456, May 19, 1888. 6d.

THE lime-mud obtained in the manufacture of sugar, borax, &c., is mixed with clay or other earthy silicates and calcined, and is then used as ordinary cement. The carbonic acid gas liberated in the calcination is utilised for decomposing more saccharate of lime, or for other purposes. When the mud is impure, methods are indicated by which it can be purified; thus sulphides are removed by carbonic acid gas, and caustic alkali by washing.—S. G. R.

Improvements in the Manufacture of Portland Cement. A. Fleiner, H. Hauenschield, and A. Bauermeister, Switzerland. Eng. Pat. 7915, May 30, 1888. 8d.

THE substances, having been ground and mixed, are worked into a plastic condition with water. The mixture is then forced through an ordinary brick-moulding machine with cylindrical mouthpieces, and cut into lengths equal to the diameter of the cylinder. The pieces so obtained are made roughly spherical by being placed in inclined tubes having repeated corners or bends, and are then burnt in shafts or pit kilns, the process being a continuous one. To prevent the balls from caking together during the drying or burning, powdered limestone or some other non-smelting substance is strewn into the tubes down which the balls are rolling. The burnt cement should be drawn off at the bottom of the kiln at intervals not exceeding three hours.

—S. G. R.

A New Combination of Machinery for Mixing or Making Cement. T. C. Fawcett and T. Castle, Leeds. Eng. Pat. 8879, June 18, 1888. 8d.

THE substances to be employed, such as chalk and clay, are ground and at the same time mixed in an ordinary grinding pan with perforated bottom. They then pass into a mixer furnished with revolving screws, which first thoroughly mix and then force the mass between revolving rollers to be further ground. The homogeneous mixture is then conveyed by means of an endless travelling belt either to the kilns or to the drying floor. The specification is illustrated by drawings of the required machinery.—S. G. R.

Improvements in and Relating to the Seasoning or Preserving of Wood. R. Haddon, London. From S. E. Haskin, Avoca, U.S.A. Eng. Pat. 3875, March 5, 1889. *Sd.*

Wood is usually seasoned or "vulcanised" by being placed in a chamber, the air in which is heated by steam-coils. These being of great length, are very apt to leak, and the steam thus allowed to escape spoils the wood under treatment. The inventor therefore uses apparatus by which heated air, from which the moisture has been previously removed, is passed into the chamber. If the air, however, at a gradually increasing temperature be merely introduced, then at a certain point, the sap in the wood begins to boil and vaporise, thus damaging the quality of the fibre. In order to prevent this, the pressure in the chamber is increased *pari passu* with the temperature. As the wood is allowed to cool the temperature and pressure are again reduced simultaneously. The chamber is made of heavy riveted steel plates, and with removable cylinder heads. The wood is introduced on small trucks running on rails within the chamber. It is claimed that the process is much less expensive than the ordinary one, and also that the value of the seasoned article is increased. A drawing of the apparatus is given.—S. G. R.

X.—METALLURGY.

Aluminium. Sir H. E. Roscoe. Royal Institution Lecture, May 1889.

THE production of aluminium, previous to 1887, probably did not exceed 10,000 lb. per annum. The magnitude of the undertaking assumed by the Aluminium Company may be estimated, when we learn that they erected works having an annual producing capacity of 100,000 lb. of aluminium. The works now cover a space of nearly five acres. They are divided into five separate departments, viz., 1st, sodium; 2nd, chlorine; 3rd, chloride; 4th, aluminium; 5th, foundry; rolling, wire mills, &c.

1. *Manufacture of Sodium.* "Castner Process."

The vessels in which the charges of alkali and reducing material are heated are of egg-shaped pattern, about 18 in. in width at their widest part and about 3 ft. high, and are made in two portions, the lower one being actually in the form of a crucible, while the upper one is provided with an upright stem and a protruding hollow arm. This part of the apparatus is known as the cover. In commencing the operation, these covers are raised in the heated furnace through apertures provided in the floor of the heated chamber, and are then fastened in their place by an attachment adjusted to the stem; the hollow arm extends outside the furnace. Directly below each aperture in the bottom of the furnace are situated the hydraulic lifts, attached to the top of which are the platforms upon which are placed the crucibles to be raised into the furnace. Attached to the hydraulic lifts are the usual reversing valves for lowering or raising, and the platform is of such a size as, when raised, completely to fill the bottom aperture of the furnace. The charged crucible, being placed upon the platform, is raised into its position, the edges meeting those of the cover, forming an air-tight joint which prevents the escape of gas and vapour from the vessel during reduction, except by the hollow arm provided for this purpose. The natural expansion of the iron vessels is accommodated by the water-pressure in the hydraulic lifts, so that the joint of the cover and crucible are not disturbed until it is intended to lower the lift for the purpose of removing the crucible.

The length of time required for the first operation of reduction and distillation is about two hours. At the end of this time the crucibles are lowered, taken from the platforms by a large pair of tongs on wheels, carried to a dumping pit, and thrown on their side. The residue is

cleaned out, and the hot pot, being again gripped by the tongs, is taken back to the furnace. On its way, the charge of alkali and reducing material is thrown in. It is again placed on the lift and raised in position against the edges of the cover. The time consumed in making the charge is $1\frac{1}{2}$ minutes, and it only requires about seven minutes to draw, empty, recharge, and replace the five crucibles in each furnace. In this manner the crucibles retain the greater amount of their heat, so that the operation of reduction and distillation now only requires one hour and ten minutes. Each of the four furnaces, of five crucibles each, when in operation, are drawn alternately, so that the process is carried on night and day.

Attached to the protruding hollow arm from the cover are the condensers, which are of a peculiar pattern specially adapted to this process, being quite different from those formerly used. They are about 5 in. in diameter, and nearly 3 ft. long, and have a small opening in the bottom about 20 in. from the nozzle. The bottom of these condensers is so inclined that the metal condensed from the vapour issuing from the crucible during reduction flows down and out into a small pot placed directly below this opening. The uncondensed gases escape from the condenser at the further end, and burn with the characteristic sodium flame. The condensers are also provided with a small hinged door at the further end, by means of which the workmen from time to time may look in to observe how the distillation is progressing. Previous to drawing the crucibles from the furnace for the purpose of emptying and recharging, the small pots each containing the distilled metal (on an average about 6 lb.) are removed, and empty ones substituted.

The temperature of the furnaces are kept at 1,000° C., and the gas and air valves are carefully regulated so as to maintain as even a temperature as possible. A furnace in operation requires 250 lb. of caustic soda every one hour and ten minutes, and yields in the same time 30 lb. of sodium, and about 240 lb. of crude carbonate of soda. The residual carbonate, on treatment with lime in the usual manner, yields two-thirds of the original amount of caustic operated upon.

2. *Chlorine Manufacture.*—The usual method is employed. The gas is led into four gasometers, each of which is capable of holding 1,000 cu. ft. of gas, and is completely lined with lead, as are all connecting mains, &c.

3. *Manufacture of Double Chloride of Aluminium and Sodium.*—Twelve large regenerative gas furnaces are used for heating, and in each of these are fixed horizontal fire-clay retorts about 10 ft. in length, into which the mixture for making the double chloride is placed. These furnaces have been built in two rows, six on a side, the clear passageway down the centre of the building, which is about 250 ft. long, being 50 ft. in width. Above this central passage is the staging, carrying the large lead-mains for the supply of the chlorine coming from the gasometers. Opposite each retort, and attached to the main, are situated the regulating valves, connected with lead and earthenware pipes, for the regulation and passage of the chlorine to each retort. The valves are of peculiar design, and have been so constructed that the chlorine is made to pass through a certain depth of liquid, which not only by opposing a certain pressure allows a known quantity of gas to pass in a given time, but also prevents any return from the retort into the main.

The mixture for the retorts is made by grinding together hydrate of alumina, salt, and charcoal moistened with water, and by means of a pug mill the mass is forced out into solid cylindrical lengths; a workman with a large knife cuts the material into lengths of about 3 in. each. These are then piled on top of the large furnaces to dry. The retorts, when at the proper temperature, are charged by throwing in the balls until quite full, the fronts are then sealed up, and the charge allowed to remain undisturbed for about four hours, during which time the water of the alumina hydrate is completely expelled. At the end of this time the valves on the chlorine main are opened, and the gas is allowed to pass into the charged retorts. In the rear of each retort, and connected therewith by means of an earthenware pipe, are the condenser boxes which are built in brick. These boxes are provided with doors, and

also with earthenware pipes, connected with a small flue for carrying off the uncondensed vapours to the large chimney. At first the chlorine passed into each retort is all absorbed by the charge, and only carbonic oxide escapes into the open boxes, where it burns. After a certain time, however, dense fumes are evolved, and the boxes are then closed, while the connecting pipe between the box and the small flue serves to carry off the uncondensed vapours to the chimney.

The reaction which takes place is as follows:—

The chlorine is passed in for about 72 hours in varying quantity, the boxes at the back being opened from time to time by the workmen to ascertain the progress of the distillation. At the end of the time mentioned, the chlorine valves are closed and the boxes at the back of the furnace are thrown open. The crude double chloride, as distilled from the retorts, condenses in the connecting pipe and trickles down into the boxes, where it solidifies in large irregular masses. The yield from a bench of five retorts will average from 1,600 to 1,800 lb., which is not far from the theoretical quantity. After the removal of the crude chloride from the condenser boxes the retorts are opened at their charging end, and the residue is remixed in certain proportions with fresh material to be used over again. The furnace is immediately recharged and the same operations repeated, so that from each furnace upwards of 3,500 lb. of chloride are obtained weekly.

1. Aluminium. Reduction of the Double Chloride by Sodium.—This is effected in a large reverberatory furnace, having an inclined hearth about 6 ft. square, the inclination being towards the front of the furnace, through which are several openings at different heights. The pure chloride is ground together with cryolite in about the proportions of two to one, and is then carried to a staging erected above the reducing furnace. The sodium, in large slabs or blocks, is run through a machine similar to an ordinary tobacco-cutting machine, where it is cut into small thin slices; it is then transferred to the staging above the reducing furnace. Both materials are now thrown into a large revolving drum, when they become thoroughly mixed. The drum being opened and partially turned, the contents drop out into a car on a tramway directly below. The furnace having been raised to the desired temperature, the dampers of the furnace are all closed to prevent the access of air, the heating gas also being shut off. The car is then moved out on the roof of the furnace until it stands directly over the centre of the hearth. The furnace roof is provided with large hoppers, and through these openings the charge is introduced as quickly as possible. The reaction takes place almost immediately, and the whole charge quickly liquefies. At the end of a certain time the heating gas is again introduced and the charge kept at a moderate temperature for about two hours. At the end of this period the furnace is tapped by driving a bar through the lower opening, which has previously been stopped with a fire-clay plug, and the liquid metal run out in a silver stream into moulds placed below the opening. From each charge, composed of about 1,200 lb. of double chloride, 600 lb. of cryolite, and 350 lb. of sodium, about 115 to 120 lb. of aluminium is obtained. The composition of the metal, as shown by analysis, is 99.2 aluminium, 0.3 silicon, and 0.5 iron.

Eight or nine charges are laid on one side, and then melted down in the furnace to make a uniform quality, the liquid metal, after a good stirring, being drawn off into moulds. These large ingots, weighing about 60 lb. each, are sent to the casting shop, there to be melted and cast into the ordinary pigs, or other shapes, as may be required for the making of tubes, sheets, or wire, or else used directly for making alloys of either copper or iron.

The following table shows approximately the quantity of each material used in the production of one ton of aluminium:—

Metallic sodium	6,300 lb.
Double chloride	22,000 "
Cryolite	8,000 "
Coal	8 tons

To produce 6,300 lb. of sodium is required:—

Caustic soda	44,000 lb.
Carbide made from pitch, 12,000 lb. and iron turnings, 1,000 lb.	7,000 "
Crucible castings	2½ tons
Coal	75 "

For the production of 22,400 lb. double chloride is required:—

Common salt	8,000 lb.
Alumina hydrate	11,000 "
Chlorine gas	15,000 "
Coal	180 tons

For the production of 15,000 lb. of chlorine gas is required:—

Hydrochloric acid	180,000 lb.
Limestone dust	45,000 "
Lime	30,000 "
Loss of manganese	1,000 "

Properties of Aluminium.—After being cast it has about the hardness of pure silver, but may be sensibly hardened by hammering. Its tensile strength varies between 12 and 14 tons to the inch; ordinary cast iron being about 8 tons. Comparing the strength of aluminium in relation to its weight, it is equal to steel of 38 tons tensile strength. The fusibility of aluminium has been variously stated as being between that of zinc and silver, or between 600° and 1,000° C. The author's experience, that a small increase in the percentage of contained iron materially raised its point of fusion, was corroborated by Professor Carnelley, who found that a sample containing half per cent. of iron had a melting point of 700° C.; whereas sample containing 5 per cent. of iron does not melt at 700°, and only softens somewhat above that temperature, but undergoes incipient fusion at 730°.

Air, either wet or dry, has absolutely no effect on aluminium at the ordinary temperature, but this property is only possessed by a very pure quality of metal, and the pure metal in mass undergoes only slight oxidation, even at the melting point of platinum.

Leaf aluminium, when heated in a current of oxygen, burns with a brilliant bluish-white light. Heated in an atmosphere of chlorine it burns with a vivid light, producing aluminium chloride.

Alloys of Aluminium.—The most important alloys of aluminium are those made with copper. To arrive at perfection in making of these alloys, not only is it required that the aluminium used should be of good quality, but that only the best brands of Lake Superior copper should be used. The alloys all possess a good colour, polish well, keep their colour far better than all other copper alloys, are extremely malleable and ductile, can be worked either hot or cold, easily engraved, the higher grades have an elasticity exceeding steel, are easily cast into complicated objects, do not lose in remelting, and are possessed of great strength dependent on the purity and percentage of contained aluminium.

An important use of aluminium seems to be its employment in the iron industry, of which it promises shortly to become a valuable factor, owing to certain effects which it produces when present in the most minute proportions. Experiments are now being carried on at numerous iron and steel works in England, on the Continent, and in America. The results so far attained are greatly at variance, for whilst in the majority of cases the improvements made have encouraged the continuance of the trials, in others the result has not been satisfactory. On this point the author wishes to say to those who may contemplate making use of aluminium in this direction, that it would be advisable before trying their experiments to ascertain whether the aluminium alloy they may purchase actually contains any aluminium at all, for some of the so-called aluminium alloys contain little or no aluminium. Again, others contain such varying proportions of carbon, silicon, and other impurities as to render their use highly objectionable.

Aluminium added to molten iron and steel lowers their melting points, consequently increases the fluidity of the metal, and causes it to run easily into moulds and set

there, without entrapping air and other gases, which serve to form blow-holes and similar imperfections.

One of the most remarkable applications of this property which aluminium possesses of lowering the melting point of iron has been made use of by Nordenfelt in the production of castings of wrought iron.—F. S.

PATENTS.

A Method of sorting Minerals or other Bodies, and Apparatus therefor. G. Kilgour, London. Eng. Pat. 6348, April 28, 1888. 8d.

In place of the usual water-way with a running stream, a moving channel in still water is employed. The accompanying drawing illustrates the apparatus as a hand machine. A is a water tank; B a vertical spindle carrying a horizontal disc C with a portion of its centre cut away, and on which a spiral wall is built, producing a spiral channel D (Fig. 2),

Fig. 1.

Fig. 2.

from the periphery to the centre of the disc. The crushed ore is fed through the shoot K into the channel at the periphery of the revolving disc, where it is washed by the still water, which is prevented from revolving with the disc by fixed blades F. The periphery travelling more quickly than the part nearer the centre, the ore on its introduction is first washed with the strongest stream motion, after which it is subjected to the gradually diminishing force of the same, with the result that the heavier particles of material separate and settle down in the channel from the periphery to the centre in the order of their specific gravities, and the lighter portions or tailings are carried right through and washed through the opening G. G is an inclined shoot, on to which the tailings fall and down which they gravitate to the side of the tank, whence they can be removed by any means or by the chain elevator H. I is an inclined shoot into which the heavy material is discharged and conveyed to the other side of the tank to be removed by any convenient means. L is a bell operated by a lever L' connected with a blade L'', and signals when sufficient deposit has accumulated in the channel D to require removal. The channel is cleared by reversing the disc and lowering the scrapers M sliding on radial arms F.

A larger range of velocity can be obtained by having one or more discs placed below the first one in such a position that the material from the centre of the upper falls into the periphery of the lower one. The bed of the channel may be horizontal, or may slope at any angle or as a curve, either upwards or downwards towards the centre, according as the force of gravity is required to add to or diminish the differential effect of the spiral. Many advantages are claimed for this apparatus, amongst which may be mentioned that the amount of water necessary is extremely small; that since the tailings sink through the water the float gold is not carried away with them, but is collected on the surface of the water, from which it can be removed by an occasional revolution of a blanket; and that a channel 340 ft. long and 1 ft. wide will be obtained by a disc only 20 ft. in diameter. The apparatus can also be used as an amalgamator for the treatment of auriferous crushed ore, in which case the disc is made of copper and amalgamated in the ordinary way. Other drawings than the above are given.—A. W.

Improvements in Apparatus or Plant for preventing Loss in the Smelting of Ores, Metals, or Compounds of Zinc or other Oxidisable Metallic Substances, and Ores or Wastes of them. F. Fenton, Batley, and R. J. Partridge, Grasmere, From J. Woolford, Brioude, France. Eng. Pat. 7257, May 16, 1888. 8d.

THE vapours or gaseous compounds of zinc or other metals from furnaces are condensed by the aid of water spray or steam intermixed with air in a series of chambers and pipes through which they are driven by means of three fans. Water is placed in some of the chambers, and the spray is produced by a jet of water pouring into each fan. A crude diagrammatic sketch is given.—A. W.

Improvements in the Pneumatic Process of Manufacturing Iron, Steel, and other Metals. R. P. Wilson, F. J. Wall, F. A. Thurston, T. L. Bibbins, and W. L. Flanagan, New York, U.S.A. Eng. Pat. 8925, June 19, 1888. 4d.

THE idea is to prevent loss of iron due to oxidation at the end of the process of refining by lessening the blast towards the finish and introducing into the converter above the molten metal the vapour or gas of a hydrocarbon. The hydrocarbon atmosphere reduces the oxide of iron formed by the blast to metal.—A. W.

Improvements in the Production of Metals of the Earths and Alkaline Earths. A. Feldmann, Linden, Prussia. Eng. Pat. 9783, July 5, 1888. 6d.

THE claim is—"the process of producing metals of the earths and alkaline earths, which consists in adding to a haloid salt of the said metals or to a compound thereof with a haloid alkali salt, an oxide of an earth, earth alkali or alkali metal, which is more highly electro-positive than the metal to be separated out, or in adding to an oxide of the earth or earth-alkali-metal, a haloid compound of one or more earth-alkaline earth or alkali metals which is, or are all, more highly electro-positive than the metal to be obtained, in melting the mass and decomposing the same by the electric current." As instances, magnesium may be obtained from its double chloride with potassium by employing oxide of calcium or sodium, while aluminium can be made from its double chloride with sodium by means of oxide of calcium. Again, magnesium can be produced from its oxide by introducing the latter into a bath of fluoride of calcium and chloride of sodium, and so on. Basic pots are employed for melting. The electrodes may be made of carbon, or if alloys are required, both the negative and positive electrodes may consist of the metal to be alloyed. "There are no by-products produced in the melt."—A. W.

Improvements in Coating Iron with Antimony. N. C. Cookson, Newcastle-on-Tyne. Eng. Pat. 4428, March 14, 1889. 6d.

THE difficulty of coating iron with antimony is overcome by first applying to the iron a coating of tin or zinc, and then dipping it into melted antimony or applying the same by any other suitable means.—A. W.

Improvements in Storage Batteries. M. Immisch, London. Eng. Pat. 6907, May 9, 1888. 8d.

INSTEAD of using solid plates of the oxides of lead, the inventor clamps together strips of the active material between the teeth of leaden combs. Distance pieces of an insulating material are placed between the positive and negative plates.—B. T.

Improvements in or Relating to Electrical Fuses for Firing the Charge of Blast Holes and the Like. A. J. Boulton, London. From G. and C. Manet, Paris, France. Eng. Pat. 7408, May 18, 1888. 6d.

A PLATINUM wire of any convenient shape is placed inside the fuse and joined to wires connected with a source of electricity. The tube is then filled with detonating powder which can be ignited by the heat of the wire when the electric current passes through it.—B. T.

Improvements in Electric Batteries. H. Lahousse and Co. and C. Collé, Lille, France. Eng. Pat. 8965, June 18, 1888. 8d.

THIS battery is of the double-fluid type, the space between the outer cell and the porous pot being filled with granulated carbon packed round a carbon plate and sealed at the top with a layer of pitch; the top of the carbon plate and two pipes project through the pitch, one pipe serving as a means of supplying nitric acid to the cell and the other for the escape of air. The porous pot contains a zinc plate immersed in a solution composed of 35 grms. of bisulphate of mercury, 35 grms. of nitric acid, and 1 litre of water.

—B. T.

Improvements in the Form and Manufacture of the Frames, Plates, and Cells of Storage or Secondary Batteries. T. J. Haslam, jun., Dublin. Eng. Pat. 5095, March 25, 1889. 6d.

COMPRESSED beads or polygons of lead compounds are strung on rods of wood, bone, or other suitable material, the said rods being "strained" on frames of material unaffected by the electrolyte. This system of beads and rods forms the improved plate.—B. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

The Conversion of Oleic into Stearic Acid. P. De Wilde and A. Reychler. Bull. Soc. Chim. 1889, 295—296.

By heating oleic acid with 1 per cent. of iodine in sealed tubes to 270°—280° a mixture of fatty bodies results, containing 70 per cent. of stearic acid. This fatty acid can be separated by melting the contents of the tubes with tallow soap, boiling with acidulated water, and then distilling with superheated steam. One third of the iodine is obtained as hydriodic acid in the resulting liquors, but the remainder is difficult to recover, being retained in the tarry residue formed. Bromine acts similarly, yielding a solid acid melting at 51·5°, whilst with chlorine an acid melting at 31·5° results. The addition of colophony facilitates the reaction in each case. It is suggested that the unsaturated oleic acid first takes up iodine, that then hydriodic acid is given off, and this acts upon the oleic acid with the formation of stearic acid and regeneration of iodine.—C. A. K.

Walnut Oil. Thomas T. P. Bruce Warren. Chem. News, 59, 279.

THIS oil, obtained from the fully ripened nut of the *Juglans regia*, had many excellent properties, especially for mixing with artists' colours for fine-art work.

Walnut oil is largely used for adulterating olive oil, and to compensate for its high iodine absorption it is mixed with pure lard oil olein, which also retards the thickening effect due to oxidation. The marc left on expression of the oil is said to be largely used in the manufacture of chocolate. Many people seem to prefer walnut oil to olive oil for cooking purposes.

The value of this oil for out door work is demonstrated by the fact that a person who used it for painting the verandahs and jalousies of his house (near Como, Italy), some 20 years ago had not needed to repeat the operation. In this country, at least, walnut oil is beyond the reach of the general painter, and the pure oil is scarcely obtainable as a commercial article.

It was in examining the properties of this and other oils used as adulterants of olive oil that the author was obliged to prepare them, so as to be sure of getting them in a reliable condition as regards purity. The walnuts were harvested in the autumn of 1887, and kept in a dry airy room until the following March. The kernels had shrunk up, and contracted a disagreeable acid taste, so familiar with old olive oil in which this has been used as an adulterant. Most oxidised oils, especially cotton-seed oil, reveal a similar acid taste, but walnut oil has, in addition, an unmistakable increase in viscosity. The nuts were opened, and the kernels thrown into warm water, so as to loosen the epidermis; they were then rubbed in a coarse towel, so as to blanch them. The deoiled nuts were wiped dry, and rubbed to a smooth paste in a marble mortar. The paste was first digested in carbon bisulphide, then placed in a percolator and exhausted with the same solvent, which was evaporated off. The yield of oil was small; but probably, if the nuts had been left to fully ripen on the trees, without knocking them off, the yield might have been greater. It is by no means improbable that oxidation may have rendered a portion of the oil insoluble. The deoiled kernels gave a perfectly sweet, inodorous, and almost colourless oil, which rapidly thickened to an almost colourless, transparent, and perfectly elastic skin or film, not darkening or cracking easily by age. These are properties which, for fine-art painting, might be of great value in preserving the tinctorial purity and freshness of pigments.

Sulphur chloride gave a perfectly white product with the fresh oil, but when oxidised the product was very dark, almost black. The iodine absorption of the fresh oil thus obtained was very high, but fell rapidly by oxidation or blowing. A curious fact has been disclosed with reference to the oxidation of this and similar oils. If such an oil be mixed with lard oil, olive oil, or sperm oil, it thickens by oxidation, but is perfectly soluble. Such a mixture is largely

used in weaving or spinning. Commercial samples of linseed oil, when cold drawn, have a much higher iodine absorption, probably due to the same cause. Oils extracted by carbon bisulphide are very much higher than the same oils, especially if hot pressed.—W. S.

Californian Olive Oil. Chem. and Druggist, **34**, 1889, 791.

At a recent meeting of the Philadelphia College of Pharmacy a paper was read by Mr. Frank X. Moerk, in which Californian olive oil was compared with that of European origin. The samples of the American product were unquestionably genuine. In addition to finding that they were of a higher specific gravity (0.91717—0.91797) than the foreign oils, it was noticed that the reactions with acids were more intense and that the elaidin reaction was longer delayed. But the most remarkable fact was the extremely high percentage of free acids which the native oils contained. A good oil is generally expected to contain a mere fraction of 1 per cent. of free acids; but one sample of Californian contained as much as 8.33 per cent.; another (first pressing), 1.51; and a third (second pressing), 2.96 per cent. In the face of this observation the higher specific gravity is also remarkable, because free acids tend to lower that factor. Contrariness was further exemplified in the melting point of the free acids. Those from foreign oils melt at about 26° C., but the Californian acids went as low as 19° C. (the mean may be put down at 21° C.). The acids of the American oils at a temperature of 20° C. are viscid fluids containing in suspension the higher melting acids; the European oils are solid at this temperature. In addition to observing that the saponification equivalent of the American oil was higher (295 as compared with 292), there was also noticed a remarkable difference in the iodine absorption figures. The Californian oils absorbed 88 per cent. of iodine, while the foreign varies from 81 to 85 per cent. This is very probably due, the author thinks, to the presence of more olein than in the European oils, the melting point of the fatty acids also indicating this. There is another instance known, similar to this one, in which it has been proved that American fats differ in important respects from the same European fats—viz., lard. American lard has an iodine absorption of from 60 to 62 per cent., English lard from 51.5 to 62 per cent. From such results it would appear that climate and soil modify considerably the composition of the fats and oils, and for such variations due allowance must be made.—W. S.

PATENTS.

Improvements in the Manufacture of Soap. J. Jeyes, Plaistow. Eng. Pat. 8366, June 7, 1888. *Ad.*

To every 100 lb. fat employed for saponification, from 10 to 17 lb. of colourless and odourless mineral oil are added.—W. L. C.

Improvements in or connected with the Manufacture of Soap. C. A. Stitt, Edinburgh. Eng. Pat. 8604, June 12, 1888. *Ad.*

PARAFFIN oil, paraffin wax, or any mineral oil, is incorporated with the finished soap paste before it finally cools and hardens.—W. L. C.

Improvements in Candle-making Machines. J. M. Storrar, Glasgow. Eng. Pat. 8823, June 16, 1888. *Sd.*

This invention can be readily applied to existing machines, and has for its object the manufacture of candles whose outer layers are of different material from the inner core. This is accomplished by adding to the ordinary machine in which the moulds are fastened into a water-tight box, an annular mould which slides up and down in the ordinary one, and occupies the space to be eventually filled with the enamel or outer casing of the candle. Drawings are given.—W. L. C.

An Improvement in Cleaning and Polishing Compositions.

E. A. Ashley, Darlington. Eng. Pat. 9187, June 23, 1888. *Ad.*

GROUNDED flint, with or without barytes (sulphate of baryta) is incorporated with soap.—W. L. C.

An Improved Lubricating Composition. W. T. Hicks and J. Elliott, Middlesbrough. Eng. Pat. 9477, June 29, 1888. *Ad.*

To melted gutta-percha or caoutchouc, animal fat, pottery clay, and black lead are successively added, and the mixture is incorporated with a heat-absorbing material such as peat or turf, to prevent waste of the lubricant by overheating.—W. L. C.

An Improved Lubricating Compound. J. Annab, Orkney. Eng. Pat. 5028, March 22, 1889. *Ad.*

An emulsion of oil and water is produced by dissolving soft soap in the latter, prior to the addition of the oil.—W. L. C.

Improvements in the Treatment of Mineral Oils. T. H. Gray, Clapham Junction. Eng. Pat. 5132, March 25, 1889.

The oil is agitated with a solution of "chlorinated potash or soda," prepared by adding caustic alkali to chloride of lime solution.—W. L. C.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

Waterproofing Fabrics. E. Döring, Dingl. Polyt. J. 1889, 185—192.

A CRITICAL estimate of those processes of which the technical utility is fully proved, the author remarking incidentally upon the large number of abortive patents and impracticable recipes which characterise the literature of this subject. The processes are divisible into two groups: (1) the fabrics are filled with a compound of a fatty acid and earthy base, produced by double decomposition upon the fabric; (2) they are impregnated with water-resisting substances, applied either in the melted state or dissolved in a suitable solvent. In the former, the usual practice is to pad with aluminium acetate, dry, and pass through soap solution. In preparing the acetate solution the author recommends the decomposition of aluminium sulphate with lead acetate. Complete decomposition of the sulphate is not essential, but the presence of free acid should be avoided. In washing the precipitate of lead sulphate the author recommends attention to the provisions in Bunsen's well-known article on the subject (*Annalen*, **148**, 269—293). The padding solution should be kept at 140°, preferably by means of a steam-jacket or worm. The addition to the soap solution of wax, resin and caoutchouc has important advantages, and the following details are given for the preparation of the mixture. The quantities of materials may be calculated per square metre of fabric to be treated as under: 30 grms. of tallow soap, 25 grms. of Japan wax, 1.5 gm. of crude caoutchouc, previously dissolved to a 10 per cent. solution in turpentine or camphor oil, and 1 gm. of oil varnish to 500 cc. of solution. The Japan wax is first melted, and the caoutchouc solution and varnish stirred in; next a hot saturated solution of "liver of sulphur," in the proportion of 50 per cent. upon the caoutchouc, is added, and after thorough mixture the whole is added to the boiling soap solution. The "liver of sulphur," in addition to "vulcanising" the caoutchouc, has an important action upon the alumina mordant, by pre-

epitimating the hydrate of alumina and thus opening it up to the attack of the soap. In cases where it is required to colour the soap-bath, those coal-tar colours which are soluble in fats should be used, and dissolved with the wax and caoutchouc.

For impregnating with such mixtures as *Oleum Rosci* and black wax—which the author recommends as the best preservative—a special machine is described, the essential feature of which is a vertical series of three hollow cast-iron cylinders or rollers, the lowest turning in the mixture to be applied to the cloth, the two upper ones heated internally by steam; the middle roller is driven, and the upper and lower roller are kept in contact with it by means of adjustable screws. There are in addition the usual “breadthing” and guide rollers. After impregnation the goods are freed from the more volatile constituents of the bath by steaming them at about 7 lb. pressure in a closed chamber. The excess of steam is caused to pass through a condensing worm and the volatilised oils thereby recovered. A special form of “steamer” is described.—C. F. C.

Red Lead and Peroxide of Lead. J. Löwe. *Dingl. Polyt. J.* **271**, 472—477.

MOST commercial red lead consists of a mixture of oxide of lead with pure red lead. A small proportion of carbonate of lead is also generally present, formed by exposure to air after manufacture. To remove the free oxide of lead from commercial red lead various substances have been recommended, such as a solution of sugar of lead, or cold dilute acetic or nitric acid. Sugar of lead does not remove the carbonate of lead, while in the case of acetic and nitric acids there is danger of peroxide of lead being separated. The author recommends the use of a 10—12 per cent. solution of nitrate of lead. 200—300 cc. are sufficient for 20 grms. of red lead. This solution removes not only the oxide of lead, but also the carbonate and any traces of metallic lead. The red lead should be first digested for a considerable time, and then boiled with the nitrate of lead solution. The percentage of free oxide of lead in the samples examined varied from 16—31 per cent. The purified red lead is brighter in colour than the original sample. Nine samples of purified red lead were examined as to the percentage of peroxide of lead obtained from them by digestion with dilute nitric acid. They yielded from 25.4—25.7 per cent. PbO_2 . This agrees with the results obtained by Mulder, Phillips, Houton-Labillardière and Pichon, and points to the formula Pb_3O_4 for red lead, instead of the usually accepted formula Pb_2O_3 , which requires 31.88 per cent. of PbO_2 . At the same time it is probably possible by long-continued burning to obtain Pb_3O_4 ; for Dumas found that a sample of red lead, after three burnings, contained 33.2 per cent. PbO_2 . In the formation of red lead, not only the temperature but also the duration of the heating is of importance. As long as free PbO is present, and the composition of the colour is Pb_3O_4 , there is much less danger of the red lead being spoiled, owing to the formation of Pb_2O_3 , than when the colour has the composition Pb_2O_3 . The suggestion that red lead is a mixture of Pb_2O_3 and Pb_3O_4 is not compatible with analytical results. It is pretty certain that both compounds exist, but a red lead containing free PbO seems to have the composition Pb_3O_4 .—H. T. P.

PATENTS.

Improvements in the Manufacture of Sulphide of Zinc for Pigment or other Purposes. G. J. Geary, Manchester. From A. Keiller, Gothenburg, Sweden. Eng. Pat. 5371, April 11, 1888. 6d.

A SATURATED solution of a zinc salt is mixed with a saturated solution of some inert sulphate such as that of potassium, sodium, magnesium or ammonium, and precipitated with sulphuretted hydrogen. The zinc sulphide is filtered off, dried and heated, when it is found to be a pigment possessed of more “body” than it has when prepared in the ordinary way. The filtrate can be then saturated with metallic zinc, zinc oxide or carbonate, and used over again.—B. B.

An Improved Liquid for Use in the Softening and Preserving of Seaweed for Decorative Purposes. A. R. Ensor, Skegness, Lincolnshire. Eng. Pat. 18,821, December 24, 1888. 4d.

THE inventor claims a solution containing 3 parts of bergamot, 6 of borax, 12 of ammonia, 14 of gelatin, 25 of glycerin, and 40 of methylated spirits, into which the seaweed after being washed in water is dipped and allowed to dry.—E. J. B.

An Improved Composition for Covering and Protecting Surfaces. R. Morris, Doncaster, and W. T. Gent, Misterton. Eng. Pat. 844, January 16, 1889. 6d.

MIXTURES of a resin (“such as the resin of commerce”) with a metallic oxide and gypsum in varying proportions, with or without the addition of pigments to give them any desired colour, are made, and applied to the surface to be coated, either by liquefying them by heat after they have been spread over it in fine powder, or by solution of the resin in “naphtha” and a little boiled oil.—B. B.

An Improved Anti-fouling Compound for Coating the Bottoms of Ships and other Vessels. R. Seabrook, Grimsby. Eng. Pat. 4637, March 16, 1889. 4d.

FIVE pounds of “flour of sulphur” are “immersed in” 10 gallons of coal-tar, and one gallon of “turpentine” is then added. The whole is kept for a month with occasional stirring, the “supernatant liquid” drawn off and black lead added in the proportion of 3 oz. to one gallon, stirring diligently. The product may be applied in any convenient way and is said to adhere to the vessel longer than compositions already in use.—B. B.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

Oxidation of Gelatin with Potassium Permanganate, and the Relation of Gelatin to Albumen. R. Maly. *Monatsh. Chem.* **10**, 26—38.

WHEN the purest commercial gelatin (1 part) is dissolved in water, the solution gradually mixed with potassium permanganate (2 parts), and kept for 44 days at the ordinary temperature, it yields a mixture of very complicated acids analogous to the peroxy-proto acid obtained in a similar manner from albumen (*Monatsh. Chem.* March 1888). If, after filtering the manganese oxide, the solution be evaporated to dryness, the residue extracted with water, neutralised with acetic acid, and mixed with lead acetate, a copious white precipitate is produced, and the filtrate gives a further precipitate on adding mercuric chloride. The two precipitates contain the whole of the oxidised gelatin, and the filtrate does not show the biuret-reaction. When the precipitates are decomposed with sulphuric acid and sulphuretted hydrogen, respectively, acid syrups are obtained, from which, however, no crystalline compound can be isolated. Both syrups show the biuret-reaction, but do not give Millon's reaction, and no blackening occurs with potash and lead acetate. When heated, strongly acid vapours are evolved and the smell of burning gelatin is observed. When the acid syrup obtained from the lead precipitate is boiled for about 12 hours with excess of baryta, ammonia is evolved, and large quantities of barium oxalate, containing traces of the carbonate and phosphate, separate from the solution. No change takes place on further boiling, and a small portion of the solution, after freeing from baryta gives a dark blue colour with copper acetate, but does not show the biuret-reaction. If the whole be now filtered, mixed with a further quantity of baryta, and heated at 120°—190° for about 36 hours, an ammoniacal, tarry liquid is obtained. After filtering from small quantities of barium carbonate, ferric hydrate and organic substances, the solution is distilled, the distillate neutralised with hydrochloric acid

and again distilled. Pyrroline, and perhaps also traces of indole, were found in the distillate, and the residue contained ammonium chloride, a brown amorphous substance, perhaps pyrroline red, and a small quantity of a base which was probably aniline. The residue from the first distillation contained leucin, acetic acid, propionic acid, benzoic acid and glutamic acid. After isolating these compounds the mother-liquors were again heated with baryta, but no new product was obtained.

The acid syrup obtained from the mercury precipitate was also treated as described above. Ammonia, oxalic acid and pyrroline were obtained, but only traces of glutamic acid were isolated, and benzoic acid was entirely absent. A large quantity of propionic acid was produced, and the quantity of leucin obtained was much larger than in the case of the lead precipitate. The last-named product occurred either mixed or combined with an equivalent quantity of amido-valeric acid.

When gelatin is oxidised with a hot solution of potassium permanganate fatty acids (principally caproic), benzoic acid, and succinic acid are formed.

These results show that gelatin and albumen behave in the same way when treated as described above. The formation of isoglyceric acid in the case of albumen (loc. cit.), and its non-formation from gelatin, is, the author considers, of little importance, even if not due simply to slight differences in the conditions of the experiment. It has hitherto been generally supposed that albuminoids proper yield aromatic decomposition products (tyrosine, indole, phenol), whilst gelatinoids do not yield any such compounds. The author points out that this distinction cannot be maintained, as, although gelatin does not yield indole or tyrosine, it gives benzoic acid. This difference in behaviour shows no constitutional difference between albumen and gelatin, because oxyprotosulphonic acid (Maly, *Monatsh. Chem.* 1885, 91), which is simply oxidised albumen, does not yield tyrosine but benzoic acid when boiled with baryta under pressure. Again, albumen yields both indole and phenol; oxyprotosulphonic acid, on the other hand, gives neither compound. Gelatin behaves, therefore, exactly like oxidised albumen, and oxyprotosulphonic acid stands intermediate between gelatin and albumen.

All experiments on the decomposition of gelatin and albumen which have been made up to the present time show that there is no important and distinct difference between these two substances. Gelatin is as much an albuminoid as fibrin or casein, and a classification into gelatinoids and albuminoids cannot be upheld.—F. S. K.

PATENT.

A New or Improved Artificial Leather. N. F. E. Rapenud. Entreehaux, France. Eng. Pat. 8221, June 5, 1888. 64.

LEATHER refuse or cuttings is ground and made into a fibrous paste with which is mixed a glue or gelatinous compound containing fatty matter and glycerin. The paste may be spread and formed into plates by machinery, to be afterwards rolled and calendered. As exemplifying the composition, the following proportions may be taken:—leather refuse, 78–90 parts; gelatin, 4–8 parts; tallow, 1–2 parts; glycerin, 5–12 parts.—B. H.

XV.—AGRICULTURE, MANURES, Etc.

Propagation and Prevention of Smut in Oats and Barley. J. L. Jensen. J. Roy. Agric. Soc. Eng. 24, 397–415.

HAVING made a number of observations during the last two or three years on the disease known as "smut" on the oat and barley plants, the author is led to believe that its propagation takes place principally at the time of flowering, when the husk opens to allow the stamens to protrude, thus admitting the spores of the fungus. In one series of experiments in which oats were (1) dusted merely *outwardly* with the spores of *Restilago segetum*, (2) husk removed and spores dusted on the bare kernel, diseased plants were only

found in the latter crop, and that consequently, in order to prevent "smut," the *kernel* must be dressed with the preservative, and not merely the outside husk.

A series of experiments was made to determine the relative values of the different preservatives recommended for the prevention of smut—(1) sulphate of copper; (2) sulphate of copper, followed by quicklime; (3) sulphuric acid and water; (4) quicklime, subsequently followed by common salt, were tried, and, in addition, the effect of hot air, both dry and moist, and warm water. The results obtained showed that while the mineral preservatives all had a nearly perfect action so far as the prevention of smut is concerned, the crop suffered more or less from their application. Dry heat at 50°–51° had apparently no effect on the spores, moist heat destroyed the spores but damaged the crop also. Water at 51°–56° acted perfectly, both destroying the smut spores and leaving the seed corn uninjured. The author, after a yet more extended experience of the application of warm water, recommends it. The seed corn, placed in a basket lined with linen, is dipped into warm water at 55° four times, by which the temperature of the water is lowered so much that he recommends having a second vessel ready and the corn is rapidly dipped in the second vessel five or six times, after which it is cooled by pouring cold water over it, and it is then spread out on the floor to cool thoroughly.—J. W. L.

Society for the Promotion of Moor-Cultivation in Germany. Chem. Zeit. 19, 297–298.

VOX WANGENHEIM, in a long article on moor-cultivation, treats more especially of low-lying or submerged moors (Niederungsmoore) than of those moors which are above the surface of the water (Hochmoore). The former are cultivated in embankments covered with layers of soil alternating with channels for drainage (Moor-Damncultur). The kind of soil suitable for covering the embankments is a question of importance. Coarse river sand, almost free from clay, becomes very dry and cracks, so that seeds sown in it either perish or develop badly. Fine sand from moor subsoil remains moister than the coarse sand, and upon it hemp and flax grow very well, whereas peas half die off and half thrive, when the roots reach the moor. Meadow-marl, with 78 and 86 per cent. of calcium carbonate, has a somewhat similar effect; in the 86 per cent. soil the hemp grows better, but the peas and flax are not so good. Heavy marsh soil gives rise to good development, but where exposed to heat forms a hard crust which has to be broken up. Under suitable conditions all these soils may give good results. Sand permits of deep sowing, clay is appropriate for such crops as are sown in moister and cooler seasons of the year.

In the discussion which followed, calcareous sandy loam was recognised as of general utility. Intercepted drainage gives rise to mouldiness and should be prevented. All moors do not pay for sanding, those which are too submerged, for instance. Sanding is most effective on moors which suffer from frost, or are ferruginous and become readily dry. In sanding, 4 centimetres form too thin a layer, 8 cm. are about sufficient, but 11 cm. still better to ensure good and even crops. With regard to manuring, Fleischer's views are confirmed, and a moor not receiving any fertilising water, or fertile soil as covering, will yield 8,000 kilos. of hay per hectare for a dressing of 800 kilos. of kainite and 300 to 400 kilos. of basic slag per hectare. Systematic succession of crops is recommended for moor land.

For peat-moss litter the surface of high moors is very well adapted, which is not always the case with low moors, hence some manufacturers neglect to utilise suitable low-moor peat. The compression of the peat should be to about two-fifths or one-third the original bulk, sometimes it is not carried far enough and the finished product retains too much water. In order to obtain uniformity in the size of bales and convenience in estimating quantities of peat-moss, it is decided to make each 0.5 cubic metre, measuring 1 metre long; such a bale of good average-dry peat litter weighs 125 kilos. Its power of absorbing moisture and noxious odours, its disinfectant characteristics and the proportion of plant nutritives it contains, render it useful as

a general litter, as a packing material for perishable articles of food, and as a manure. As litter for horses, &c. it has been found, by some, lacking in uniformity and with too great absorptive power for moisture and noxious vapours; on the other hand, others speak highly of its beneficial influence on the growth and cutting qualities of the hoofs. Many prefer peat litter to straw litter, and think that if it could be obtained colourless its extended adoption would be even more certain.—D. A. L.

Potato Culture A. Girard. *Compt. Rend.* **108**, 412—415.

See under XVII., page 472.

XVI.—SUGAR, STARCH, GUM, Etc.

Improvements in the Manufacture of Starch, Dextrin, and Grape-Sugar. Dingl. Polyt. J. **271**, 512—515.

STARCH sugar of commerce mostly consists of a mixture of 64—66 per cent. of fermentable sugar, 18—20 per cent. of unfermentable organic matter, and 14—18 per cent. of water, and is considered almost useless for the preparation of wine and liqueurs and for brewing purposes; moreover, its employment for the manufacture of these products is illegal in Germany, Austro-Hungary, and in France. Although many attempts to obtain a purer product have been made during the last few years, the methods hitherto proposed have been found to be of no practical utility.

Seyberlich and Trampelach have recently worked out a process for preparing pure grape sugar on a commercial scale, which has been patented in most countries. The original experiments were made at the starch-sugar works owned by P. Brandenburg in Riga, 1,000 kilos. of air-dried starch being operated upon at a time. The process is, in its essential points, directed towards the method devised by Soxhlet (this Journal, 1882, 376). The patentees consider the purification of starch-sugar by means of methyl alcohol as practised by Soxhlet impracticable, on the ground of the high price of alcohol and its great volatility; moreover, the expenses incurred in evaporating vast quantities of liquors and the necessity of employing excessive quantities of charcoal, coupled with certain difficulties attending the subsequent crystallisation of the sugar, present great obstacles to the successful working of the process. The large consumption of charcoal is brought about by the fact that the saccharification is effected by means of sulphuric acid under pressure, the high temperature to which the mixture is exposed frequently giving rise to the formation of dark-coloured products, which require the use of excessive quantities of charcoal for the purpose of decolourisation. Seyberlich therefore made some trials to determine the effect of other acids. Hydrochloric acid being unsuitable, nitric acid was tried, the result being satisfactory in every respect. The saccharification was conducted in open vessels, one part of starch being mixed with two parts of water, and the mixture treated with 0.5 per cent. of nitric acid on the weight of air-dried starch.

For the preparation of the raw sugar the authors propose to make the starchy material into a milk with water, boil with nitric acid, neutralise the solution, then render it slightly alkaline, filter, evaporate to 35° B., cool to 18° C., and allow to crystallise in copper pans. The resulting sugar is then subjected to hydraulic pressure, the pressed cakes of raw sugar thus obtained containing 88 per cent. of real sugar, 10 per cent. of water, and 2 per cent. of impurities. The syrup is concentrated for crystallisation, and the final liquors (molasses) worked up for sugar after removal of the nitric acid and salts by means of sulphurous acid. The raw sugar is refined by dissolving it in water, bringing the solution to a density of 32° B. (measured hot), decolourising with charcoal (10 per cent. on the weight of raw sugar) at 80°—90°, and filter-pressing. The colourless sugar solution is then allowed to crystallise, and the product freed from the mother-liquors by pressing. The solution

is concentrated for the purpose of separating a further batch of crystals, whilst the final syrup is mixed with a fresh portion of raw sugar to be refined. By melting the sugar-cake and heating to boiling, then adding some crystals of anhydrous grape-sugar and allowing the mixture to cool, anhydrous grape-sugar is obtained. When this is broken up and sifted a crystallised product resembling cane-sugar is obtained. It contains 98 per cent. of sugar and 2 per cent. of water.—D. B.

Saccharification by means of Diastase. A. Reyehler. *Bull. Soc. Chim.* 1889, 286—295.

A SERIES of experiments are described on the saccharification of starch by means of solutions of gluten. As solvents, hydrochloric acid, acid sulphate of potassium, phosphoric acid, the acid phosphates of the alkalis, acetic, tartaric, lactic, and formic acids, were found most satisfactory, the solutions being obtained by treating fresh, well-washed and pressed gluten with the solvent at about 40° C. for 4—5 hours. These solutions do not coagulate on boiling; on addition of caustic potash drop by drop, a precipitate is formed, soluble in excess; mercuric chloride has no action and potassium ferrocyanide produces a precipitate soluble in acetic acid. With an alkaline solution of a copper salt a slight reduction takes place, probably due to the presence of a little saccharified starch; the solutions also give Lintner's reaction for diastase, viz., the blue colouration with hydrogen peroxide and tincture of guaiacum, but previous boiling or the addition of a concentrated solution of a base or of an acid prevents the formation of the colour. The resemblance of these solutions of gluten to diastase is borne out by their action on starch, which in the form of starch paste is converted by them at a temperature of 50°—60° into soluble products with a powerful reducing action. To effect the change the solution must be very dilute and very slightly acid; previous boiling prevents the action. In one experiment 2 grms. of starch (= 1.76 grms. of pure starch) dissolved in 250 grms. of water, were treated with 10 cc. of a solution, containing the gluten from 20 grms. of wheat flour dissolved in 130 cc. of a 1:1,000 solution of acid sodium phosphate, for 5 hours at 40°—50° C.; a liquid wort resulted capable of reducing 138 cc. of Soxhlet's solution of a copper salt in caustic potash; the complete saccharification of this quantity of starch by diastase would correspond to a reduction of 200 cc. of the solution. Albumen and gelatin under similar conditions only effect a slight saccharification of starch, whilst neither acid phosphate of soda, acetic acid nor hydrochloric acid in the dilute state employed for dissolving the gluten, have any solvent action on the starch. The vegetable albumen contained in wheat flour also acts like diastase. Solutions prepared by digesting wheat flour with acid phosphate of potassium are capable of converting starch into saccharine matter; this saccharification is aided by slightly acidifying the solution. Non-germinated barley also contains a constituent capable of saccharifying starch, and at a temperature of 50°—66° C. converts about two-thirds of the starch into soluble products. Here again the presence of small quantities of acid or of acid salts increases the action. The saccharification is best started at a temperature of 40°—45° C., and continued at 60°—66° C. A number of experiments with barley, malt and maize, as well as with mixtures of these, and employing solutions of acid sulphate of potassium, acid phosphate of potassium, acetic acid, and metaphosphoric acid are detailed. The saccharification of the starch of barley, maize, and wheat by the soluble ferments prepared as above forms the subject of a further series of experiments. The action is greatest in the case of barley, 50 to 86 per cent. of the contained starch being saccharified; the conversion is aided by the presence of potato starch.—C. A. K.

Saccharification by Diastase. L. Lindet. *Compt. Rend.* **108**, 453—456.

THE author cites experiments in confirmation of Payens' view that the secondary action of diastase upon the dextrins produced by the resolution of starch into maltose by dextrins is arrested by the accumulation of maltose in the solution,

and that during the alcoholic fermentation, as this maltose disappears, so the diastase continues its action on the dextrins until they disappear. O'Sullivan has attributed the saccharification of the dextrins during fermentation to the simultaneous action of diastase and yeast. The author, by using phenylhydrazine to precipitate the maltose from worts saccharified as far as possible by diastase, shows that in proportion as this precipitation takes place, the dextrins left in the solution undergo conversion into maltose.

PATENT.

Improvements in Apparatus for Use in Boiling and Evaporating Sugar and other Liquids. G. Fletcher, Litchurch, and C. A. Mathey, Demerara. Eng. Pat. 9183, June 23, 1888. 8d.

THE invention relates to vacuum pans, and consists, first, of a special arrangement of steam tubes which combine great efficiency in evaporating with special facilities for cleaning, and, secondly, of a special top or cover for the vacuum pan. The heating apparatus consists of two double series of horizontal tubes through which the steam circulates. For ease in cleaning operations, these sets of tubes are capable of being revolved on a horizontal axis into a vertical position. For the application of the special lid or cover the pan is made in two separate parts, the upper being large enough to slide loosely over the lower part in telescope fashion. Round the upper portion of the lower part is a copper trough into which the upper part of the pan loosely fits. The trough is filled with mercury, and when the pressure is reduced in the pan the mercury rises between the two telescoping parts of the pan. The lower part of the pan stands so high above the trough that at no diminution of pressure which is practically attained does the mercury rise high enough to get into the pan. Drawings are given.

—A. J. K.

XVII.—BREWING, WINES, SPIRITS, Etc.

Improvements in the Manufacture of Spirit. Dingl. Polyt. J. 271, 416—423.

ORDONNEAU (Rev. Univ. de la Dist. and Zeits. f. Spiritusind. 11, 183) has found the following substances in the first runnings of spirit made from molasses by fermentation with beer yeast:—Acetaldehyde, formic ether, isobutylaldehyde, acetic ether, and amylaldehyde. A small quantity of a body, heavier than water, and which gave the spirit a peculiar garlic-like odour, was also detected. The ill flavour of the spirit was due to the presence of valeraldehyde. The aldehydes are probably formed by a bacterial fermentation, during which the alcohols formed by the yeast are oxidised. This also explains the occurrence of the corresponding acids.

Yeast Poisons. H. Schultz (Zeits. f. Spiritusind. 11, 137).—Mercuric chloride in very dilute solution (1:500,000 to 1:700,000) considerably increases the activity of yeast for a shorter or longer time. Iodine (dissolved in potassium iodide) in all cases caused the fermentation to go on briskly from the beginning. The most favourable dilution was 1 in 100,000. Bromine has a similar effect when sufficiently dilute (1 in 300,000 to 1 in 400,000). Arsenious acid (1 in 40,000) has a favourable influence. Chromic acid (1 in 7,000 to 1 in 8,000) powerfully accelerates the initial activity of yeast. Salicylic acid (1 in 2,000 to 1 in 5,000) has likewise a favourable effect. Formic acid (1 in 300,000) temporarily increases yeast activity and causes fermentation to set in more quickly.

The Action of Acids on Yeast. Chapmann (Zeits. f. Spiritusind. 11, 232).—The quantity of sugar produced from starch-free yeast by the action of hydrochloric acid is

proportional to the concentration of the acid. The following percentages of sugar on the dry yeast were obtained:—

	Sugar.	Per Cent.
2 cc. of hydrochloric acid per 100 cc. of water.	2.6	
5 cc. " " " "	11.1	
10 cc. " " " "	16.3	
15 cc. " " " "	23.1	
20 cc. " " " "	24.9	
25 cc. " " " "	27.5	
30 cc. " " " "	29.3	

This sugar was produced almost entirely from the yeast cellulose.

Two Methods for the Removal of Pyridine Bases from Denaturated Spirit are described in the *Allgem. Zeits. f. Spirit. u. Presshefeind.* 9, 155.—According to W. Lang, such removal can be effected by shaking up the spirit with powdered zinc chloride; according to W. Kirchmann, by the addition of a solution of aluminium sulphate containing sufficient free sulphuric acid to permit of the formation of alum. In the first case, the pyridine is removed as zinc pyridine chloride, in the second, as pyridine alum.

—H. T. P.

Improvements in Brewing. Dingl. Polyt. J. 271, 461—472.

The Limit up to which Wild Yeasts may be Detected in Bottom Yeast. J. C. Holm and S. V. Poulsen (Zeits. f. d. ges. Brauwesen, 11, 381).—The experiments were made to determine the limits of temperature within which it is possible to work Hansen's spore-culture method. The yeasts examined were the Karlsberg bottom yeast, No. 2, and 18 other pure bottom yeasts. The wild yeasts added to these were *S. Pastorianus* I. and III. and *S. Ellipsoides*. The results showed that the 20 species of yeast tested by Hansen's method may be divided into two groups, of which one is best examined at 25° C. after 40 hours, and the other at 15° C. after 72 hours. In both cases a contamination with 1—1½ per cent. of wild yeast may be detected. Some members of the first group may also be analysed at 15° C.

Researches on the Physiology and Morphology of the Alcoholic Ferments. E. C. Hansen (Zeits. f. d. ges. Brauwesen, 11, 401).—The author's experiments were made with four different sugars: saccharose, maltose, lactose, and dextrose, and with nearly 40 species of yeasts, namely, with the six *Saccharomyces* described by Hansen in 1883, with *S. Marxianus*, *S. exiguus*, *S. membranifaciens*; 10 varieties of bottom yeast (*S. cerevisiae*), *Mycoforma cerevisiae*, *S. apiculatus*; seven varieties of Pasteur's *Torula*, *Monilia candida*, *Mucor erectus*, *M. spinosus*, *M. mucedo*, *M. racemosus*, and a few less known species of *Mucor*, and with *Oidium lactis*.

The results show that the *Saccharomyces* may be divided into two groups, according as they form invertin and produce alcoholic fermentation, or do not possess these properties. Only *S. membranifaciens* belongs to the latter class. All members of the first section form invertin in solutions of cane sugar and glucose, and produce active fermentation. Of the first class *S. Marxianus*, *exiguus*, and a few others do not ferment maltose, while the others do. Alcoholic ferments similar to yeast are next described (*Mycoforma cerevisiae*, *S. apiculatus*, *Torula*, *Monilia candida*). Like the *Saccharomyces* they all propagate by budding, but do not form endospores. Only one, *Monilia candida*, exerts a slight fermentative action on maltose. Many of them do not form invertin and have little or no fermentative action. A few varieties produce active fermentation in solutions of glucose and invert sugars, and as regards *Monilia candida*, the curious observation was made that it fermented cane sugar as such (without previous inversion). The *Mucors* are next considered. They also may be divided into two groups, according as they form invertin, or, as is mostly the case, do not form this ferment. Those members which exhibit a fermentative action also ferment maltose, if but slightly. Like the foregoing class, they differ considerably in fermentative power, and some cannot properly be considered as alcoholic ferments at all; to this latter class *Oidium lactis* belongs

As regards the industrial importance of the alcoholic ferments, the experiments show that only the genus *Saccharomyces* includes species which produce quick and active fermentation in solutions of maltose. In the manufacture of wine from grapes other organisms are available, since several of the *saccharomycetes*-like organisms produce fermentation in solutions of invert and grape sugars. The members of the genus *Mucor*, and also *Oidium lactis*, are of no industrial importance. As regards the behaviour of the four sugars towards the alcoholic ferments the following observations are made:—

1. There is nothing to show that invertin has any action on maltose; it must therefore be assumed that this sugar is directly fermentable, especially as a number of ferments which contain no invertin, such as *Monilia candida*, and all alcoholic ferments of the genus *Mucor*, except *M. racemosus*, have a fermentative action on maltose; *S. Maraschianus*, *exiguus*, &c., *S. apiculatus*, and the *Torulæ* do not ferment maltose. 2. Cane sugar is fermentable either without previous inversion (*Monilia candida*), or after inversion (most *Saccharomycetes*, a few species of *Torula*, and *Mucor racemosus*), *S. apiculatus*, a few *Torulæ*, and most of the *Mucors* have no action. 3. Dextrose is fermentable by all alcoholic ferments. 4. Lactose is fermented by only one species of ferment discovered by Duclaux in milk.

The Zymotechnical Analysis of the Micro-Organisms of the Air. E. C. Hansen (*Zeits. f. d. ges. Brauwesen*, 1888, 471).—By means of an aspirator a known volume of air is drawn through a small flask containing water, so that the organisms may be retained by the water. A "Miquel" flask is recommended for this purpose. Wort contained in small flasks is infected with this water. Hansen employs "Freudenreich" flasks, which are charged with about 15 cc. of sterilised wort. Only so much of the infected water must be added that the wort is not appreciably diluted. According to Hansen this method is suitable, not only for practical, but also for scientific purposes.—H. T. P.

Potato Culture. A. Girard. *Compt. Rend.* 108, 412—415.

THE alcoholic production of Germany is 4,000,000 hectolitres annually, three-fourths of which is obtained from the potato. France, whose distilleries produce only 2,000,000 hectolitres of alcohol, imports for the purpose 2,500,000 quintals of grain, chiefly maize, and appropriates 200,000 tonnes of sugar-beet, as well as 150,000 tonnes of beet molasses from the sugar refineries; the alcohol distilled from wine and cider amounts to only 100,000 hectolitres. In Germany, the cultivation of the potato has been so improved as to yield crops of 20,000—25,000 kilos. of tubers per hectare, with an average richness in starch of 17—18 per cent. In France, the crop seldom exceeds 10,000—11,000 kilos. per hectare, with a richness of 14—15 per cent. The author calculates that if by a proper system of cultivation crops of tubers can be grown in France, yielding 4,000 kilos. of dry starch per hectare, such crops are worth, to the distilleries, 800 fr. per hectare. By experiments extending over three years, with many different varieties of potatoes, and on two soils of very different richness, he has succeeded in 17 out of 29 trials in exceeding that yield. The best results were obtained with Richter's Imperator, which in 1888, a bad year for potatoes, yielded at one station 44,000, and at the other, 41,072 kilos. tubers per hectare, containing 18.4 and 19.5 per cent of starch respectively, equal to a yield of 8,096 and 8,000 kilos. dry starch per hectare.—J. M. H. M.

PATENTS.

Apparatus for Purifying Crude Spirit. W. S. Squire, London. Eng. Pat. 2735, February 23, 1888. 8d.

THIS invention has reference to an apparatus by means of which intimate admixture of the spirit with hydrocarbon oils and the subsequent separation may be effected continuously. The apparatus is somewhat like a filter-press, consisting of a series of chambers separated by channelled

plates or diaphragms. These plates are covered on both sides with filter paper supported on porous fabric. The tops and bottoms of each consecutive pair of plates are joined by means of passages which are connected to an injector nozzle that directs a stream tangentially into the chamber, thus causing its contents to rotate. Before starting the apparatus, all the lower filter-sheets are moistened with dilute spirit or water, and all the upper sheets with oil. Spirit is then pumped in at the top of the apparatus. When the chambers are partially filled, the inflow of spirit is stopped, and oil is pumped in at the bottom. The oil, in a finely-divided condition, floats up through the spirit, and takes up the impurities. Finally, the oil and spirit are separated, the oil passing through the upper filters which are soaked in oil, while the spirit passes through the bottom filters.—H. T. P.

Improvements in or Appertaining to the Clarifying of Beer, Wine, and other Fermented or Fermenting Liquids. A. G. Jericka, Gottlieben, and A. Eggmann, Ermatingen, Switzerland. Eng. Pat. 8522, June 11, 1888. 8d.

ACCORDING to this invention, turbid liquids are clarified by introducing into them porous blocks of baked clay or loam, or porous blocks of mineral of volcanic origin. These blocks can be used over and over again, and may be revived by calcination. A suitable shape is that of a hollow cylinder with corrugated surfaces. Particularly porous blocks may be obtained by mixing powdered burnt clay with moist clay or loam, and moulding and burning the mixture.—H. T. P.

Apparatus, Methods, and Arrangements adapted for Breweries, Distilleries, and other Installations for Charging Spaces or Chambers with Air free from Micro-organisms (Microbes) and their Germs, and preventing Air containing the same from penetrating therein and into Wort, and other Substances. K. Möller, Kupferhammer, Germany. Eng. Pat. 2110, February 6, 1889. 8d.

FOR the purpose of freeing air from germs, the inventor employs an apparatus, consisting of a number of conical filtering bags made of several layers of some closely-woven fabric. Each bag has placed in it a framework to prevent it from collapsing by air-pressure. The filters are placed in an outer case which is provided with an air outlet pipe. To this case is bolted a second case, also containing a number of filters which effect the preliminary cleansing of the air. This second case is fitted with air inlet and steam inlet pipes. In order to effect the preliminary sterilisation of the apparatus, steam is blown through it for about one hour. After this the filter is dried by passing a current of warm air through it. The outlet tap is provided with a test-cock, so that samples of the filtered air may be withdrawn and examined as to freedom from germs. To prevent the entrance of the outside air into the germ-free chambers, a slight excess of air-pressure must be maintained in them by forcing in filtered air. The chambers must be as air-tight as possible, and should be provided with valves to blow off at a certain pressure. The air supply pipe must be fitted with an arrangement to prevent the reflux of air when the pressure ceases. The air inlet and outlet pipes are provided with water closures so as to prevent the entrance of external air. The germ-free chambers are fitted with air-tight double doors, so arranged that the one can only be opened when the other is closed.

For filtering sterilised liquids an apparatus is employed, consisting of a number of filtering bags fixed inside a case which is fitted with an air-tight lid. This case is provided with inlet and outlet taps. The filters are cleaned by circulating boiling or sterilised water through the apparatus in an inverse direction. The apparatus is sterilised by blowing steam in at the liquid outlet.—H. T. P.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

On the Employment of Saccharine. P. de Clermont. Bull. Soc. Chim. 1889, 348—349.

THE author refers to some samples of cocoa containing saccharine instead of sugar which were presented to the Chemical Section of the Congress of the Swiss Society at Soleure by Schumacher-Kopp, the State chemist to the Canton of Lucerne. The analysis was as follows:—

	Per Cent.
Water (dried at 110°).....	3.89
Ash.....	6.45
Fatty matter.....	28.78
Phosphoric acid in the ash.....	16.88
Saccharine.....	6.76

This cocoa is much liked and used in Switzerland, and the author thinks it might with advantage be used by persons suffering from diabetes or obesity.

Numerous experiments have been made with it in the hospital at Lucerne, and no bad effects have been observed; on the contrary, in some cases its use has been attended with distinct advantages. The author thinks that the matter should be further studied, seeing that saccharine is prohibited in France but allowed in Switzerland, England, and other countries.—W. M.

So-called Congo Coffee. E. Fricke. Zeits. f. angew. Chem. 1889, 121—122.

THIS substance was obtained in a form resembling ordinary ground roasted coffee, but an infusion of it possessed an extremely astringent taste, and no caffeine or other crystallisable alkaloid could be found. A quantity of the natural bean was subsequently received, and this was found to be a species of *Phaseolus*, of shining black colour, and of such a size that 100 grms. contained 214 beans. The great difference in the percentage of woody fibre between the roasted material and the beans showed that a partial removal of the meal of the bean had been effected preliminary to the roasting process.—G. H. B.

PATENTS.

Improvement in the Treatment of Hide or Skin to obtain Gelatinous Matters. F. W. P. Swinborne and L. P. Swinborne, London. Eng. Pat. 9033, June 20, 1888. 8d.

ACCORDING to this invention hide or skin is thoroughly cleaved and then cut into thin shreds and dried. The shreds dry quickly and do not become tainted, so that they can be used for cooking purposes. If the hide has been limed or treated with a preservative, it must be well washed before drying. To obtain a superior product free from colouring matter and other impurities the hair and flesh sides of the skin are removed, and the middle portion only used. Instead of drying as above described the gelatinous matter is sometimes extracted from the middle portion with hot water, the solution being afterwards evaporated. Drawings are given showing the methods of cutting up and splitting the skin preferred by the inventors.—B. H.

Improvements in the Manufacture or Treatment of Gelatinous Substances. W. Gridley, London, and F. B. Pike, Streatham Hill. Eng. Pat. 2771, February 16, 1889. 4d.

THE object of this invention is the manufacture of a substitute for isinglass, called by the inventors "Isinglassine." To prepare it, the gelatinous material from calves' feet and other sources is thoroughly disintegrated and reduced to a pliable homogeneous mass. It is then passed between rollers to reduce the thickness, issuing from them in the form of white sheets or ribbons. After drying and pressing, the substance is cut into fine shreds by machinery, each pound being cut into about 125,000 shreds or staples.—B. H.

(B)—SANITARY CHEMISTRY.

The Purification of Sewage. Zeits. f. angew. Chem. 1889, 122—127 and 152—162.

A NOTICE of systems of sewage disposal at work in various continental cities compiled from official reports. The whole of the Berlin sewage is treated on the irrigation system, and to quote the main facts, the sewage of the year 1887—8 from 1,152,727 inhabitants amounted to 43,581,954 cubic metres, and was treated at a total cost of 0.526 mark per head of population. The average daily irrigation amounted to 3.77 litres per square metre of land, equal to a layer of sewage 3.8 mm. deep. Besides tables of general statistics relating to the system, the results of agricultural experiments on the irrigated land are referred to. The tables of analyses of the sewage and drainage waters give the number of germs present per cubic centimetre. The irrigation system was adopted in Breslau, as chemical treatment was too expensive. The cost is estimated at 1.25 marks annually per head. In Paris most of the sewage is sent into the Seine, but the adoption of a method of purification is now under consideration by the authorities. In Frankfurt the sewage is treated by chemical precipitation, and after clarification is sent into the river Main. Four subsidence reservoirs, each of 4,500 cubic metres capacity, are employed for the treatment of 18,000 cubic metres of sewage daily. The flow of treated sewage through these reservoirs is constant during eight days, at the end of which they are disconnected in rotation for removing the sludge, when the supernatant clear water is run off as far as possible, and the turbid water above the sludge proper is sent back to be mixed with the fresh untreated sewage. By this means the sludge is kept in as dense a form as possible, and is pumped into pits to drain. The reagents used are lime and sulphate of alumina, in quantities varying somewhat according to the state of the sewage. The cost is estimated at about 1 mark per head of population. At Wiesbaden the sewage is defecated by lime, and the drained sludge being in little demand as manure, is utilised for raising the level of the land near the works. In Essen the mode of treatment is by precipitation, at a cost of 0.62 mark per head. The writer concludes that the irrigation system is the most satisfactory where suitable land is available, otherwise chemical treatment is unavoidable.—G. H. B.

PATENTS.

Improvements in the Method or Process of and Apparatus for Purifying Sewage and other Impure Waters or Liquids. G. A. J. Schott, Bradford. From C. Lortzing, Berlin, Germany. Eng. Pat. 6070, April 24, 1888. 1s. 1d.

THIS specification describes a method of defecation of water-carried sewage by means of a mixture of quicklime, gypsum, and a metallic salt. The resulting sludge is settled out in a somewhat complex form of precipitating apparatus (described at length and illustrated in the specification) and then treated either with or without the use of steam or acid in filter-presses. The whole process and apparatus is covered by 26 claims.—C. C. H.

Improved Treatment of Materials for the Production of a Carbonised Body suitable for various Useful Purposes (Sanitary and other). E. Johnson, London. Eng. Pat. 6687, May 4, 1888. 6d.

GRANULATED dried ferruginous clay is mixed with an equal quantity of clean soot and tar, so as to form a thick mortar. The mixture is granulated and the whole carbonised in closed retorts, and thus rendered suitable for filtering purposes. If used as a deodorant or decoloriser, it is subjected to the action of pure oxygen in a closed receiver; if for disinfecting, chlorine is used instead of oxygen; and if for fertilising, soluble phosphates or other fertilisers may be added.—C. C. H.

Improvements in the Prevention of the Pollution of Rivers and Watercourses from Manufacturers' Polluted Waters and Waste, and for Clearing and Purifying ordinary River Waters for the Use of Manufacturers in their Business and for the Recovery of Expensive Materials used in certain Trades, as in Paper Mills, Dye Works, and others. W. Edwards, London. Eng. Pat. 8371, June 7, 1888. 8d.

A TANK is divided into separate compartments, each of which consists of an upper and a lower part. The upper portion is packed with a filtering material consisting of sand, coke, or gravel, resting on a perforated bottom and covered on top with cocoa-nut matting. The lower part of the tank forms a receptacle for filtered liquid and communicates through an opening controlled by a sluice with another chamber from which the liquid may be drawn by means of siphons or steam ejectors, and so an increased rate of filtration obtained.—C. C. H.

XIX.—PAPER, PASTEBOARD, Etc.

PATENTS.

Improvements in the Production and Manufacture of Paper having Waterproof, Non-conducting, and other Valuable Properties and Qualities. T. J. Pearce and M. W. Beardsley, Oakland, California. Eng. Pat. 3787, March 12, 1888. 6d.

THE INVENTORS saturate paper with "Maltha," which is the solid residue from the distillation of the heavier grades of petroleum.—E. J. B.

Process for Denitrating and Dyeing Pyroxilin. Le Vicomte Hilaire de Chardonnet, Besançon, France. Eng. Pat. 5270, April 9, 1888. 4d.

THE PROCESS consists in treating nitrocelluloses with nitric acid of a density of 1.32, whereby, in a few hours, they lose part of their nitrogen and become reduced below the state of the "tetranitrate," at the same time beginning to soften and being rendered more easy of treatment in dyeing and other operations.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Reduction of Tartaric Acid. M. Ballo. Ber. 22, 750—754.

IF one part of tartaric acid be heated on the water-bath with one-tenth part of crystallised sulphate of iron, a greyish yellow precipitate is formed. The mass, evaporated to crystallisation and extracted with alcohol, yields on evaporation of the alcoholic extract a residue which has acid properties. It combines with lime to form a lime salt. The author calls the acid *Iso-arabismic acid*. It may be isolated from the lime or lead salt by precipitating the base as oxalate or sulphide respectively. It has the composition $C_6H_8O_6$. It has no action on Fehling's solution, but turns the plane of polarisation to the right. It is a monobasic acid forming salts of the general formula $C_6H_7O_6M$. A second substance, *iso-arabismic hydrate*, is formed in this reaction, of the formula $C_6H_{12}O_6$. The greyish-yellow precipitate above mentioned is an organic compound containing 14.2 per cent. of iron. The object of the above research, as the author explains, is to show the possible action of iron in inducing organic change such as is ascribed to the iron present in chlorophyll.—J. B. C.

Constitution of the Cinchona Alkaloids. Z. H. Skraup. Monatsh. Chem. 10, 39—50.

THE author has recently shown that the "second half" of cinchonine contains a nucleus which is certainly not a quinoline ring but is in all probability a piperidine ring, and this view is in accordance with what is already known of the behaviour of cincholoipon and cincholoipic acid. Quinine, when oxidised with chromic acid, yields, as is already known, quinine acid, $C_{11}H_9NO_3$, and syrupy products which are analogous to those obtained from cinchonine and which can be separated into two portions by saturating the syrup with bases and extracting with alcohol. The portion insoluble in alcohol consists of salts of quinine acid, triarabopyridinic acid and an amorphous nitrogenous acid which hitherto could not be obtained in a pure state. The last-named acid can, however, be easily prepared in a crystalline condition by oxidising chitenine, $C_{19}H_{22}N_2O_4$, which, as the author has previously shown, is formed together with formic acid when quinine is carefully oxidised with potassium permanganate. Chitenine, prepared as previously described, when crystallised from alcohol, generally contains an impurity which can be removed by dissolving in warm ammonia, saturating the solution with carbonic anhydride, and repeating the process. It has no well-defined melting point, but generally melts at about 265° when heated slowly. It does not combine with phenylhydrazine, but it yields an amorphous yellowish-red acetyl-derivative. It is reduced when treated with sodium amalgam in dilute sulphuric acid solution yielding an amorphous base, the aqueous solutions of which are intensely yellow coloured. It yields an amorphous compound when treated with potash and ethyl iodide, and when heated with hydrobromic acid it is converted into the hydrobromide $C_{19}H_{22}N_2O_4 \cdot 2 HBr$.

Oxidation of Chitenine.—The most important product of the oxidation of this substance by chromic acid (about 25 per cent. of the chitenine employed) consists of cincholoipic acid, the isolation of which is described in detail. This acid is obtained in the form of a syrup which could not be induced to crystallise, but when agitated with a little warm hydrochloric acid and a crystal of cincholoipic acid hydrochloride (from cinchonine) thrown into the cold mixture, the hydrochloride, $C_{11}H_{13}NO_4HCl$, separates in well defined prisms or in small crystals according to the concentration of the solution; further quantities of the salt can be obtained from the mother-liquors by converting into the lead salt, purifying the latter by repeatedly precipitating with alcohol, decomposing with sulphuretted hydrogen, and treating the resulting syrupy acid as described above. The cincholoipic acid and the hydrochloride thus obtained are identical in chemical, physical, and also in optical properties with the corresponding compounds obtained from cinchonine. It was also proved that from the mixture of neutral compounds which are formed when quinine is oxidised with chromic acid a compound can be isolated which is identical with cincholoipon obtained by oxidising cinchonine.

If cincholoipic acid is heated for a short time on the water-bath it loses the power of crystallising, and is precipitated in an amorphous condition when alcohol is added to the aqueous solution; even after dissolving in hydrochloric acid the salt does not crystallise until after some weeks. This fact explains why in former experiments cincholoipic acid and its hydrochloride were not obtained in a crystalline condition.

Cincholoipic acid is best prepared as follows:—55 grms. of commercial quinine sulphate are dissolved in 30 grms. of concentrated sulphuric acid, the solution made up to 500 cc., and each 100 cc. is mixed in the cold with 380 cc. of a 4 per cent. solution of potassium permanganate. After filtering from the manganese oxide the filtrate and washings are evaporated to about 1½ litres; the concentrated solution of chitenine thus obtained is heated on the water-bath and a solution of 80 grms. of chromic acid and an equivalent quantity of sulphuric acid is gradually run in. When oxidation is at an end the whole is poured into excess of potash, boiled, filtered, the filtrate neutralised with sulphuric acid, and the potassium sulphate allowed to separate as completely as possible. The mother-liquors are mixed with a large volume of alcohol, concentrated sulphuric acid added,

and the whole vigorously shaken until the precipitate becomes colourless and crystalline. The alcohol is evaporated, the solution boiled with excess of lead carbonate, filtered, concentrated, and the residual lead salt precipitated three or four times from its aqueous solution with alcohol, decomposed with hydrogen sulphide and the filtrate acidified with hydrochloric acid and concentrated. On adding a crystal of the salt, cincholoipic acid (4—5 grms.) separates, and further quantities can be obtained from the mother-liquors, as well as from the lead salt which remains in solution after precipitating with alcohol. This method is also recommended for the preparation of cincholoipic acid from cinchonine.

The author's investigations prove that the "second half" of quinine has the same constitution as that of cinchonine, so that the chemical difference between these two alkaloids is simply this, that quinine is a derivative of paramethoxyquinoline whilst cinchonine is a derivative of quinoline itself. The manner in which the two nuclei are joined together may, however, differ in the two alkaloids. The further investigation of cincholoipon and cincholoipic acid will be of importance in ascertaining the constitution of quinine.—F. S. K.

Constitution of the Cinchona Alkaloids.

H. Schnüderschütz, *Monatsh. Chem.* **10**, 51—64.

The isomeric alkaloids cinchonine and cinchonidine are very similar in properties and in their behaviour towards reagents. When carefully oxidised with potassium permanganate they both yield formic acid and are converted into cinchotenuine and cinchotenidine respectively; these two compounds have the composition $C_{17}H_{19}N_2O_3$, and both contain a hydrogen atom replaceable by the acetyl-group. Cinchonine and cinchonidine both yield cinchoninic acid when treated with chromic acid; this fact proves that both compounds are quinoline derivations, and that the hydroxyl-group must be situated in that portion of the molecule which is converted into cinchoninic acid. Comstock and Königs showed that the difference in constitution between these two alkaloids must be very slight, as they can be both made to yield one and the same cinchotenidine.

When cinchotenine or cinchotenidine is oxidised with chromic acid cincholoipic acid is obtained in a crystalline condition. An aqueous solution of cinchotenidine, prepared by oxidising cinchonidine with 4 per cent. potassium permanganate solution, was treated with chromic acid as described by Skraup (preceding abstract). Cinchoninic acid and an acid identical with cincholoipic acid from cinchonine were obtained, and as apparently no other product was formed the decomposition seems to take place in accordance with the equation—

The formation of cincholoipic acid is a further proof that the difference in constitution between cinchonine and cinchonidine is extremely slight, and that in addition to the points noticed above which these two alkaloids have in common, they both contain one and the same complex consisting of eight carbon atoms which, on oxidation, yields cincholoipic acid, and is, in all probability, a piperidine derivative. It may be that both alkaloids contain the same two constituent groups, and that their isomerism, if not purely physical, is due to some slight difference in the manner in which the two nuclei are combined together. If a compound identical with cincholoipon (from cinchonine) could be obtained from the nucleus in cinchonidine which is not oxidised to cinchoninic acid this view would be proved to be correct.—F. S. K.

Constitution of the Cinchona Alkaloids. J. Würstl. *Monatsh. Chem.* **10**, 65—72.

QUINIDINE, $C_{20}H_{21}N_3O_2$ (conquinine), is isomeric with quinine, and, like the latter, it forms salts which give fluorescent solutions. Skraup (*Annalen*, **199**, 340) has previously shown that quinine and quinidine are both oxidised by potassium permanganate, yielding formic acid and a base, $C_{19}H_{20}N_2O_4$.

This decomposition shows that one of the 20 carbon atoms is similarly situated in both alkaloids.

Quinine and its first oxidation product, chitenine, when treated with chromic acid, yield, as has been shown by Skraup, quinic acid and an acid syrup from which cincholoipic acid can be isolated.

The author treated an aqueous solution of chitenidine, prepared by oxidising quinidine sulphate with a 4 per cent. solution of potassium permanganate with chromic acid solution, as described by Skraup (preceding abstract), and obtained quinine acid and a cincholoipic acid identical with that formed from cinchonine, quinine, and cinchonidine. This fact proves that chitidine and quinine are both derived from a paramethoxyquinoline, and that the quinoline ring containing the methoxy-group is joined to the rest of the molecule in the same way as in quinine. In neither base can the hydroxyl-group be situated in that portion of the molecule which is oxidised to quinine acid, and both alkaloids contain the same complex, consisting of eight carbon atoms, to which the formation of cincholoipic acid is to be ascribed. The difference between the two alkaloids must, therefore, be due to a difference in constitution of the complex which does not yield quinic acid, and this difference, cannot be greater than that between cinchonine and cinchonidine.

In determining the relation between the four cinchona alkaloids, it will be of great importance to ascertain whether a compound analogous to cincholoipon (from cinchonine and quinine) can be obtained from cinchonidine and quinidine.—F. S. K.

Morphine. Skraup and Wiegmann. *Monatsh. Chem.* **10**, 101—114.

V. GERICHTEN, Schrötter, and O. Fischer have proved that morphine, $C_{17}H_{19}NO_3$, is a derivative of phenanthrene, $C_{15}H_{13}$, but the results of investigations on the decomposition of the alkyl-derivatives of morphine are very contradictory. v. Gerichten and Schrötter (*Ber.* **15**, 2179) observed that when methylmorphinemethylhydroxide is heated, a phenanthrene derivative, $C_{15}H_{13}O_2$, and methylethylpropylamine are obtained, a result which would seem to prove that the nitrogen atom was combined with a propyl-group. Hesse (*Annalen*, **222**, 232), on the other hand, found that methylmorphinemethylhydroxide yields trimethylamine, and not dimethylpropylamine, as was to be expected from v. Gerichten and Schrötter's investigations.

The authors found that when morphine is heated at a high temperature with alcoholic potash, sodium ethylate or sodium amylate, a volatile amine, and a phenol-like compound are obtained. When amyl alcohol is employed, considerable quantities of piperidine are often produced, owing to the presence of pyridine in the commercial amyl alcohol. The method which was found to give the largest yield of amine was the following:—Morphine is mixed with 10—15 times its weight of a 20 per cent. solution of alcoholic potash, and heated at 180° for 4—6 hours, the whole operation being carried out in absence of air. The dark-brown product is poured into dilute sulphuric acid, filtered from a light-brown flocculent substance, the filtrate saturated with soda, distilled with steam, and the distillate collected in hydrochloric acid of known strength.

The light-brown flocculent substance is very unstable, and rapidly darkens on exposure to the air. It is very difficult to purify, but it can be obtained in colourless microscopic crystalline flocks by repeated fractional precipitation (with water) from its solution in warm dilute alcoholic sodium hydrogen sulphite. It has the composition of a dihydroxy-morphine, $C_{17}H_{19}NO_5$, but all attempts to investigate this compound more fully were unsuccessful. When carefully oxidised with ferric chloride, it is converted into a red, unstable compound.

The quantity of the amine produced was, on the average, 40 per cent. of the morphine employed. It has the composition C_3H_7N , and was proved to be ethylmethylamine by direct comparison of the bases themselves and several of their salts, all of which were prepared and are fully described.

Ethylmethylamine, C_3H_9N , is a colourless liquid boiling at 34° – 35° . The *hydrochloride* is a colourless, hygroscopic crystalline compound melting at 133° . The *platinchloride* crystallises in needles melting at 208° ; the *aurochloride* melts at 179° – 180° .

The formation of ethylmethylamine shows that the nitrogen atom in morphine is directly combined with two alkyl-groups, so that it can only be combined with the phenanthrene complex with one affinity. Knorr's research (Ber. 22, 181, this Journal, 1889, 305), on the other hand, leads to the conclusion that the nitrogen atom is only combined with one alkyl-radicle. The formation of trimethylamine from methylmorphine-methylhydroxide could be explained by assuming that the ethyl-group is split off as ethylene, but it is difficult to understand how it is that Knorr obtained only dimethylamine from methylmorphine and not dimethylethylamine, as was to be expected from the authors' results. Some of the most important parts of this research were repeated, and it was found that ethylmethylamine is obtained, free from any considerable quantity of other amines, even when the alcohol employed is previously distilled over oxalic acid. This base is also produced when morphine or codeine is heated with methyl alcoholic potash. There can, therefore, be no doubt that morphine contains both a methyl- and an ethyl-group in direct combination with the nitrogen atom.

In the above experiments two samples of morphine, from different provinces, were examined, and both gave the characteristic reactions for this alkaloid. One sample was converted into morphinemethyl iodide and the product showed all the properties of this compound; in preparing other morphine derivatives the authors experienced considerable difficulties which at the time were attributed to chance, but whether such is really the case further investigations must decide.

Normal propylamine undergoes no change whatever when heated with alcoholic potash under the same conditions as those described above in decomposing morphine.—F. S. K.

Report on New Drugs and Fine Chemicals. Merck's Bull. 2, 13–20.

Acetyl-phenylhydrazine (C_6H_5)HN.NH(CO.CH₃). ("Pyrodine").—This body, first synthesised on a basis of theory by A. S. Liebmann, and as "Pyrodine," therapeutically examined by Dreschfeld (this Journal, 1888, 765), was first commended by the latter, but subsequently in communications to Liebreich, he added a caution as regards the toxic action of the drug. Lepin has since confirmed this latter observation and the need of caution required (Lyon méd. 1888, No. 80). Merck has now observed that the risks of toxic action reside in the fact that, as hitherto prepared, the substance is of variable nature, and that toxic action is due to impurities.

Pieric Acid.—This substance has been recently employed with success in the treatment of *Eczema impetiginosum*, by Cerasi (Gazzetta med. di Roma). Solutions of 0.3 to 0.6 per cent. strength are used.

Benzanilide, $C_6H_5NH.CO(C_6H_5)_2$.—A derivative of benzoic acid and aniline, just as acetanilide is of acetic acid and aniline. Its therapeutic properties are similar to those of acetanilide. E. Kahn (Wiener med. Wochenschrift, 1888, 1523) found it to be "a powerful and well-borne antipyretic." Febrile temperatures were reduced by some degrees within an hour, after a small dose as 0.2 gm.

Curarine.—The active principle of curare (arrow poison). Prepared according to Böhm's method *curarine* appears as a yellowish-brown, amorphous, hygroscopic powder of intensely bitter taste. It is easily soluble in water and in alcohol, but insoluble in ether. It shows no perceptible alkaline reaction and forms no true salts, but decomposes on being heated with mineral acids, forming a crystalline derivative which has not yet been investigated. Concentrated sulphuric acid dissolves *curarine*, producing a crimson colour, which on addition of a little potassium bichromate, passes into a bluish tint. The strength of the preparation (*curarine*) may vary, just as in the case of curare, according to the origin of the crude drug from which it is prepared.

Lithium salicylate is pronounced by Vulpian to be of greater effect than sodium salicylate in gout and acute articular rheumatism. He maintains that the lithium salt is capable of consummating the action of the sodium salt.

Beta-naphthol.—Bouchard recommended this as a very slightly toxic but efficacious intestinal disinfectant. More recently, the experiments of Reverdin (Soc. Med. de la Suisse romande) have fully confirmed this, and also shown it to be an excellent surgical antiseptic. In surgical cases the naphthol is presented either in powder or in 10–15 per cent. wadding, which is prepared by sterilising cotton wadding at 130° C., and then impregnating it with an ethereal solution of beta-naphthol. Ruault has employed beta-naphthol water with good effect in ozæna. This solution is prepared by dissolving 125 parts by weight of the naphthol in 88 of alcohol and stirring 15 to 20 cc. of this into a quart of water.

"*Pyrofusine*."—This is the name of a peculiar ulmin-like substance extracted from various kinds of bituminous coal by treatment with alkaline solutions. In alkaline solution, a very strong antiseptic action is developed. P. F. Reinsch discovered this substance, and has applied it in his new process to the tanning of leather. The cellular structure of animal skins becomes so altered that an excellent leather is produced after a very brief immersion in a pyrofusine solution.

Amido-saccharine or *Paramidobenzoylsulphonic imide*.—This is a sweetening agent closely related to saccharine—

Its discoverer is A. Noyer. The amide is but little soluble in cold water, and a solution of it in hot water exhibits a deep blue fluorescence, and possesses an intense and persistent sweet taste.

Artificial Borneol, $C_{10}H_{18}O$, as obtained from rosin (colophony) by Armstrong and Fielden, is so far chemically undistinguishable from the native or true borneol or Borneo-camphor. Its alcoholic solution is, however, optically inactive, and this is the only property which serves to distinguish it from the natural product, the solution of which is dextro-rotatory. Borneol resembles the officinal or laurel camphor in its appearance, and consists of leafy white crystals. It is heavier than water, whilst common camphor is lighter. Its melting point is 199° C. In the case of frogs, it acted like laurel camphor in reducing the pulse-rate, but the pulse became fuller at the same time. In addition, however, R. Stockman finds, in the case of the artificial product, that a paralysis of the pneumo-gastric nerve is induced, not observed in that of the common camphor.

Butyl Chloral Hydrate, $C_4H_9Cl_3O$ + aq., or *Hydrate of Normal Trichlorobutylaldehyde*.—For some years after its discovery in 1870 was known as croton chloral hydrate. This is a misnomer, though still largely adopted, since it really applies to the substance of the formula $C_5H_9Cl_3O$ + aq. The subject of this note is a valuable anodyne in cases of special neuralgia, facial rheumatism, perioritis, &c. Liebreich prepares the composition recommended, so as to avoid the unpleasant taste of the butyl compound, as follows:—Butyl chloral hydrate 2–3–5 grms.; alcohol, 10 grms.; glycerol, 20 grms.; and distilled water, 120 grms.

Creatine.—Methyl-glycoeyamine—

in the anhydrous state forms an opaque, white, solid inodorous substance possessing a somewhat bitter acid taste. Its monohydrate crystallises in clear prisms, losing their water of crystallisation at 100° C. Creatine is soluble in about 70 parts of water, but almost insoluble in absolute alcohol. Creatine is one of those constituents of meat soups and extracts which impart appetising taste and stimulating action to the heart and muscular centres. Th. J. Mays has shown that creatine solutions as weak as 1:2,000 are

capable of re-animating a frog's heart which has been fatigued, and finally arrested by administration of sodium chloride. Robert (Chem. Zeit. 1888, 1662), as the result of experiment, recommends this principle as of undoubted value as an excitant of muscular action, in the case of the heart, digestive organs, and general muscular system.

Ethyl Bromide has gained renewed favour as an anæsthetic in light surgical practice, obstetrics, &c. Emphatic warning is given against substitution of *Ethylene bromide*, which has in several cases been erroneously supplied and administered. In the latter case, vomiting, great pallor, cerebral pain, and *tinnitus aurium* supervene. *Ethyl bromide* boils at 38° to 39° C., and when properly made is obtained by distillation of a mixture of potassium bromide, pure alcohol, and sulphuric acid, with purification of the crude product. *Bromide of Ethylene* boils at 131° C., and has no anæsthetic power whatever.

Lantaine is an alkaloid recently discovered by Boniza and Negrata (Chem. Centr. 1888, 1620) in the plant *Lantana brasiliensis*, called by the Peruvians "*Yerba Sagrada*." It acts similarly to quinine as an antipyretic, is well borne even by very weak stomachs, and proves of great efficacy in intermittent fevers in cases where quinine has been resisted.

Solanine.—This is a basic glucoside capable of forming true salts with acids, and also of being fractionated into a glucose and another substance of peculiar properties—"*Solanidine*." Solanine is contained in widely different species of the *Solanum* family, but is chiefly obtained from the sprouts of the potato (*Solanum tuberosum*). It forms colourless, lustrous, fine needles, melting at 235° C., is nearly insoluble in water, ether, and benzene; little soluble in cold, easily so in hot alcohol. Taste slightly bitter and pungent.

Solanine is an excellent neurotic sedative, more efficacious in long standing neuralgia, especially when neuritis is present, than either antifebrin or antipyrine. (Sardas, Bull. gén. thérap. 1888, May 30.) The solanine salts are easily soluble in water.

Urechites faberecta is the name of a plant found in Jamaica, containing two very poisonous glucosides, *Urechitin*, $C_{22}H_{42}O_{10}$, and *Urechitorin*, $C_{13}H_{26}O_5$. The former is obtained in the form of needles of intensely bitter taste and almost insoluble in water, but easily soluble in hot alcohol. Miniewicz (Dorpat, 1888) has recently isolated from the same plant an amorphous glucoside and an acid resin, both highly toxic. *Urechites* appears to be closely related in its effects to strophanthus, and is also an antidote to curare.

Viburnin, an extract from the bark of *Viburnum prunifolium* or "Black Haw," has been found of great value in certain uterine affections, especially by American physicians. Debrierte (Nouveaux remèdes, 1888, 396) has prepared the first precise report on the extract and his experiment with the active principle of the bark, *Viburnin*. There is room for still further research in view of the important results attained, with what must still be regarded as a crude product.—W. S.

PATENT.

Improvements in the Production of Iodine and Iodine Compounds. H. Suilliot and H. Raynaud, Paris. Eng. Pat. 9166, June 23, 1888. 6d.

THE solution of kelp, or any other liquid containing iodine in the form of iodides, is made alkaline by addition of sodium hydroxide, mixed with an excess of acetone, and a dilute solution of a hypochlorite is added gradually. Iodoform separates as a curdy precipitate, and the addition of the hypochlorite is continued until the formation of a precipitate ceases. Practically the whole of the iodine separates in the form of iodoform, from which it is recovered by any of the ordinary processes. Sulphides, sulphites, and thiosulphates reduce a certain quantity of hypochlorite, but other alkaline salts do not interfere. The hypochlorite may be replaced by any substance which will form a hypoiodite by reaction with an iodide.—C. H. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

New or Improved Process for the Production of Coloured Photographs upon Glass and like Substances. A. E. Lottale, Balsall Heath, and F. Billing, Birmingham. Eng. Pat. 8518, June 11, 1888. 6d.

A glass plate is coated with a film of gelatin sensitised with a chromium compound as in the ordinary process of carbon printing. The film is exposed to light under a transparent positive image, and the chromium salts which remain soluble are removed by washing with water. The plate and film are then dried and afterwards immersed in a solution of some dye containing about 50 per cent. of glycerol. It is found that the dye attaches itself only to those parts of the film which have not been acted upon by light. The film is immersed in a solution of alum, then dried.

Gelatin films sensitised with ferric chloride and tartaric acid may also be used, and are dried at about 50° and exposed under a negative. In this case the dye solution is made by dissolving the dye in water or dilute alcohol, with or without admixture of glycerol, gum, or similar substances.—C. H. B.

Improvements in Apparatus for Producing and Discharging Currents for Washing Photographic Plates and Prints or other Analogous Purposes, capable of being attached for use upon or to any ordinary Vessel. W. Tylar, Birmingham. Eng. Pat. 9711, July 4, 1888. 8d.

THE apparatus consists essentially of a metal syphon which may be hung on the edge of any vessel. That limb of the syphon which is in the vessel is divided into two compartments, one of which is in communication with the discharging limb outside, whilst the other is connected with a water supply by means of which a current of water may be sent into the vessel under any desired pressure. The lower part of this feed pipe is provided with angular openings which send the water in different directions and thus promote constant circulation. Baffle plates may be used if necessary in order to still further divide the current. At the top of the syphon is a valve by means of which the current of water can be sent into the vessel down the feed pipe, or else down the discharge pipe. In order to start the syphon the water is first sent down the discharge pipe until all the air is drawn from the syphon, and if the valve is now turned and the water is sent along the feed pipe the syphon continues to act and draws off the surplus liquid from the vessel. Instead of dividing a limb of the syphon a separate feed pipe may be permanently attached to it. The inlet and outlet tubes may be closed with metal gauze, perforated plates, or any similar substance.—C. H. B.

Improved Apparatus for Washing Photographic Negatives and Prints. F. Bishop and D. Allan, London. Eng. Pat. 4103, March 8, 1889. 6d.

AN ordinary washing trough provided with the usual inlet and outlet tubes has standards attached to the ends or sides, and on these slides a rack in which the plates are held corner-wise in the ordinary manner. By means of clamping screws the rack can be adjusted at any height in the trough, and when the plates are completely washed the rack can be raised out of the water and is supported directly over the trough whilst the plates drain.—C. H. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENTS.

Improved Safety Smokeless Gunpowder. C. F. Hengst, Plumstead. Eng. Pat. 13,656, September 21, 1888. 6l.

This powder is produced by nitrating pulped straw, and after removal of all traces of acid, granulating the product with or without the addition of oxidising agents.—C. N. II.

Improvements in the Manufacture of Explosive Compounds. J. W. Skoghund, Stockholm, Sweden. Eng. Pat. 18,362, December 15, 1888. 6d.

This invention relates to the manufacture of explosive compounds, consisting of nitro-cellulose or trinitrophenol together with the radicle of carbonic, oxalic, or carbamic acids, in combination with ammonium, or another volatile radicle base, or hydroxyl.—C. N. II.

XXIII.—ANALYTICAL CHEMISTRY.

Action of Sulphurous Acid on Alkaline Hyposulphites. A Correction. A Villiers. Comp. Rend. 108, 402—403.

THE salt obtained by the action of sulphurous acid on hypsulphite (thiosulphate) of soda, and previously described by the author as having the formula $\text{Na}_2\text{S}_2\text{O}_4$, i.e., the sodium salt of a new acid, proves, on further examination, to be hydrated sodium tetrathionate, $\text{Na}_2\text{S}_4\text{O}_6 \cdot 2\text{H}_2\text{O}$. The salts formed in the reaction are therefore sodium trithionate and tetrathionate, $2\text{Na}_2\text{S}_2\text{O}_4 + 3\text{SO}_2 = \text{Na}_2\text{S}_3\text{O}_6 + \text{Na}_2\text{S}_4\text{O}_6$. —J. M. H. M.

The Free Caustic Alkali of Soap. J. A. Wilson. Chem. News, 59, 280.

THE author has already pointed out that there is a source of error in the spirit method, and this error is due to the simultaneous presence of free alkali and free fat or oil.

When high class soaps are analysed, containing no free glycerides, the spirit method gives very accurate results; but any analyst who has to deal with soaps of any quality, and made in the most imperfect manner, will find the alcohol process perplexing. Hence, the author has no hesitation in saying that the determination of free caustic alkali in some soaps is one of the *most difficult problems* met with in practice. The conditions necessary to ensure the stability of the soap (i.e., the decomposition into an acid soap and free caustic alkali) are just those conditions necessary to ensure the absolute saponification of the glycerides by the *free caustic alkali present*. To any expert in soap analysis, the presence of free alkali and glycerides in the sample simultaneously is easily seen; on the addition of alcohol with phenolphthalein the colour goes deep, then gradually fades and may disappear altogether.

The method depending on insolubility of soap in strong brine has been proved to give the most inaccurate results, whilst that depending on precipitation of the alkali by carbonic dioxide gas, the solvent for the soap being alcohol, gives the same conditions necessary for complete saponification, as stated above; hence, this process is of no use. It is necessary to bear these facts in mind in these days, when we hear so much about the absence of free alkali in certain soaps.

In using the alcohol process for determining free caustic alkali, it is necessary to use nearly, or, better, absolute alcohol, and to conduct the operation with the least possible access of air. Moreover, the alcohol should be used largely and in due regard to the percentage of water in the soap.

In these cases, on account of the presence of free fat, the alcohol process must be abandoned if good results are required, and it will be better to state the results in this form:—

Alkali in total, per cent. Alkali combined with fatty acids, per cent.

If the alkali existing as silicate and carbonate be very carefully determined, some idea may be gained of the alkali actually present as sodium hydrate. Supposing palm-nut or cocoa-nut oil to have been used in the fabrication of the soap, the determination of the Na_2O required to neutralise the fatty acids becomes quite inaccurate, owing to the solubility of the lower fatty acids; hence, another complication arises.

In order to show the differences between the above methods, a few analyses may be quoted:—

Nature of the Sample.	Alkali (Na_2O) by Titration.	Alkali by Titration of the Insoluble Fatty Acids.	Alkali by Alcohol Test.
	Per Cent.	Per Cent.	Per Cent.
1. Palm-oil soap, cold process	5.00	4.59	0.00
2. Highly watered soap from bone-fat.....	3.51	0.71	0.31
3. Palm-oil soap, similar to No. 1.....	5.61	5.39	0.00
4. Common soap for calico-printers.....	6.05	6.31	0.33
5. Soap from tallow and cocoa-nut oil.....	3.53	2.52	0.107
6. Washing soap sold in North of England.....	7.33	7.70	0.017

The article sold for calico-printers' use, known as soluble oil, which is made from castor oil, consisting therefore of the sodium salt of ricinoleic acid, is required to be as neutral as possible; hence some makers, after saponification, add hydrochloric acid to neutralise the excess of alkali, which of course is overstepped, and free fatty acid results. Its usual composition is—

	Per Cent.
Free fatty acid as ricinoleic acid	4.75
Total fatty acids.....	20.50
Total alkali.....	1.67

On decomposition of this soap with subsequent titration of the washed fatty acids the number of cc. of alkali used for neutralisation must be corrected by that required to neutralise the free fatty acids. Samples No. 1 and 3 in the table contained matured glycerides easily detected as previously mentioned. That the figure 0.31 per cent., corresponding to soap No. 2 is incorrect was proved by estimation of the carbonate and silicate in the soap. The last soap in the table actually gave results higher in the third column than in the total column.—W. S.

Determination of Lithium as Fluoride. A. Carnot. Bull. Soc. Chim. 1889, 280—286.

THE fluorides of potassium, caesium, and rubidium are readily soluble in water; the solubility of sodium fluoride in water is 1:25, whilst that of lithium fluoride is 1:800 at ordinary temperatures. In a mixture of equal volumes of water and ammonia the solubility of lithium fluoride is only 1:1,900, whilst in presence of a little ammonium fluoride the solubility is further decreased, being then 1:2,100 water, 1:3,000 a mixture of three volumes of water to one volume of ammonia, and 1:3,500 a mixture of equal volumes of ammonia and of water. The solubility of sodium fluoride in this last mixture and in presence of ammonium fluoride is 1:70.

The method proposed by the author for the determination of lithium and for its separation from sodium and potassium is based upon the slight solubility of its fluoride in presence of ammonia and ammonium fluoride. The solution containing the mixed salts of the three alkalis, in which the proportion of sodium plus potassium to lithium should not be greater than 10 or 15 to 1, is evaporated down to a few cc. in a weighed platinum dish and treated with fluoride of ammonium and an excess of ammonia. [The ammonium fluoride must be free from fluosilicate; to remove the latter dissolve the fluoride in water, add double the volume of ammonia, boil for a few seconds, allow to cool and filter off the separated silica. The solution can be kept for several days in a stoppered glass bottle.] The mixture is well agitated and allowed to stand for 24 hours, when a white gelatinous precipitate of lithium fluoride separates, which adheres partially to the dish. This is washed 2—3 times by decantation with water containing both ammonia and ammonium fluoride, and the washings filtered, the portion of the precipitate collected on the filter-paper being again washed with the above mixture. The filter is then dried, burned, the residue dissolved in dilute sulphuric acid, and the resulting solution added to the portion of the original precipitate in the platinum dish, the whole of the lithium being thus finally obtained and weighed in the form of sulphate. The solubility of the lithium fluoride in the ammoniacal mixture is allowed for, after measuring the volume of the filtrate (this ranges from 30—50 cc.), as follows:—7 cc. of the filtrate dissolve 0.002 gm. of lithium fluoride corresponding to 0.004 gm. of sulphate and to 0.001 gm. of metallic lithium. The separation of potassium and sodium can be effected in the filtrate from the lithium fluoride. The following results are given:—

Taken.			Found.	Calculated.
Li_2CO_3 .	Na_2CO_3 .	KNO_3 or KCl .	Li_2SO_4 .	Li_2SO_4 .
Grm.	Grm.	Grm.	Grm.	Grm.
0.109	0.300	0.300	0.148	0.1486
0.050	0.350	0.450	0.075	0.0743
0.030	0.120	0.060	0.045	0.0446
0.100	0.200	0.200	0.1475	0.1486

To apply the above method to the analysis of mineral waters containing lithium, the silica, iron, alkaline earths, and magnesium must first be removed and the lithium partially separated from the sodium and potassium by treating the mixed chlorides first with 90 per cent. alcohol and then with a mixture of 90 per cent. alcohol and ether. The resulting solution then contains the whole of the lithium together with a small proportion of the other alkalis and at times traces of magnesium as chlorides, and in this the lithium is separated as fluoride as above. If magnesium be present this will also be precipitated as fluoride. To determine its amount the resulting sulphates are dissolved and the magnesium precipitated as phosphate, the lithium being obtained by difference. As a check on the absence of sodium and potassium from the precipitate of fluoride, the weight of the sulphate should be about twice that of the fluoride (2.115 times exactly). Two mineral waters obtained from the neighbourhood of Beaune, in the department Côte-d'Or were found to contain 0.240 and 0.310 gm. of lithium per litre respectively.—C. A. K.

The Volumetric Determination of Carbon Dioxide in Carbonates. E. Jäger and G. Krüss. *Zeits. Anal. Chem.* **27**, 721—724.

A QUANTITY of the carbonate capable of yielding 40—50 cc. of gaseous carbon dioxide is decomposed in a 100 cc. flask by the addition of hydrochloric acid of 1.001 sp. gr. The stopper of the flask contains, besides a stop-cock funnel for the addition of the acid, a capillary tube bent twice at right angles, and connected with a Hempel burette. Before starting the decomposition, the flask is placed in a beaker

of water for two minutes to bring it to the temperature of the room; the acid is then gradually added, the pressure tube of the burette being meanwhile lowered so that the decomposition takes place under reduced pressure. As soon as the volume of gas in the measuring tube becomes constant, the decomposition is complete; the flask is then again placed in a beaker containing water for a few minutes, and the volume of gas read off. This volume, less the number of cc. of acid added, gives the volume of carbon dioxide found, which must be corrected for temperature and pressure. (1 cc. of CO_2 at 0 and 760 mm. = 0.0019663 gm.) An excess of acid should be avoided, so as to reduce the error due to absorption to a minimum. By surrounding the gas burette with a water jacket, the process may be rendered more accurate. Test analyses with sodium carbonate, and lecland spar are given in which the errors vary from 0.01 per cent. to 0.17 per cent. from the theoretical amount of carbon dioxide.—C. A. K.

Separation of Zinc and Cobalt. By H. Baubigny. *Compt. Rend.* **108**, 450—453.

CONSIDERING the completeness with which zinc can be separated from nickel by the action of hydrogen sulphide in a slightly acid solution (this Journal, 1889, 307), and also that cobalt salts are less easily converted into sulphide than those of nickel, the author has attempted the separation of zinc from cobalt by the same method. He finds, however, that in an acetic solution a little cobalt sulphide is always carried down with the zinc sulphide, giving the latter a green colour. With free sulphuric acid, in quantity about equivalent to the zinc and cobalt salts reckoned as sulphates, in a solution dilute enough to ensure entire precipitation of the zinc, better results are obtained. If the quantity of cobalt present be small, the separation is complete, and nearly so when very little zinc is present. With larger amounts of either metal the precipitated sulphides should be reconverted into sulphates, and the separation repeated.—J. M. H. M.

The Application of Pettenkofer's Reaction for Bile to the Detection of Free Acid in Aluminium Sulphate, Alum, &c. E. Egger. *Zeits. Anal. Chem.* **27**, 725—728.

THE author has reversed Pettenkofer's reaction, as modified by Mylius, for the detection of cholic acid by the blood-red colouration formed on the addition of furfuraldehyde and sulphuric acid, and finds that if a solution containing 0.00004 gm. of SO_3 be treated with two drops of a solution of furfuraldehyde (1 drop of aldehyde to 10 of water) and a little cholic acid, and the whole warmed in a porcelain dish on the water-bath, a distinct red colouration is formed. To test alum for free sulphuric acid the sample is first moistened with water and then treated with 25 cc. of a mixture of 2 parts of alcohol and 3 parts of ether in the cold for 24 hours, the resulting liquid filtered, and evaporated gently on the water-bath to about 1 cc., and then the cholic acid and furfuraldehyde added; 0.0032 gm. of free SO_3 in 20 grms. of alum, equal to 0.016 per cent., can be detected thus. The same limit of the reaction obtains with the presence of free acid in neutral potassium sulphate, magnesium sulphate and zinc sulphate; with aluminium sulphate, the limit is 0.030 per cent. of free sulphuric acid.

The author has also compared the delicacy of Jorissen's method (*Zeits. Anal. Chem.* **26**, 111) for the detection of free acid with the above. He finds that the addition of 0.0003 to 0.0004 gm. of free sulphuric acid (SO_3) to 3 cc. of acetic acid and 2 drops of Gurjun balsam are necessary in order to get a distinct blue colouration. With aluminium sulphate, zinc sulphate and alum, the pure substances, when added to the mixture of acetic acid and Gurjun balsam in the form of a coarsely-ground powder, give no colouration, but if they be ground very fine the characteristic blue colouration ensues in each case. Hydrochloric and phosphoric acids both give Pettenkofer's reaction with furfuraldehyde and cholic acid, but the test is far less delicate than with sulphuric acid; acetic and tartaric acid do not only give no reaction, but their presence decreases the delicacy of the test for sulphuric acid.—C. A. K.

Estimation of Total Organic Nitrogen in Water by the Kjeldahl Process. H. Leffmann and W. Beau. Amer. Chem. J. 11. (Reprint.)

THE following reagents must first of all be made up:—

Caustic soda solution: 100 grms. of caustic soda are dissolved in about a litre of water; this is boiled down to about half its bulk and then made up to a litre with water free from ammonia.

Sodium carbonate solution: 200 grms. of pure sodium carbonate are dissolved in a litre of water, and the solution boiled briskly until several hundred cc. have been evaporated.

In order to determine the ammoniacal nitrogen in a water, without distillation, 200 cc. are placed in a stoppered bottle, 2 cc. each of the solutions of sodium carbonate and caustic soda are added, the stopper inserted, the solutions mixed and allowed to stand for an hour or two. By this means the calcium and magnesium are removed, which would otherwise interfere with the colour reaction in Nesslerising. The clear liquid is then pipetted off, filtered through cotton-wool, and 100 cc. Nesslerised.

Total organic and ammoniacal nitrogen is estimated as follows: 500 cc. of the water are placed in a round-bottomed flask, 10 cc. of concentrated sulphuric acid added, and the mixture boiled down until the water is driven off and the acid is colourless or pale yellow. A little powdered potassium permanganate is then added until, on shaking, the liquid acquires a green colour, after which the flask is heated for a few minutes until the liquid becomes colourless. After cooling, 50 cc. of water are added, and then a slight excess of the caustic soda solution (about 150 cc. will be found necessary); 2 cc. of sodium carbonate solution are then added to ensure precipitation of the calcium and magnesium. The liquid is cooled by immersing the flask in cold water, then made up to 250 cc., transferred to a stoppered bottle and allowed to stand for about an hour, or until the greater portion of the precipitate has subsided. The clearer portion of the liquid is then pipetted off and filtered through cotton-wool. An aliquot portion of the filtrate is Nesslerised. For this the authors prefer to use 100 cc. made up to 200 cc. A blank experiment must be made to determine the amount of nitrogenous impurity in the reagents used. The method is stated to give exceedingly trustworthy results.—T. L. B.

Action of Ozone on Guaiacum Resin. N. Kowalewsky. Centralbl. f. d. med. Wissensch. 27, 65.

GUAIACUM resin gives not merely one blue oxidation product, but a whole series of coloured products. Paper soaked in tincture of guaiacum shows the colours well, the different colours appearing in succession. On the dry paper ozone has to all appearances no action, but, if paper, which has been exposed dry to ozone for a couple of minutes, be afterwards moistened, it takes the colouration. This property it retains for a quarter of an hour or more after exposure to the ozone. Water through which ozone has been passed has no action on the paper.

Exactly similar reactions are shown with iodine.—T. L. B.

On the Determination of Glycerol by Oxidation with Potassium Permanganate in Acid Solution. H. Grünwald. Zeits. f. angew. Chem. 1889, 34—35.

THE author has tested the method of Planchon (this Journal, 1888, 779), and has obtained satisfactory results by absorbing the evolved carbonic acid in caustic potash solution, instead of the soda-lime recommended by Planchon.—G. H. B.

On the Adulteration of Lard with Cotton-seed Oil. A. Binjard and G. Wallbauer. Zeits. f. angew. Chem. 1889, 119—121.

THE authors' work was undertaken in connexion with an official inquiry into the state of purity of American lard in the wholesale market. Out of 42 samples examined, 34 were adulterated with cotton-seed oil in proportions varying from 19 to 53 per cent. The colour tests used for the qualitative examination were the Bechli-Hehner silver nitrate test and Labiche's reaction (this Journal, 1888, 135 and 404). The amount of cotton-seed oil present was estimated by means of Hübl's iodine method.—G. H. B.

New Books.

THE USES OF PLANTS. A Manual of Economic Botany, with special reference to Vegetable Products introduced during the last fifty years. By G. S. BOULGER, F.L.S., F.G.S., Professor of Botany at the City of London College, &c. London: Roper & Drowley, 11, Ludgate Hill. 1889.

SMALL 8vo volume, bound in cloth and containing 192 pages of subject-matter, four additionally devoted to a systematic synoptical index and 14 to a general index. The practical character of the work appears in the contents, arranged as follows:—INTRODUCTION—i. Economic Botany more than fifty years ago. ii. The Progress of Economic Botany in England during the last fifty years (1837—1887). PART I.—FOODS, FOOD-STUFFS, AND FOOD-ADJUNCTS. Section 1. Starches and Bread-Stuffs. (2.) Sugars. (3.) Pulse. (4.) Roots and Tubers. (5.) "Vegetables." (6.) Fruits. (7.) Nuts. (8.) Food-Adjuncts: (a) Alcoholic. (b) Condiments. (c.) Flavours. (d.) Alkaloids. II.—MATERIA MEDICA. III.—OILS AND OIL SEEDS, &c. IV.—GUMS, RESINS, &c. Section 1. Gums. 2. Resins. 3. Caoutchoucs and Guttas. V.—DYES AND TANNING MATERIALS. VI.—FIBRES AND PAPER MATERIALS. VII.—TIMBER AND OTHER WOODS. VIII.—AGRICULTURAL PLANTS. IX.—MISCELLANEOUS PRODUCTS.

CHEMICAL LECTURE NOTES. By PETER T. AUSTEN, PH.D., F.C.S., Professor of General and Applied Chemistry, Rutgers College and the New Jersey State Scientific School, New York: John Wiley and Sons, 15, Astor Place. 1888.

THIS is a small book containing a collection of chemical notes and observations on certain topics which, as experience has shown the author, cause the student more or less trouble. The work is written in a conversational style, the effort being evidently not only to teach the elements of chemistry and chemical physics, but to train the reasoning faculties and powers of expression in language. The style is at times somewhat racy; for example, under the heading of the "Classification of the Sciences," the opening sentence runs thus:—"In all attempts at classification there will occur between the various classes tracts of No-man's Land of greater or less dimensions, and these not seldom give rise to squabbles between those who wish to rule them." "The reason of this is that Nature does not deal with classes." "Chemistry and Physics are distinguishable for a time, but soon a field is reached that belongs to both." The text of this little work covers 96 pages; there is a Table of Contents, but no alphabetical index; indeed the character of the book does not demand it. Under the heading, "The Chemical Factor in Human Progress," some interesting and simple accounts are given of certain applications of chemistry to the industrial, medical, and sanitary arts.

FABRICATION ET CONTROLE DES CHAUX HYDRAULIQUES ET DES CEMENTS. Théorie et Pratique. Influences réciproques et simultanées des différentes opérations et de la Composition sur la Solidification. Énergie. Thermodynamique. Thermochimie. Par H. BONNANIE, Conducteur des Ponts et Chaussées, &c., &c. Paris: Gauthier-Villars et Fils, Imprimeurs-Libraires du Bureau des Longitudes de l'École Polytechnique. Quai des Grands-Augustins, 55. 1888. London: H. Grevel & Co., 33, King Street, Covent Garden.

OCTAVO volume in paper cover, containing 276 pages of subject-matter with which 22 wood engravings and diagrams are interspersed. There is no alphabetical index, but the work commences with a full and carefully arranged Table of Contents. The author in his preface emphasises the importance and value he believes may be found in his work

for constructors of bridges and permanent ways, military engineers, and railroad companies. The matter in this book is subdivided as follows:—**CHAP. I.** Historical, with various theories and considerations. **II.** Manufacture of Hydraulic Limes and Cements. **III.** Roasting: The relationship between the roasting, the initial attraction, and the final resistance. **IV.** Preparation of mortars and cements, and the various theories in connexion therewith, Le Châtelier's theory. The general theory of Hydraulicity. **APPENDIX.** Modern Theories. Energy: Notions relating to the Mechanical Theory of Heat; Equilibrium between Heat and Chemical Affinity. Dissociation. Principles of Mechanical Chemistry.

HISTOIRE SCIENTIFIQUE ET INDUSTRIELLE DU NOIR D'ANILINE. Par E. NOELTING, Directeur de l'École de Chimie de Mulhouse. Mulhouse: H. Stuckelberger, Libraire-Éditeur. (C. Detloff's Buchhandlung.) 1889.

This work, large 8vo form, bound as a pamphlet, appears to be devoted in the first place to dealing with the scientific and historic development of Aniline-black, and thereafter to the critical examination in the light of historic development, of the claims of M. Grawitz to patent rights, which, if granted, would give him the monopoly of this industry in France. Amongst the various distinguished opinions on this subject appended is that of Prof. A. W. Hofmann. The work contains a short preface, 169 pages of subject-matter, and at the end a concise Table of Contents.

DAS FURFURAN UND SEINE DERIVATE. Von Dr. ADOLF BENDER. Berlin: S.W. R. Gaertner's Verlagshandlung, Hermann Heyfelder. Schönebergerstrasse, 26. London: H. Grevel and Co., 33, King Street, Covent Garden.

PAMPHLET. 8vo size, the tabulated contents of which are announced as having been taken from a prize essay on the "Derivatives of Indole, Pyrrol, Furfuran, and Thiophen." The problem to be solved in this essay appears to have been the most rational mode of classification and arrangement of the members of the group referred to, with their principal derivatives. The method followed is foreshadowed in the "Vorbemerkungen." Then follows a complete index of reference on the literature of the subject, followed by 11 pages of text dealing with the occurrence and chemical development of Furfuran and thereafter with that of its derivatives in directions A, B, and C. The tabulated list follows, covering 71 pages, and arranged according to the scheme aforesaid. The grouping embraces the following items, represented in the columns of the table:—Name; Origin; Appearance; Melting Point; Boiling Point; Odour; Solubility in Water, Alcohol, Ether, &c.; Reactions; Remarks.

Trade Report.

(From Board of Trade and other Journals.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Classification of Articles in Customs Tariff.

Note.—Pound = 36 lbs. avoirdupois. Rouble = 3s. 2d.

The following decisions have been given by the Russian Customs authorities:—

Extract of hops and lupuline (trituated hops) generally.—Section 48, point 2. Duty, 2 roubles gold per pound.

Hydrofluoric acid imported in gutta-percha vessels, together with the vessels containing the acid.—Section 140. Duty, 2 roubles 40 copecks gold per pound.

Purified glycerin.—Section 141, point 3. Duty, 65 copecks gold per pound.

FRANCE.

Modification of Customs Duty on Collodion.

By a recent decision of the French Customs authorities, the *ad valorem* duty of 5 per cent. formerly levied on collodion as a chemical product not distinguished, has been converted to the specific rate of 15 francs per 100 kilos.

BELGIUM.

Imposition of an Import Duty on Saccharine.

The *Moniteur Belge* for the 22nd May publishes the text of a law of the Belgian Government imposing an import duty on saccharine. The following is a translation of the law in question:—

Art. 1. The import duty on saccharine or benzoic sulphinaide is fixed at 140 francs per kilogramme. Soluble saccharine, in a solid or liquid state, and all products containing more than one-half per cent. of saccharine, are subject to the same duty.

Art. 2. Products prepared with the aid of saccharine, other than those indicated in the preceding article, are assimilated, for the application of import duties, to products prepared with the aid of sugar. The classification of them is determined according to the sweetening power of saccharine compared with that of sugar.

Art. 3. The Government is empowered to establish on the manufacture of saccharine an excise duty not exceeding the import duty, and to take the necessary steps to secure the collection of this tax and the inspection of the factories.

THE NETHERLANDS.

Classification of Articles in Customs Tariff.

The following decisions affecting the classification of articles in the Netherlands Customs Tariff have recently been given by the Netherlands Customs authorities:—

Turpentine varnish is included in the category of colours prepared in oil, and pays therefore 5 per cent. *ad valorem*, whether prepared with turpentine or oil of turpentine.

Tariff Classification of Sulphonal.

According to a recent decision of the Netherlands Customs authorities, sulphonal is subject to an import duty of 1 florin 30 cents per kilogramme.

Modification of Import Duties on Vinegar.

A law of the 4th May last has fixed the import duties on vinegars as follows:—

Vinegar, including pyroligneous acid and acetic acid, crystallised or liquid:—

Containing, per litre, less than 100 grammes of acetic acid, not mixed with water, 3 florins per hectolitre.

Containing, per litre, 100 grammes of acetic acid, not mixed with water, 3 florins 50 cents per hectolitre.

Containing a larger quantity of acetic acid, in proportion to the above duties.

SPAIN.

Prohibition of the Import of Saccharine as an Article of Food.

According to the *Deutsches Handels-Archiv* a decree, dated the 3rd April last, has been issued, providing that the imports of saccharine for purposes of food, as well as of all substances which contain saccharine in any quantity and serving for similar purposes, is prohibited.

ITALY.

Classification of Articles in Customs Tariff.

Note.—Lire = $9\frac{5}{16}$ d. Quintal = 220·4 lb. avoirdupois.

The following decisions have recently been given by the Italian Customs authorities:—

Chloride of Metilene (? Methyl) and effervescent carbonate of lithine (prob. lithia).—Category 62. Duty, 120 lire per quintal.

Creoline (an antiseptic).—Category 61. Duty, 10 lire per quintal.

Anticryptogamic powder (composed of sulphur, with the addition of sulphate of lime and sulphate of copper, substituted for sulphur in the treatment of diseases of the vine).—Category 248. Duty, 1·10 lire per quintal.

SWITZERLAND.

Classification of Drying Oils.

Drying oils are taken out of Category 39.

AUSTRIA-HUNGARY.

Classification of Articles in Customs Tariff.

The following decisions affecting the classification of articles in the Austro-Hungarian Customs Tariff have recently been given by the Austro-Hungarian Customs authorities:—

Chemical products, such as toluidine, sulphu-naphthylamic acid and its salts, polysulphuric acid and its salts, are classified under Category 322 of the tariff, and pay 1·50 florins per 100 kilogrammes.

GREECE.

Alterations in Customs Tariff.

Note.—Oke = 2·8 lb. avoirdupois. Lepta = $9\frac{2}{10}$ d.

A despatch, dated the 30th April last, has been received at the Foreign Office from Sir E. Monson, Her Majesty's Minister at Athens, enclosing translation of a law just gazetted, making certain modifications in the Customs Tariff of Greece. The following is an extract from the translation in question:—

The following alterations shall be made in the Customs Tariff:—

1. The words "chalk in general" shall be struck off from the text of alinea c of Class 61.

2. An alinea marked f shall be added to this class (61), which shall be as follows:—

"Chalk in general, 2 lepta per oke."

3. An alinea marked b shall be added to Class 94, which shall be as follows:—

"Starch from potatoes of a bitter taste, 5 lepta per oke."

4. The words "in general, namely" in alinea c of Class 103, shall be substituted by the word "refined."

5. An alinea d shall be added to the above-mentioned class to the following effect:—

"Unrefined acids (for market) 10 lepta per oke."

UNITED STATES.

Recent Customs Decisions.

The following decisions affecting the classification of articles in the Customs Tariff and the application of the Customs law of the United States, have recently been given by the United States Customs authorities:—

In assessing the dutiable weight of imported rape-seed oil, which is subject to duty at the rate of 10 cents per gallon under T. I. 28, the standard of $7\frac{1}{2}$ pounds to the gallon is to be taken.

An article found on examination to be the elementary substance known as potassium, the metallic base of potash, is dutiable under paragraph 215 (T. I.), new, as a metal unwrought, and not free by assimilation to sodium.

So-called "ammonia-alkali" found on examination to be soda ash, is dutiable as such under paragraph 71 of the indexed tariff at the rate of a quarter of a cent per pound.

On the exportation of an article known as the "solid ingredient of rackarock," made by the Rand Drill Company of New York, from imported chlorate of potash, and packed in sacks or earthenware, there shall be allowed a drawback of the duty paid on a quantity of the imported chlorate used in the manufacture equal to the net weight of the exported prepared chlorate, less the legal retention of 10 per cent.

Savin, sage, and santal-wood oils are classified under T. I. 92, at the rate of 25 per cent. *ad valorem*; so-called preparations of coal-tar which are really chemical compounds, whereof coal-tar is not a constituent, and which are not wholly derived from coal-tar, nor sold as coal-tar preparations similar in general characteristics to salol, are dutiable as above; lactucarium, which is the juice of the lactucarium plant, inspissated by mechanical means, and used exclusively as a medicine, is dutiable under T. I. 93.

An article found upon chemical analysis to be a chemical salt known as "alpha-naphthylamine-mono-sulphonated soda salt" is dutiable under paragraph 92, for chemical salts or compounds not specially enumerated or provided for, at the rate of 25 per cent. *ad valorem*.

ARGENTINE CUSTOMS LAW FOR 1889.

The following are extracted from the text of the Customs Law of the Argentine Republic for the year 1889:—

Art. 1. All goods of foreign origin, and imported for consumption, will pay a duty of 25 per cent. *ad valorem*.

The following articles are excepted and will pay as follows:—

- a. 50 per cent. on gunpowder, munitions, and perfumery.
- b. 45 per cent. on matches (except wax).
- c. 10 per cent. on all kinds of paper.
- d. 5 per cent. on rough common salt, sulphuric acid, and sulphate of lime.
- e. The following specific duties are hereby imposed:—

Note.—Peso = 4s. 2d.

	Ps.
Alcohol in casks, fine, at 30° strength. per litre	0·15
Petroleum..... " "	0·25
Stearine or glycerin candles..... per kilo.	0·15
Stearine candles..... " "	0·12
Wax matches..... " "	0·50

Art. 2. The following articles are admitted free:—Powder for blasting, raw sulphur, sheep dip, and drugs.

Art. 3. All Argentine products or manufactured articles are free of export duty.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

THE SALE OF COCOANUT BUTTER IN SAXONY.

Mr. G. Strachey, Her Majesty's Chargé d'Affaires at Dresden, in a despatch to the Foreign Office, dated the 11th May last, with reference to the sale of cocoanut butter in Saxony, says:—

"The local sanitary police decided some time since that the regulations of the margarine law were applicable to cocoanut butter. On the complaint of some Mannheim makers of the article, the provincial authorities quashed this decision as illegal.

"They ruled that the cocoanut butter, proving on analysis to be in the nature of a pure vegetable fat, was not a preparation similar to animal butter in the sense of the margarine law. This substance might, therefore, lawfully bear the designation of cocoanut butter, and could be sold without restriction."

PETROLEUM WELLS IN VENEZUELA.

See Board of Trade Journal for June, p. 662.

OUR TRADE WITH SERBIA.

Our commercial treaty with Serbia has entered upon its last year of life, and as to our future trade with that country much will depend upon the terms which the Serbian Government will be prepared to accord us under new agreements. Austria-Hungary has hitherto held Serbia in her grip, but it is not likely that she will be induced to make the monopoly of her powerful neighbour absolute. Foreign capital may meanwhile, our Consul at Nisch says, find profitable employment in aiding to develop the rich natural resources of the country, such as vines and minerals, upon the future of which the purchasing power of Serbia will most largely depend. There is no scope yet for the employment of large capitals in any purely commercial undertakings.

It is suggested that with a view to the encouragement of British trade with the Balkan States a general British import agency should be established. This agency would have for its first object the convincing Servians of the superior durability, practical utility, and real cheapness of British goods; and although it would have many difficulties to encounter, it would, it is believed, ultimately get the better of German manufactures, which are turned out at the same price as ours, but which pay a higher transport freight to Serbia than the British articles coming by sea. The cheapness of the sea route would especially benefit British trade in big orders.—*Pall Mall Gazette*.

MISCELLANEOUS TRADE NOTICES.

EXPORT OF ALCOHOL FROM RUSSIA.

The Russian *Grajdanine*, basing its remarks on the latest publications of the Russian excise department, points out that the export of Russian alcohol is increasing year by year. The maximum attained in 1887 was three times the average of the export of the last 10 years (2,616,222 vedros per annum); the average of the export of the last five years is 56 per cent. lower than that of 1887, which itself is 5.2 per cent. higher than that of 1886. The quantity exported is equivalent to 19.8 per cent. of the entire alcohol manufactured in Russia in the course of the year. Two-thirds of the total quantity exported (6½ million vedros) were supplied by Poland and the Baltic Provinces.

ZINC PRODUCTION IN SILESIA.

The Belgian *Bulletin du Musée Commercial* publishes some interesting statistics with regard to the production of zinc in Europe and in the United States during the years 1880 to 1888. These figures draw attention to the important place occupied in this industry by the province of Silesia. The production of zinc in 1880 was 208,690 tons in Europe and 23,239 tons in the United States. In 1888 the figures were 267,005 tons in Europe and 50,000 tons in the United States. Of the divisions of the world, Silesia took the second place in zinc production, with 83,375 tons in 1888, as against 64,459 tons during 1880. Belgium, in 1888, produced 133,245 tons (but part of the Rhine Province was included in this amount); the United States, 50,000 tons; and then followed Great Britain with 26,633 tons; France and Spain, with 16,140 tons; Austria, with 3,827 tons; and finally Poland, with 3,785 tons.

METAL PRODUCTION IN AUSTRIA-HUNGARY.

According to *Genie Civil*, since the moment when Hungary secured the economical and industrial autonomy from Austria, the progress of her iron manufactures has been steadily marked. The total production, which in 1886, before the dual control had been effected, was only 106,720 tons, reached the figure of 234,667 tons in 1888, and, therefore, has more than doubled. It is the chain of the Carpathian Mountains, forming a vast girdle around the great plain of the Danube, which furnishes Hungary with

iron ore, abundant in quantity and of an excellent quality; and it is in the region north of those mountains (in the districts of Gömör, Zips, Abauj, Torna, and Ziptan) that very rapid progress has recently been made.

Although the forests are still abundant, the large blast furnaces burning Silesian coal begin more and more to take the place of the little charcoal blast furnaces. Mr. Wedding, of Berlin, who is well known for his numerous treatises on the properties of iron and steel, draws attention to this new condition of things in a recent article in *Stahl und Eisen*, as one to which the notice of metallurgists ought to be particularly drawn. This paper gives particulars, of an unusual fulness and accuracy, on the comparative *roulement* of the old and new wood and coke furnaces, comparing, in particular, the manufacture of Bessemer steel at the Diosgyör factory, which belongs to the Hungarian State, with that of Martin steel at the same factory, and in those at Brezowa and at Saljo Tarjan. It appears that in Hungary the superiority of the Martin steel over the Bessemer steel is universally recognised.

A JAPANESE CEMENT.

There is a probability, says the *Japan Gazette*, that the day of foreign cement in Japan is past. A Yokohama cement manufacturer and dealer has discovered a stone called *mekura* in Noto district which possesses remarkable qualities as a cement material. If the stated results of his tests be correct they are very good. It is said that the cement will bear a weight of 400 lb. to 500 lb. per square *sun* (about 1½ inch). Foreign cement is sold at about 4.70 dols. per barrel, while the estimated sale price of the cement under notice is about 2.50 dols.

AGRICULTURE IN CANADA.

The following remarks are taken from the report of the Select Standing Committee on Agriculture and Colonisation, presented to the Dominion House of Commons on the 27th April last:—

Professor Saunders, director of Government experimental farms, was examined by the Committee, and he stated that the results of numerous experiments had shown that the wheat called "Ladoga" ripens fully 10 days earlier than the "Red Fyfe." There appears, however, to have been considerable difference in the opinion expressed by the different bodies of experts to which the wheat was submitted, as to its quality, the same samples having been graded variously as "hard wheat," "soft wheat," and "No. 1 hard."

Mr. Saunders having stated that a series of careful experiments had been made by the chemist of the central experimental farm, which demonstrated that the Ladoga was superior in gluten to the Red Fyfe, while reports from bakers, and specimens of bread shown, proved that the flour produced from it was strong in bread-making qualities, even more so than that from Red Fyfe, the colour of the bread, however, being a shade less white.

The remarks made by Mr. Saunders on the subject of the barley product of the Dominion and the importance for Canadian farmers of growing varieties suitable for malting purposes in England, cannot be too carefully considered by them. He showed that we were in danger, from two causes, of a lessened demand for Canadian four and six rowed varieties in the United States markets, which had hitherto taken such large quantities; and, on the other hand, that the importation into England, for malting purposes, reached the quantity of 35,000,000 bushels a year, and for which much higher prices are paid than our farmers have hitherto obtained. It has, therefore, become a matter of prime importance for Canadian farmers to produce varieties to suit the English market. The kind used in England is the two-rowed, the four and six rowed being not at all saleable there for malting purposes. Mr. Saunders stated that a large number of samples of the very best varieties of the two-rowed had been distributed among farmers in different parts of the Dominion.

Mr. Saunders stated that 913 seed-germinating tests had been made during the year, of which 216 were of frozen wheat, 20 of frozen oats, and 19 of frozen barley.

These tests showed that the vitality of frozen wheat varied from 21 to 99 per cent.; frozen barley, 14 to 99 per cent.; and frozen oats from 2 to 94 per cent. The conclusion arrived at was that it was most unwise for farmers to sow anything but good seed, unless driven to it by absolute necessity, the rule being the same in vegetable as in animal life, from which it followed that a good constitution of seed was necessary in plant life to produce a good result.

OLIVE OIL.

Spanish olive oil having had a very low reputation, some producers have of late been trying hard to improve its quality, and fit it for table use. Some of the Seville growers are now making an excellent oil which commands a ready sale at more than double the price heretofore obtained. As the cost of making good oil is by no means double that of making bad, there is likelihood of other makers following this profitable example.—*Industries*.

A NEW LUBRICANT.

A Berlin correspondent says that mustard-seed oil has long been used in Germany as a condiment, and is principally manufactured at Ilversgehofen, near Erfurt. Now, however, there has been a new use found for this substance. As it only begins to solidify at a temperature of 9° to 10° C., and, moreover, forms no fatty acid which could affect metals, it has recently been employed as a lubricant for machinery. According to experiments made by Professor G. Hermann, Aix-la-Chapelle, its lubricating power is as 263 to 168 as compared with olive oil, while it is more than double that of naphtha. In order to prevent the workmen from using the mustard-seed oil for any but lubricating purposes it is denaturalised through the agency of a small quantity of petroleum.—*Ironmonger*.

ALCOHOL AND WATER TANNINS.

M. Adrian was recently consulted by the Custom House officials in regard to the possibility of distinguishing water tannins from alcohol tannins, the second alone being liable to duty. On making experiments to elucidate the question, he has found that when tannins prepared with water are exhausted with ether, the liquors evaporated and the residue redissolved in alcohol, the spirituous solution will, on being mixed with water, afford no precipitate. Alcohol tannins, on the contrary, even when made with weak spirit, contain resinous and fatty matters which, under the conditions described, will give an appreciable precipitate.—*Chemist and Druggist*.

THE ZINC INDUSTRY ON THE INCREASE.

The active demand which has sprung up for zinc during the last few years has led to a greatly increased production of that metal, which is now largely used for galvanising iron and many other purposes. The quantity of zinc produced in Europe and the United States increased year by year from 1880 to 1888, except during the period between 1885 and 1886, when there was a slight diminution, especially as regards Great Britain. The production, which in 1880 amounted to 208,005 tons in Europe and to 23,239 tons in the United States, had risen in 1888 to 267,005 and 50,000 tons respectively. The largest quantity is produced in Belgium and the Rhineland; these districts jointly represent about 134,000 tons, and after these come Silesia, with about 84,000 tons. Next in order comes the United States, contributing 50,000 tons, as already indicated, followed by Great Britain with about 27,000 tons. The zinc works of France and Spain show a turn-out of some 16,000 tons, while the Austrian and Polish yield barely exceeds 7,600 tons.—*Ironmonger*.

A GREAT IRON-ORE DEPOSIT.

A Canadian contemporary states:—"The iron-ore deposit at St. George's Bay, Newfoundland, has excited the wonder of the experts who have visited it. Doctor Stevens, mining expert from New York, has inspected the property and found the visible width of the deposit to be 171 feet, the distance beyond not being ascertainable as the deposit is

hidden by moss and shrubbery. The length of the deposit has not been determined, but it may be described as a mountain of magnetic ore of the purest quality, free from sulphur and phosphorus, and just suitable for the manufacture of steel. Analyses by Professor Pike give an average percentage of 90.3 per cent. of magnetic iron. The samples were taken from the surface, and the solid vein will undoubtedly give still higher results. A deep gulch cuts through this mountain of ore, exposing the lode, which can be worked on either side—in fact, quarried out—at a cost of not over 20 c. a ton. From the bottom of the gulch to the top of the mountain, 750 feet, thousands of tons of ore, estimated at from 300,000 to 400,000 tons, are exposed, which can be mined without the aid of explosives. This magnificent deposit of ore is close to a fine harbour, with which it may be connected by a short tramway. Coal has been discovered close by, which adds immensely to the value of the property, and we are safe in predicting that in a few years St. George's Bay will be the seat of extensive steel and iron works. The property has been bonded to an American syndicate."—*Ironmonger*.

THE UTILISATION OF WASTE PICKLE.

The Corporation of West Bromwich have been discussing the question of the disposal of the spent "pickle" from the galvanising works of Messrs. Ash and Lacy. An application had been made by the firm to run the pickle into the sewers, but the sewerage committee had come to the conclusion that the pickle, in its raw state, was very injurious both to brick and iron sewers. The committee were also satisfied that the treatment of the pickle with limestone only partially neutralised the acid, but did not precipitate or remove iron from the liquid. The only method the committee had seen in use was the mixing of a quantity of milk of lime with the pickle, which was said to neutralise the acid and precipitate the iron. The committee could not recommend that Messrs. Ash and Lacy should connect with the sewers at present, but proposed that they should furnish a sample of the effluent they proposed to discharge to an eminent chemist, who should advise as to the results of a process to which it was to be subjected as regarded acid, iron, and any other ingredients which might prove prejudicial or injurious to the sewers. The council agreed with the conclusions of the committee. Proceedings are to be taken against a Wolverhampton firm of galvanisers for turning sulphuric acid into the borough sewers.—*Chemist and Druggist*.

THE MANUFACTURE OF PICRIC ACID AT REDDESH.

The magistrates have decided to grant the application of Messrs. Charles Lowe and Co. to be permitted to manufacture picric acid at their works on condition that a lock-up shed should be erected expressly for the purpose of storing the red lead, the key to be kept by some responsible person. Mr. Yates, on behalf of Mr. Lowe, assented to the condition imposed.—*Chemist and Druggist*.

THE RUSSIAN PETROLEUM TRADE.

A St. Petersburg correspondent says that the Russian petroleum trade is assuming vaster proportions every year, and the total exportation of naphtha from the Black Sea and overland amounted last year to nearly 35,000,000 pounds, as against 19,000,000 in 1887, and 15,000,000 in 1886. Russian petroleum now finds favour in many markets which were formerly exclusively supplied with American products, and, it is stated, the sales of the Russo-German Naphtha Company rose last year to 541,500 centners, as against 323,000 centners in 1887. During the first quarter of the present year Italy imported 35,715 double centners of Russian oil, or fully 18,000 double centners more than during the corresponding period of 1888.—*Ironmonger*.

INDIGO-GROWING IN THE UNITED STATES.

Efforts are being made, says the *O. P. & D. Reporter*, to again interest South Carolina planters and capitalists in the cultivation and manufacture of indigo, which was an important article of commerce in the Southern States before

Great Britain's relations with the American colonies were severed. The industry then thrived because the Southern manufacturers were given a bounty of 6d. on every lb. put upon the market; but the subsequent civil strifes seem to have discouraged the continuation of extensive indigo operations, and since then the cultivation has been confined principally to Florida, where the plant grows luxuriantly, and where the dyeing material is still prepared on a small scale for local use. Correspondence has passed between parties in Georgia and St. Paul relative to the advisability of reviving the industry in the South, and some figures have been presented which give a glowing account of prospective profits. The practical details to govern the new scheme come from an ex-manager of two indigo factories in the East Indies, who is now in the States, and desires to co-operate in such an undertaking.

AUSTRIAN PETROLEUM WELLS.

The success of the petroleum borings in Galicia are indicative soon that the Austro-Hungarian Empire will be totally independent of a foreign supply of oil. Formerly there was a tendency to speak slightly of Galician oil deposits owing to the fact that a large proportion of the wells were dug by hand. Of late years the American method of drilling has been introduced, and many Galicians have become accomplished drillers. In the Lodyna district wells of a profitable character have been bored. Galician wells have not the copiousness of Russian, but a readier market exists for the oil, and the demand for Lodyna petroleum is such that it is sold at a high rate long in advance of appearing on the surface. The oil belt of Lodyna is five miles long and intersected by a railway, thereby enabling the oil to be sent to the refineries at a trifling expense. A few years ago all the refineries in Galicia did not produce 1,000,000 gallons of refined oil, but now their production exceeds 6,000,000 gallons. The Austrian Government takes great interest in the development of the petroleum industry, and has adopted a protective policy which has already succeeded in establishing the Galician oil trade on a firm basis. In consequence of this and of such successes as the recent borings at Lodyna, where wells have been struck giving a profit of 500 or 600 per cent., the financial and commercial world in Austria has been deeply moved, and petroleum has caused much excitement.—*Engineering and Mining Journal*.

THE ROTHAMSTEAD TRUST.

Sir J. B. Lawes, Bart., having endowed the Rothamstead Agricultural Experimental Station with the sum of 100,000*l.*, for the purpose of carrying on the investigations after his death, has now appointed the trustees, who met at Rothamstead and elected the following officers:—Dr. John Evans (treasurer to the Royal Society), chairman; Sir John Thorold, deputy chairman; Dr. Hugo Müller, treasurer; and Mr. Herbert Cox, secretary. The trustees were conducted over the experiments by Sir J. B. Lawes and Mr. C. B. Lawes, and afterwards discussed the steps to be taken for working the trust.—*Standard*.

PLATING WITH COBALT.

Among the exhibits at the Royal Society's soirée on Wednesday, June 19th, were fine samples of plating with metallic cobalt, done at the Technical College at Finsbury. The cobalt has a better colour than nickel, can be applied to any of the common metals and to steel, and does not flake from to which it has been applied.—*Standard*.

REGULATIONS FOR WITHDRAWAL OF ALCOHOL FROM BOND FOR SCIENTIFIC PURPOSES OR FOR THE USE OF THE UNITED STATES.

Internal Revenue Manual, 1888, 280.

Section 3297 of the Revised Statutes, as amended by Act of May 3, 1878, provides that the Secretary of the Treasury is authorised to grant permits to scientific institutions or colleges of learning to withdraw alcohol in specified quantities from bond without payment of the internal revenue tax on the same (average, 1.70 dols. per United States gallon of 231 cub. in., of 95 per cent. strength absolute alcohol), or on the spirits from which the alcohol has been distilled, for the sole purpose of preserving specimens of anatomy, physiology, or natural history belonging to such institution, or for use in its chemical laboratory.

Alcohol may be withdrawn from bond under the above provisions of law, on application of the president or curator of the institution in which the same is to be used, to the Secretary of the Treasury, transmitted through the collector of internal revenue of the district in which the alcohol is located.

For full instructions in regard to this subject, and also as to the withdrawal of distilled spirits from warehouse free of tax for the use of the United States, see [Treasury] Department Circular, No. 2, dated January 2, 1886, and Treasury Department Circular dated March 26, 1889.

DUTY FREE SPIRITS FOR SCIENTIFIC USE.

The kinds and quantities of spirits withdrawn for scientific purposes and for the use of the United States, free of tax, extracted from the report of Commissioner of Internal Revenue 1888, are given in the following table:—

CLASS OF SPIRIT WITHDRAWN.

	Year ended 30th June.	
	1887.	1888.
	U. S. Gallons.	U. S. Gallons.
Whisky, Bourbon.....	492	631
„ Rye	729	854
Alcohol	18,673	21,271
Cologne spirits.....	1,373	2,858
Total quantity	21,165	25,614

The different colleges and schools, especially those of medicine, are availing themselves more and more of the provisions of the law and regulations, while on the other hand, the manufacturing druggists are using less grain alcohol for their extractions every year. The employment of a refined wood alcohol is increasing among the latter, where the extraction of the drug by alcohol is only a step in the manufacture.

THE IMPORTS AND EXPORTS OF DRUGS AND CHEMICALS.

STATISTICS.

MINERAL PRODUCTION OF CANADA IN 1888.

Through the courtesy of Mr. E. Coste, in charge of Mineral Statistics Division of the Geological Survey of Canada, we are enabled to give herewith a statement of the mineral production of Canada in 1888.

These figures show nominally a considerable increase in the value of Canadian mineral products from 12,959,073 *dols.* in 1887 to 16,500,000 *dols.* in 1888; but in reality 1,847,102 *dols.* of this increase is in a miscellaneous item not included in last year's returns.

The chief items show but little improvement. Of asbestos, the production declined 169 tons; that of building stone increased nearly 164,000 cubic yards. The production of cement has declined 19,000 barrels, and is very small, which is rather surprising, for Canada contains some very good cement rock.

The coal production has increased from 2,368,041 net tons in 1887 to 2,658,134 tons in 1888. And the output of coke, which is still very small, increased from 32,000 to 45,000 tons. These features are encouraging, though, considering the magnificent coal deposits of Nova Scotia, are but a very small part of what they should be.

Copper naturally felt the boom in the market, and increased from 3,260,424 pounds in 1887 to 5,562,864 pounds in 1888.

The production of gold has declined more than 3,000 ounces, and silver has scarcely increased.

The production of lead in ore has increased from about 100 tons to 337 tons; a ridiculously small amount, but one which will probably be increased hereafter by silver lead mines in British Columbia.

The production of sulphuric acid has increased $1\frac{3}{4}$ million pounds.

On the whole, this summary shows that Canada still lags far behind in the industrial race, notwithstanding its rich natural resources, which are very little known outside of or even in Canada, and comparatively very little enterprise is shown in Canada in their development.

Mexico, on our southern border, is developing its natural resources with much greater energy than Canada, and is attracting the capital that naturally would go north were attention directed to the natural resources of the country, and were inducements offered for its investment there.

THE MINERAL PRODUCTION OF CANADA IN 1888.

Name of Product.	Quantity. ¹	Value. ²

* Some returns yet to be received.

¹ Quantity marketed, except when otherwise specified. The tons are of 2,000 pounds.

² Market value, less charges of transport from point of production.

³ There was no production from Ontario this year, but there was an increase of 185 tons from the mines of the Eastern townships.

⁴ Oven coke; all the production of Nova Scotia.

⁵ Copper contents of Capelton ores at 12 cents per pound at the mine.

⁶ Nova Scotia gold is calculated at 19.50 dols. per ounce, and that from British Columbia at 17 dols.

* Some returns yet to be received.

⁷ Production of New Brunswick and Ontario, plus Nova Scotia exports.

⁸ This includes four rolling mills, one forge and the Londonderry Iron Works. Returns have not yet been received from six similar works, thus rendering the statement very incomplete. The total manufactures of iron will, however, be much larger than those of last year.

⁹ New Brunswick production plus Nova Scotia exports.

¹⁰ These figures are calculated from the inspection returns at 100 gallons crude for 38 gallons refined oil, and are computed at 1.903 dols. per barrel of 35 imperial gallons. The barrel of refined oil inspected was assumed to be 42 imperial gallons.

¹¹ Direct returns. The production is divided as follows:—

Ottawa County mines, 20,396 tons; Ontario mines, 2,089 tons; total, 22,485.

The exports as per Customs Department returns were 18,776 tons, valued at 208,609 dols.

¹² Exports plus silver contained in Capelton ores.

—*Engineering and Mining Journal.*

INCREASED CONSUMPTION OF COPPER.

The lower price of copper has told both upon the supplies and deliveries to the trade in England and France during May. While the supplies have fallen, the deliveries have very materially increased, and the stocks are less by over

7,000 tons. Messrs. H. R. Merton and Co.'s statistics give the following figures for the current year:—

Month.	Stock.	Price of G.M.B.	Supplies.	Deliveries.

—*Pall Mall Gazette.*

COST OF COAL PRODUCTION IN GERMANY AND FRANCE.

The following translation from *L'Echo des Mines et Metallurgie* gives the results of an investigation by M. Amedée Marteau, published in the Belgian *Moniteur des Interests Materiels*, of the comparative cost of the production of coal in France and Germany:—

The conclusion from this comparison is that Germany profits by a double advantage in the production of coal—first, from less costly manual labour, and secondly, from the nature of the beds, which permit the workmen to produce annually much more than the French workman, this second point having an influence over the former.

The extraction of coal in Germany, which only amounted to 33,396,400 tons in 1872, exceeded 58,000,000 tons in 1886, for a value of 300,720,000 marks. The price per ton amounts, therefore, to 5·18 marks, while it was 5·25 in 1880 and 8·88 in 1872. For lignite, the same progress is seen. From 9,018,000 tons for 24,496,000 marks in 1872, the extraction rose in 1886 to 15,617,000 tons for 40,270,000 marks. The price per ton fell consequently from 3·27 to 2·58 marks. The total extraction of fuel in Germany in 1886 amounted to about 73,500,000 tons, with a value of 340,977,000 marks. In Germany prices were 6·50 francs for coal and 3·25 francs for lignite, against 12·83 francs for coal in France, or 100 per cent. above the German price. Take, first, the difference of annual production per man. In 1860 it amounted in Germany to 160 tons, in 1870 to 229 tons, and in 1886 to 290 tons, or 130 tons more than in 1860. Therefore, about 250,000 men were employed to produce the 73,637,000 tons of coal and lignite in Germany in 1886. This makes, in round numbers, 294½ tons per man per year. It will be remarked that this high average is only obtained thanks to lignite, the average extraction of which is 555 tons, while for coal it was only 274 tons; but as in France no distinction is made in the kinds of fuel, it is preferable to calculate on the total production rather than on each particular branch. The average figure of production per man and per annum for coal in Germany is 274 tons; but this figure in the mines of Westphalia, which are by far the most considerable, since they engage more than 100,000 men, is 287 tons—almost the general average for the whole.

In France it needed 109,426 men in 1884 to produce 20,024,000 tons of coal, or about 190 tons per man per year.

With reference to wages, the following are the particulars for Germany in 1886:—

	Proportion of Numbers for each kind.	Annual Wages.	Average Daily Wages.
	Per Cent.	Francs.	Francs.
Colliers.....	54	1'148	3'80
Repairs, &c.	24	'828	2'77
Day labourers.....	19	'902	2'90
Children.....	3	'460	1'32
Total and average.	100	1,097'5	3'32

In France the maximum wages is 4·12 francs, and the average wages 3·83 francs, the annual average being 1,007·5 francs in Germany and 1,073 francs in France. It will be seen that the difference is 65·50 francs per annum and 0·51 franc per day. Taking account of these two elements to appreciate the difference in the cost of manual labour per ton of fuel, it will be seen that in Germany a miner produces 290 tons per annum for 1,007·5 francs, and a French miner 190 tons for 1,073 francs. It follows that the cost of manual labour per ton of coal extracted is 3·65 francs in France, against 3·50 francs in Germany, or an advantage of 2·15 francs per ton in favour of the latter country.

The principal coal basins of Germany, those of the Ruhr and Silesia, are of remarkable regularity. The working of a series of beds of average thickness is generally possible without gobbing, and almost without timbering. There are actually reckoned 74 workable beds, only considering those as such which have a thickness of more than 50 centimetres (19·68 ins.), forming a total thickness of 70 metres (230 ft.) of coal.—*Engineering and Mining Journal.*

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

7987. C. Le Fevre, jun. Carrying off superfluous vapours from furnaces and coppers. May 14.

8169. Solvay and Co. Multiple-acting distilling apparatus for caustifying liquors and separating the gases therefrom. Date applied for under Patents Act, 1883, sec. 103, 19 October 1888, being date of application in Belgium.

8173. A. Fryer. Improvements in the treatment of solutions or liquids for the purpose of concentration or evaporation, and in apparatus therefor. May 16.

8184. J. J. Hicks. Improvements in brewers' and other thermometers. May 16.

8252. J. J. Bodmer and G. R. Bodmer. Apparatus for the manufacture of compressed blocks. May 17.

8342. G. Olberg. Rotating furnaces. May 20.
 8596. J. G. Chapman. See Class XVI.
 8687. E. F. Varaldi. Vacuum pumps. May 24.
 8738. J. H. Parkinson. Improvements in and apparatus for isolating or separating gases of different liquefying points, which are mechanically mixed. May 27.
 8872. W. L. Wise.—From Solvay and Co., Belgium. Apparatus for the methodical and continuous treatment of pulverulent matters by fluids. May 28.
 8882. W. P. Branson and H. W. Neild. See Class XVIII.—A.
 8898. W. B. Wright. See Class II.
 8928. F. N. Mackay.—From J. Baxter and J. Muter. Improvements in filtering and in filter presses. May 28.
 9041. D. B. Morison. Apparatus for heating or evaporating liquids. May 31.
 9111. W. Buckwell. "Kilns and other furnaces by the conducting and utilisation of the carbonic acid gas and like products of combustion, and the apparatus therefor." June 1.
 9118. S. Berghelm. Improvements in crucibles for smelting ores, metals, glass, and other substances. June 1.
 9200. A. Keddle. Improvements relating to thermometers. Complete Specification. June 3.
 9204. J. E. Warren. Means or apparatus for use in filtering. Complete Specification. June 4.
 9321. F. M. Maynard. See Class XVII.
 9354. F. J. Brougham.—From S. Jönsson. Centrifugal separating machines. June 4.
 9375. G. King. Fastenings for retort lids. June 4.
 9759. F. Rybicka and R. Langer. Centrifugal saturating or soaking machines. June 13.
 9850. J. Brown and G. Johnston. Vacuum drying apparatus. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

4698. W. Bergh. Centrifugal fluid-separating machines. May 22.
 8561. The Gas Patents Syndicate.—From J. B. Archer. Kilns for firing bricks, &c. June 12.
 9916. G. A. Godillot. Furnaces for burning granular or pulverulent fuel, vegetable matter, and combustible liquids. May 22.
 11,357. M. Negro. Filter for any process of filtering. June 12.
 11,485. W. R. Watson and R. A. Robertson. Apparatus for evaporating, concentrating, and distilling liquids. May 29.
 12,357. R. A. Robertson. Centrifugal apparatus applicable for filtration. June 12.
 13,005. W. H. Grindley and W. S. Hensley. Pyrometers. June 5.
 14,599. S. Binks.—From J. Binks. Apparatus to prevent incrustation in boilers. June 19.
 16,793. J. Laidlaw. Oscillating centrifugal machines. June 12.
 16,791. J. Laidlaw. Centrifugal machines. June 12.

1889.

5559. H. Bergner. Centrifugal separating machines. May 29.
 6938. J. C. Felner and C. Ziegler. Travelling platforms, beds, or trucks for kilns or ovens for drying, burning, baking, &c. June 5.
 7149. C. Salomon. Drying, desiccating, and roasting apparatus. June 12.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

7996. G. Moir. Improved method and apparatus for the more economical use of fuel and the consumption of smoke, more applicable to boiler and other furnaces. May 14.
 8010. A. Myall.—From J. H. Lancaster, United States. Improvements in artificial fuel. May 14.
 8179. A. Runge. A new or improved charging trough for gas retorts, and apparatus for raising and operating the same. Complete Specification. May 16.
 8192. J. von Langer and L. Cooper. Process for generating gases known as water-gas and producer-gas. Complete Specification. May 16.
 8263. S. B. Darwin. Improvements in compounds to be used for manufacturing illuminating gas, the prevention of stoppages in ascension pipes, and the deposition of naphthalene. May 17.
 8281. J. E. Bedford. The purification of water-gas. May 18.
 8292. W. P. Thompson.—From W. Pope Hazard, United States. Improvements in apparatus for supplying hydrogen gas to furnaces. May 18.
 8519. V. B. D. Cooper. Improvements in the manufacture of gas for heating and other purposes. Complete Specification. May 22.
 8714. J. A. Norberg. Consuming smoke from furnaces. May 27.
 8724. W. R. Hutton. Improvements in the making of char or coke from coal, and obtaining tar and ammonia water and mixed gases therefrom. May 27.
 8832. H. Williams. Improvements in apparatus employed in the manufacture of water-gas for heating and lighting purposes. May 28.
 8892. G. Hatton and R. Lythgoe. Improvements in gas producers and other furnaces. May 29.
 8898. W. B. Wright. Improvements in means for feeding fluid fuel to furnaces, particularly applicable to the furnaces of brick kilns. Complete Specification. May 29.
 8993. S. W. Wilkinson. A process first for producing a clean gaseous fuel to be used in the evaporation of brine, and secondly for recovering the ammonia formed during the production of said gaseous fuel. May 30.
 9026. J. G. Irwin and A. Isaacs. A new and improved means of and apparatus for inducing incandescence for illuminating and other purposes. May 31.
 9061. B. van Steenberg. Improvements relating to the manufacture of water-gas, and to apparatus therefor. Complete Specification. May 31.
 9173. R. Simon and F. Wertenbruch. A new or improved method for the production of water-gas, and apparatus therefor. June 3.
 9279. B. Loomis. An improved process of and apparatus for manufacturing heating and illuminating gas. June 4.
 9288. W. Clark. Improvements in and relating to machines or apparatus for manufacturing gas. Complete Specification. June 4.
 9327. S. Fox and E. Blass. Improvements in the manufacture of water-gas and in apparatus therefor. June 4.
 9402. C. Deakin. Improvements in the production of lighting and heating gases. June 6.
 9454. G. Love. Improved apparatus for generating and consuming combustible gas. June 7.
 9535. G. Hatton and F. W. Harbord. Improvements in the manufacture of water-gas, and apparatus employed therein. June 8.
 9553. J. Armour and H. Armour. Improvements in and connected with stills for refining mineral oils. June 8.
 9619. G. Hatton and F. W. Harbord. Improvements in the manufacture of water-gas, and in apparatus for its production and use. June 11.

9621. H. Aitken. Improvements in making gas from coal or other bituminous or combustible substances. June 11.

9625. C. E. Miles. Improvements in the production of illuminating gas. June 11.

9626. C. E. Miles. Improved means and apparatus for the manufacture of producer or generator gas. June 11.

9783. A. Nickson and W. Black. Improvements in distilling shale, coal, or other oil and tar-yielding minerals, and in retorts therefor. June 14.

9868. A. Middleton, C. E. Fraser, and H. M. Carter. Improvements in artificial fuel. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8560. The Gas Patents Syndicate, Limited. — From J. B. Archer. Fuel gas burners. June 19.

9893. J. Jones. Vertical or inclined retorts for distilling shale, coal, &c. June 12.

10,186. A. Campbell and W. Boyd. Purifying coal-gas and other gaseous or liquid products of destructive distillation, partly applicable in the alkali manufacture. June 5.

11,294. L. Mond and G. Eschellmann. Obtaining inert gases. June 19.

11,443. J. Elliott. Gas-producing apparatus in which the carbonisation is continuous. June 12.

13,913. H. C. Webb. An inconsumable lamp wick. June 5.

14,878. J. King. Apparatus for taking off the gas from gas retorts and delivering it to hydraulic mains, and preventing the tar or liquors which condense in the ascension pipes from returning to the retorts. May 22.

1889.

2664. J. O. Spong. Means and apparatus for enriching and purifying the flame of coal-gas. May 29.

4807. W. J. Taylor. Firing furnaces and converting solid fuel into gaseous fuel, and apparatus therefor. May 29.

4969. P. Tarrington and D. S. McDonald. Portable apparatus for manufacturing gas. May 22.

6920. C. Kreissig and O. Seim. Producing an increased light effect of gas, paraffin, and other flames. May 29.

7152. H. J. Allison. — From A. G. N. Vermilya. Process and apparatus for generating heat. June 19.

7653. C. Dubois. Obtaining useful products from the residues of gas purification, and apparatus therefor. June 12.

7854. C. P. Armstrong. — From G. Jaunez. Apparatus for manufacturing carburetted air gas. June 19.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATION.

9371. F. C. Ostertag. — From L. Ferrario, Italy. Improvements in the process of and apparatus for treating heavy hydrocarbons. June 4.

COMPLETE SPECIFICATION ACCEPTED.

1888.

10,186. A. Campbell and W. Boyd. See Class II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

7977. S. Pitt. — From L. Casella and Co., Germany. The production of new bluish-black colouring matters. May 13.

8156. H. H. Lake. — From A. Leonhardt and Co., Germany, through Wirth and Co. Improvements in the manufacture of amido-phenols. May 16.

8264. H. H. Lake. — From A. Leonhardt and Co., Germany, through Wirth and Co. Improvements in the production of blue-black colouring matters. May 17.

8299. B. Willcox. — From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in or connected with the manufacture of azo-colouring matters for printing and dyeing. May 18.

8373. J. Y. Johnson. — From The Badische Anilin und Soda Fabrik, Germany. Improvements in preparing colouring matters of the oxyketone group suitable for dyeing and printing with the aid of mordants. May 20.

8548. E. de Pass. — From Messrs. Ewer and Pick, Germany. Process for producing azo-colouring matters from dehydrothiopatoluidine of 191° C. melting point, and from its homologue dehydrothiometaxyldine. May 23.

8673. B. Willcox. — From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in the manufacture of colouring matter and of leuco-bases employed therein. May 24.

8726. W. G. Thompson. The production of new azo-tetrazo-nitro- and nitroso compounds. May 27.

8732. W. G. Thompson. The production of compounds produced by the action of oxidising agents on phenols, naphthylamine, and on sulpho acids. May 27.

8750. B. Willcox. — From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in the manufacture of basic colouring matter. May 27.

9076. F. X. Best and R. Rice. An improved method of preparing dyes. May 31.

9384. H. D. Kendall. Improvements in the production of colouring matter from coal-tar products. Complete Specification. June 6.

9427. J. Y. Johnson. — From The Badische Anilin und Soda Fabrik, Germany. Improvements in preparing colouring matters of the oxyketone group, suitable for dyeing and printing with the aid of mordants. June 6.

9428. J. Y. Johnson. — From The Badische Anilin und Soda Fabrik. Improvements in preparing colouring matters of the oxyketone group, suitable for dyeing and printing with the aid of mordants. June 6.

9429. J. Y. Johnson. — From the Badische Anilin und Soda Fabrik. Improvements in the production of coloured compounds of gallacetophenone within or upon animal and vegetable fibres. June 6.

9489. F. Petersen. Improvements in the manufacture or production of colouring matters suitable for dyeing and printing. June 7.

9612. J. Y. Johnson. — From F. von Heyden, Germany. A new or improved manufacture of beta-naphthol carbon acid. June 11.

9642. O. Imray. — From The Farbwerke Vormal's Meister, Lucius, und Brüning, Germany. Production of oxysulphonic acids and naphthalin. June 11.

9643. O. Imray. — From The Farbwerke Vormal's Meister, Lucius, und Brüning. Improvements in the production of colouring matters from oxysulphonates of naphthalin. June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

10,314. J. Y. Johnson. — From The Badische Anilin und Soda Fabrik. Manufacture of methylene blue and allied colouring matters. May 22.

10,653. C. D. Abel. — From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of brown colouring matters which dye cotton without the use of a mordant. May 22.

10,845. H. H. Lake.—From K. Ochler. Manufacture of colouring matters. May 29.

13,798. O. Inray.—From G. C. Zimmer. Manufacture of colouring matters. June 12.

14,836. W. G. Thompson and W. H. Claus. Production of new colouring matters. May 22.

1889.

4565. H. H. Leigh.—From R. G. Williams. Colouring matters. June 12.

7587. A. Bang.—From Dahl and Co. Production of azo-colouring matters from diamidodibenzylbenzidin and diamidodibenzyltolidine. June 12.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

8106. V. Schevelin and P. Mindovsky. Process for the treatment of vegetable fibres by means of acid, neutral, and alkaline residues of naphtha manufacture, or specially prepared substances analogous to such residues. May 15.

9236. J. Palmer. A new and improved system of retting all gummy fibres. June 4.

9534. T. Rivett. Improvements in gassing yarns. June 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

10,633. W. Hitchcock-Spencer. Apparatus for treatment of rhea or China grass and other vegetable fibres. June 5.

1889.

5582. A. W. Montgomery. Treatment of sisal hemp. June 5.

6836. S. Cooper and T. Cooper, jun. Apparatus employed in the manufacture of wood wool. June 5.

7315. J. T. Pearson. Means and apparatus for humidifying fibrous substances. June 12.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

7948. E. M. H. Andreoli. See Class XI.

8107. V. Schevelin and P. Mindovsky. Process for cleansing and bleaching fibrous substances, and for fixing organic colouring matters thereon by means of acid and alkaline residues of naphtha manufacture or of specially prepared substances analogous thereto. May 15.

8237. T. Parkinson. Improvements in the methods of mordanting by drying cotton yarns and similar substances, and in the apparatus therefor. May 17.

8477. D. Walker and R. Walker (The Middleton Paper Staining Co.). Improvements in the method of and in means for printing designs in several colours at one operation upon paper, cloth, and other similar materials and fabrics. May 22.

9149. S. Mason, jun. Improvements in apparatus for dyeing and otherwise treating wool. June 3.

9254. J. Frost. Certain improvements in dyeing or colouring hair, wool, silk, fur and other animal or vegetable fibres in the raw or manufactured state. June 4.

9432. G. A. Greeven. Improvements in impregnating, washing, and dyeing yarn in hanks or skeins, and in the means or apparatus employed therein. June 7.

9692. A. Graemiger, W. T. Whitehead, S. Mason, jun., and E. A. Leigh. Improvements in machines for dyeing, bleaching, and otherwise treating yarn in cop or other compact form. June 12.

9836. W. E. Heys.—From C. Vandermeirssche, France. Improvements in the method of and apparatus for dyeing and similarly treating yarns and textile materials in all stages of preparation. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9044. C. Dratz and H. Dratz. Dyeing or painting on fabrics, and apparatus therefor. May 29.

11,452. J. C. Mewburn.—From La Société Leblois, Picéni et Cie. Bleaching, dyeing, &c. textile materials, and apparatus therefor. June 5.

11,806. E. Sutcliffe and G. E. Sutcliffe. Dyeing aniline black. June 5.

12,670. H. E. Hounsell.—From G. A. Conant. Bluing paper. June 12.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

8045. H. E. Newton.—From L. O'Brien. See Class X.

8177. E. Hermite, E. J. Paterson, and C. F. Cooper. Manufacture of bleaching and disinfecting liquor. May 16.

8537. A. J. Boulton.—From P. J. McMahon, United States. Improvements in or relating to the manufacture of anhydrous ammonia. May 22.

8741. W. P. Thompson.—From P. Magnier, France. Improvements in the manufacture of picric acid and certain alkaline or alkaline-earth picrates. May 27.

8779. J. J. Alsberge. Process for the manufacture of chlorine, which may be employed in combination either with the ammonia-soda process or with the Leblanc soda process. May 27.

8841. C. A. Burghardt. Improvements in the manufacture of nitrate of ammonium and of a resulting by-product. May 28.

8862. W. Thorp. Improvements in the method of and apparatus for condensing or absorbing and utilising sulphuric and sulphurous acid fumes. May 28.

8993. S. W. Wilkinson. See Class II.

9225. T. Turner. Improvements in the treatment of waste pickle from galvanising works. June 4.

9283. H. Goldschmidt. Improvements in extraction and use of metallic precipitates. June 4.

9680. A. G. Greenway. Improvements in the utilisation of waste acids or pickles formed in galvanising iron and called by him the "ammonium-sulphide process." June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9835. R. Weiss. Manufacture of acetic acid and by-products. June 5.

10,186. A. Campbell and W. Boyd. See Class II.

10,187. A. Campbell and W. Boyd. Obtaining chlorine from hydrochloric acid or chlorides, and regenerating the peroxide of manganese used. June 5.

10,193. G. H. Bolton, J. R. Wyld, and H. Auer. Manufacture of permanganates and chlorates. June 5.

10,322. J. Hargreaves. Treatment of sulphuretted hydrogen to obtain sulphur, and apparatus therefor. June 5.

11,731. C. N. Hake. Manufacture of nitrate of ammonia. June 19.

16,247. H. J. Kirkman. Utilisation of waste pickle from tinning and galvanising works where hydrochloric acid is used for pickling. May 29.

17,183. J. B. Thompson. Reduction of hydrogen sulphide for the production of sulphur therefrom. May 29.

1889.

5221. M. Cannon. Manufacture of acetic acid. June 5.

6443. E. Augé. Manufacture of soda alum. May 22.

6710. W. P. Thompson.—From J. A. Bradburn. Manufacturing caustic soda or caustic potash. May 29.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

7919. R. T. Grocott. Improvements in apparatus for making certain articles of pottery ware, such as electric lamp roses, switches, fuse blocks, and the like. May 13.

8049. T. Davidson. Improvements in pressed glass dishes and in their manufacture. May 14.

8166. J. McMillan. Apparatus for making bottles or other articles having a narrow orifice in glass, crystal, or similar molten metals, with a certain modification of same for making similar articles in clay, stone, flint, or china ware. May 16.

8403. W. J. Blenko. Improved process and apparatus for producing sheet glass with or without ripples or design or designs upon one surface. Complete Specification. May 21.

8511. E. Bassy. Improved compounds for the manufacture of bricks, tiles, and pottery goods in general, also in compounds or combination of ingredients for the manufacture of white enamel or opaque colours as a surfacing body or glaze to said bricks or articles. May 22.

8597. J. Stiel. A weather- and acid-proof enamel for building materials and the like, and a method of producing the enamel. Complete Specification. May 23.

8760. A. Drummond. Improvements in apparatus for manufacturing corrugated, ribbed, or other glass having designs or patterns upon the surface. May 27.

9147. J. W. Homer. Improved means or apparatus for withdrawing molten glass or molten metal from furnaces. June 3.

9148. F. E. Grosse. An improved process for manufacturing antique irising mother-of-pearl like blown, rolled, or pressed window glass. Complete Specification. June 3.

9257. H. T. Holloway and H. Holloway. Improvements in tile linings to walls and other upright partitions. June 4.

9645. H. J. Allison.—From C. C. Gilman, United States. Improvements in the manufacture of porous earthenware. Complete Specification. June 11.

9841. F. C. Clare. Improvements in the manufacture of terra-cotta porcelain castor bowls, knobs, and hands. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

11,016. H. J. Haddan.—From the Josephine Glass Works, Germany. Manufacture of red glass. June 12.

15,300. G. R. Grant. Pictures or decorative plaques formed largely of glass. June 19.

1889.

6393. P. Simson. Manufacture of plate glass. May 29.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

8042. A. Schöfer. A new or improved continuous lime and cement kiln or furnace. Complete Specification. May 14.

8145. G. P. Gildea. An improved method of making cement from chalk marls and argillaceous limestones, and of utilising poor clays for the purpose of making cement, and apparatus therefor. May 16.

8309. R. Stone. Improvements in the manufacture of fireproof plastic materials, applicable to various purposes. May 18.

8428. M. May. A process for producing artificial polished or ground stone. May 21.

8795. A. N. Ford. The manufacture of improved materials for roofing and other purposes, and of a composition therefor. May 27.

8922. J. Clarke. Improvements in or relating to kilns for burning bricks or the like. May 29.

9166. E. Nunan. Improved base for plastering and other purposes. June 11.

9843. J. Hadfield, A. J. Hadfield, and J. W. Hadfield. Improvements in the manufacture of asphalt, and in the apparatus used therefor. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9986. F. W. S. Stokes. Continuous manufacture of cement. June 5.

1889.

2844. A. C. Ponton, B. L. Mosely, and C. Chambers. Manufacture of artificial stone. May 29.

4175. E. Münjah. Producing useful materials from greenstone, diabase, and other varieties of hornblende. May 29.

5190. St. G. T. C. Bryan. Treatment of slag to make it suitable for pavements, walls, &c. May 29.

6584. G. R. King. Compounds to restrain the setting of plaster, &c. June 5.

8042. A. Schofer. See application above. June 19.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

7971. J. T. Blomfield and W. D. Bohm. Improvements in the separation of metals and substances contained in same. May 13.

8038. H. H. Lake.—From E. Thomson, United States. Improvements relating to the welding, soldering, or brazing of metals, and to apparatus therefor. Complete Specification. May 14.

8045. H. E. Newton.—From L. O'Brien, New South Wales. A new or improved process for making metallic sulphates in solution. Complete Specification. May 14.

8057. The Alkaline Reduction Syndicate, Lim., and A. B. Cunningham. Improvements in the production of sodium, and in apparatus therefor. May 14.

8297. F. Bachschmid. Improvements in inlaying metals. May 18.

8438. T. Slater. An improved method of coating wrought or cast iron with a metallic alloy made especially for the purpose intended, the said alloy being applicable to various articles where brass is now used. May 21.

8150. W. Sowerby. Improvements in the treatment of iron, steel, and other metals in the making of cylinders, shafts, ingots, and other articles for effecting the consolidation thereof. May 21.

8492. J. Riley. Improvements in the manufacture of steel or steel-like compounds. May 22.

8543. T. Twynam. Improvements in effecting the re-carburisation of steel or ingot iron. May 22.

8605. G. C. Fricker. Preparing metallic sheets for coating with other metals. May 23.

8608. R. L. Cousins. A process and apparatus for extracting precious metals from ores or quartz. May 23.

8630. A. Crosbie. The recovery of tin from tin plate, scrap, &c. May 24.

8678. M. R. Conley and J. H. Lancaster. Improvements in apparatus for deoxygenising, dephosphorising, desulphurising, and treating iron and other ores, and for collecting and burning the fumes and gases therefrom. May 24.

8789. M. Crawford. Improvements in means for effecting the separation of particles of different specific gravities, more especially intended for the separation of gold and other metals from crushed or divided ores. May 27.

8822. E. Matheson. An improved process of manufacturing pots or crucibles of wrought iron or other malleable metals. May 28.

8856. H. H. Lake.—From C. M. Ball, S. Norton, and A. T. Porter, United States. Improvements relating to the separation of magnetic ores from phosphorus and other impurities, and to apparatus therefor. Complete Specification. May 28.

8883. C. A. Doremus. Process for removing calcium, magnesium, and other metals from aqueous solutions. Complete Specification. May 28.

8943. T. Twynam. Improvements in the manufacture of ingot iron and steel. May 29.

9006. E. A. Cowper. Improvements in the manufacture of Bessemer steel. May 30.

9140. G. Hatton. Improvements in the manufacture of iron and steel, and in apparatus employed therein. June 3.

9147. J. W. Horner. See Class VIII.

9187. H. H. Chandler. An improved flux for coating iron or steel with copper and for welding copper. Complete Specification. June 3.

9206. J. T. King.—From W. R. Jones, United States. Improvements in the manufacture of iron and steel, and in apparatus therefor. Complete Specification. June 4.

9289. W. F. M. McCarty, W. H. Ashton, and H. D. Walbridge. Improvements in and relating to a process of and apparatus for producing steel direct from the ore. Complete Specification. June 4.

9301. J. Gill. Improvements in blast furnaces. June 4.

9358. R. E. Green. Improvements in the production of alloys of aluminium. June 4.

9472. E. W. T. Jones. Improvements in preparing surfaces of iron and steel for receiving a coating of metal or alloy, such as spelter, tin, or terne metal. June 7.

9476. A. A. Lockwood and H. Chappel. Improvements in the treatment of auriferous and argentiferous materials, and in apparatus therefor. Complete Specification. June 7.

9592. S. Alley. Improvements in apparatus for treating metallic ores or compounds with chemicals. June 11.

9632. T. Parker. Improvements in and in connexion with pickling and preparing iron for galvanising. June 11.

9646. A. J. Boulton.—From J. M. Dufort and V. E. J. Dufort, France. Improvements in the manufacture of articles in cast metal with a coating of other metal. Complete Specification. June 11.

9784. W. White. Improvement in the distillation of sodium and potassium and their alloy. June 14.

9821. J. Shears. The extraction of metals from ores and slags and the debris from smelting works and other manufacturing works. June 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8095. B. H. Thwaite. Producing solid steel castings, and apparatus therefor. June 12.

8303. W. F. Donkin.—From R. Donkin. Amalgamation of gold and other ores, and apparatus therefor. May 29.

8332. W. P. Thompson.—From H. F. Julian. Treatment of ores for the extraction and recovery of gold and silver, and apparatus therefor. June 12.

8747. L. Q. Brin. Producing aluminium bronze and other alloys of aluminium. May 22.

9391. W. G. Forster. Manufacture of sodium and potassium. May 29.

9457. G. Theodossieff. Tempering or hardening steel or iron. May 29.

10,266. J. A. Stephan and R. Southerton. Manufacture of aluminium and its alloys. May 29.

11,691. T. Andrews. Apparatus for consolidating small iron or steel scrap. June 12.

17,623. H. J. Kirkman. Utilisation of flux skimmings from galvanising works. June 19.

17,909. A. J. Boulton.—From W. Ross and H. D. Bush. Upsetting of metals, and apparatus therefor. May 29.

1889.

1602. M. Johnson, W. E. Field, and J. S. Berman. Amalgams, and method of applying same in the amalgamation of gold and silver. June 19.

2722. E. L'Homme. Metallic alloys. June 12.

5669. C. M. Hall. Production of aluminium. June 5.

5670. C. M. Hall. Production of aluminium and alloys thereof. June 5.

6070. S. McCloud. Manufacture of bars and rounds of steel and iron, and apparatus therefor. May 29.

7132. L. Imperatori. Manufacture of compressed compound blocks of substances containing iron and of carbonaceous matter, and the use of such blocks in the production of cast steel and ingot iron. June 5.

7181. E. Walsh, jun. Method and apparatus for condensing zinc vapours and collecting the metallic zinc therefrom. June 5.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

7948. E. M. H. Andreoli. Improvements in bleaching paper pulp by electrolysis. Complete Specification. May 13.

8476. T. Parker. Improvements in the method of cleansing iron for galvanisation and similar purposes. May 22.

8552. G. Nahusen. An improved process for the electrolytic separation of aluminium, aluminium alloys, and magnesium from solutions of their salts. May 23.

8709. E. H. M. Andreoli. Amalgamating gold by electricity and mechanical motion. May 27.

8855. T. Harris and H. F. de Bathe Cameron. Improvements in secondary batteries or accumulators. May 28.

8925. C. Wells. Improvements in electric batteries. May 29.

8986. D. Urquhart, W. Bates, and F. Wynne. Improvements in secondary batteries. May 30.

9093. A. Jung. Improvements in storage batteries. June 1.

9153. D. J. Arnold and H. B. Coryell. An improved dry galvanic battery. Complete Specification. June 3.

9183. M. Sussmann. An improved exciting liquid for electric batteries. June 3.

9237. G. E. Dorman. Improvements in dynamo-electric generators and motors. June 4.

9659. A. H. Norman. Improvements in and connected with electric batteries. June 11.

9667. G. Wilkinson. Improvements in apparatus for the generation of electricity. June 12.

9681. R. Tatham. Improvements in electrical storage or secondary batteries. June 12.

9828. W. J. S. Barber-Starkey. Improvements in secondary voltaic batteries. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8161. C. C. Nichols, for the London Electric Bleaching Co. Bleaching paper-pulp by electricity. June 12.

11,569. H. Pieper. Secondary and other electric batteries. June 19.

19,061. A. Cornwell. Materials to be used in galvanic batteries. May 22.

1889.

6112. P. A. Newton.—From W. Main. Secondary batteries. May 22.

6119. J. J. Shedlock and R. Me-stern. Thermo-electric batteries. May 22.

6865. G. E. Heyl. Secondary batteries. May 29.

7002. T. H. Hicks. Secondary or storage batteries. June 5.

7356. C. Maltby-Newton. Galvanic or primary batteries. June 12.

7619. W. J. Starkey Barber-Starkey. Electric batteries. June 12.

7647. S. S. Wheeler. Electric motors and dynamo-electric machines. June 12.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

8196. R. O. Unglaub. Improved apparatus for rectifying glycerin. Complete Specification. May 16.

8567. J. Taylor. An improvement in the manufacture of soap powder. May 23.

8740. W. P. Thompson.—From A. Schumacker and C. Tschiffeli, France. Improvements in or appertaining to presses for extracting oil or other liquids from seeds or the like. May 27.

9201. J. Snowden. Improvements relating to toilet and cleansing soaps. June 3.

9207. J. C. S. McLay and J. A. Fisher. Improvements in the manufacture of cleansing and polishing materials. June 4.

9382. E. Cuvelier. A new or improved process for crushing and extracting oil or liquids from oleaginous seeds and other like materials, and apparatus therefor. Complete Specification. June 4.

9400. T. R. Weston. An improvement in the manufacture of soap and similar substances. June 6.

9410. A. H. Parker. Improved cleansing, scouring, and bleaching compound for wool and other fabrics, also applicable to cleansing purposes generally. June 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9123. T. S. Steen. Manufacture of soap. May 29.

10,296. M. V. Brisset. Purification of fatty acids, and apparatus therefor. June 5.

11,505. C. Weigelt. See Class XV.

1889.

4190. C. Hervieux and V. Bédard. Composition for use as axle grease. May 22.

4651. H. C. Foulsham. An improved soap powder. May 22.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

8362. T. S. Steen. An improvement in the manufacture of blacking for boots, shoes, and other leather articles. May 20.

8513. T. Hughes. An improved means for the protection of ships' bottoms, as also the inside of the vessels and other submerged substances, also for roofing structures and buildings and for inside decorations. May 22.

8910. W. Walker, J. Sloan, and E. W. Bell. Improvements in anti-fouling and anti-corrosive compositions. May 29.

9184. E. Mourlot. An improved varnish. June 3.

9436. J. Fleming. An improved paint. June 7.

9442. M. Williams and J. Ascough. Improvements in the manufacture of blue colouring matter for laundry bleaching and other purposes. June 7.

9565. H. Noerdlinger. An improvement in the manufacture of oil varnish. June 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

10,192. J. Eastman. Preservative material for iron, steel, or other structures, and the bottoms of vessels, and process of manufacturing it and other products from gas tar. June 19.

10,301. E. Oates. Varnish-removing compound. May 29.

10,365. E. Oates. Paint-removing compound. May 29.

10,757. F. Wendling. New paint for stones, plaster, &c. June 5.

11,398. P. Brentini. Compound for removing paint. June 12.

11,579. S. B. Beswick. Varnish for cleaning and preserving harness. June 12.

1889.

1282. J. B. Hannay. Making a white pigment of lead, and apparatus therefor. May 29.

1434. J. B. Hannay. Purifying sulphate of lead. June 5.

5380. G. R. B. Kempton. Sapphire crystal blue for laundry purposes. June 5.

5792. L. E. Andés. An enamel or paint having disinfecting properties. May 22.

6581. G. Hand Smith. Treatment of gum copals, gum resins, and other gums for the manufacture of varnishes and other solutions. June 5.

7379. W. Smartt. Production of vulcanised india-rubber and analogous materials. June 12.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

8191. J. Kristen. Improvements in the process of and means for dyeing hides. May 16.

8194. H. B. Bury, J. Bury, and J. I. Davies. A process for removing grease from sheep and lamb pelts before fleshing and splitting. May 16.

8590. R. North and W. Ellis. Improvements in apparatus for "grounding" chamois and other leathers. May 23.

9776. B. Nicholson and T. Palmer. Improvements in and apparatus or means for the tanning of hides, skins, or other leather goods. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

10,362. P. Puech. Process for unhairing skins. June 5.

1889.

5671. C. W. Cooper. Process and apparatus for treating hides, skins, or scraps in liquids. May 22.

5672. C. W. Cooper. Method of treating hides, skins, or scraps in liquids. May 22.

XV.—AGRICULTURE AND MANURES.

APPLICATIONS.

8782. A. Booty. An improved manurial composition or stimulant for plants, bulbs, trees, and other vegetable produce. May 27.

9087. J. W. Lodge. An improved process and means to be employed for partially destroying and mixing night-soil and other refuse, and for converting the same into manure suitable for grass land and arable purposes. June 1.

COMPLETE SPECIFICATION ACCEPTED.

1888.

11,505. C. Weigelt. Preparation of manures from fish, &c., and extraction of oil therefrom. May 22.

XVI.—SUGARS, STARCHES, GUMS, ETC.

APPLICATIONS.

8052. C. Steffen. Apparatus for refining loaf sugar in the moulds. Complete Specification. May 14.

8596. J. G. Chapman. Improvements in and connected with apparatus for evaporating and concentrating saccharine or other solutions. May 23.

8622. C. Steffen. An improved apparatus for producing white sugar. Complete Specification. May 24.

9021. J. Foster. Improvements in and relating to the drawing off and condensing of the vapour from sugar pans, and apparatus therefor. May 30.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9320. A. H. J. Bergé. The acid saccharification of amylaceous substances. May 29.

1889.

7131. H. A. Hughes. Process and apparatus for obtaining sugar liquor from sugar cane, or for obtaining extract. June 19.

8052. C. Steffen. See application above. June 19.

XVII.—BREWING, WINES, SPIRITS, ETC.

APPLICATIONS.

7964. R. Haddan.—From J. C. Severino, Spain. A method of manufacturing a novel liqueur or beverage. Complete Specification. May 13.

8277. J. Leslie. The application of oxygen in the distillation of alcoholic liquids. May 18.

8343. L. A. Enzinger. An improvement in apparatus for sterilising fermented alcoholic liquors. May 20.

8686. M. Bauman, T. Sederl, and F. Wirk. Improvements in malt-kilns and kilns for drying similar materials. May 24.

8839. C. Huelser.—From J. Kuntze. A new or improved apparatus for pneumatic malting. May 28.

8992. W. W. Mutter and W. Dawson. Improvements in or relating to distillers' safes. May 30.

9181. E. Luck. Improvement in and apparatus for the purification of alcohol or alcoholic liquors. June 3.

9276. A. Gough, sen. Improvements in the apparatus for the making and drying of malt. June 4.

9280. S. Hirschler. An improved apparatus for agitating or turning over malt and other like substances. June 4.

9321. F. M. Maynard. An improved valve and fittings for the better regulation of the flow of steam or liquids for various purposes, especially designed for use with brewers' and distillers' attenuators, &c. June 4.

9629. J. D. Paul. A new method of preserving beer. June 11.

9660. J. Phillipi. A new or improved process of and apparatus for pasteurising, cooling, and aerating beer or other fermented or fermentable liquids, and filling the same into casks. June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8116. E. Wilson. Drying and curing malt, hops, &c. by an improved apparatus. June 5.

9964. Baron S. Stempel and N. Warcuzoff. Purification of alcohol. May 22.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

8882. W. P. Branson and H. W. Neild. Improvements in evaporating or condensing milk and other liquids. May 28.

8945. J. L. Johnston. Further improvements in the preparation and combination of animal substances with vegetable substances for use in food. May 28.

8963. T. Williams. Improved means for smoke-curing fish and flesh foods, and in fuel compounds for the purpose. May 29.

9226. B. Johnson. An improved mode of preserving fruit. June 4.

9303. T. D. Coustas. Improvements in preserves and condiments. June 4.

9348. E. J. T. Digby. Improvements in the preparation and manufacture of an alimentary compound. June 4.

9861. C. Heinemann. The manufacture of a malt product called "wheat coffee." June 15.

9881. A. Richardson. Improvements in the preservation of milk in bottles. June 15.

B.—Sanitary Chemistry.

8088. C. H. Beloe and F. Candy. Improvements in and connected with the purification and filtration of sewage and other foul liquids. May 15.

8294. H. R. Newton. Improved means for filtration and disposal of sewage and other offensive liquids. May 18.

8725. A. K. Brown. Improvements in or connected with apparatus for softening, purifying, clarifying, and filtering water and other liquids. May 27.

9763. G. Brownen and J. Gamgee. Improvements in bleaching, disinfecting, purifying, and preserving substances, and apparatus therefor. June 13.

9777. B. Nicholson and T. Palmer. Improvements in and apparatus for the treatment of sewage, faecal matter, foul waters, or the like, for the purification or deodorising thereof, and the obtaining of products therefrom. June 13.

9793. J. Croft and J. F. Yeadon. Improvements in the method of purifying water and extracting sludge and other refuse therefrom. June 14.

C.—Disinfectants.

8177. E. Hermite, E. J. Paterson, and C. F. Cooper. See Class VII.

8527. W. Black and W. L. Remoldson. Improvements in the manufacture or preparation of disinfectants or antiseptics. May 22.

9165. A. H. Allen and W. W. Staveley. Improvements in the production and application of the metallic compounds of phenoloids. June 3.

9256. J. Shaw. Purifying sewer-gas, and ventilating sewers, drains, and water-closets, &c.—a deodoriser. June 4.

COMPLETE SPECIFICATIONS ACCEPTED.

B.—Sanitary Chemistry.

1888.

8491. J. Price. Expelling liquid from and compressing sewage sludge and other semi-fluid or plastic substances. May 22.

C.—Disinfectants.

1889.

4387. H. Oppenheim. Tablets for disinfecting, antiseptic, medical, bleaching, and laundry purposes, and as an insecticide. May 29.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

7948. E. M. H. Andreoli. See Class XI.

8509. F. Favier, jun. Improvements in machinery for refining and finishing half-stuff in paper making, and in hydrostatic balances for changing the contents of the pulp reservoirs. Complete Specification. May 22.

8514. F. J. Fawcus. Improvements in the manufacture of paper. May 22.

8903. J. Groome. Improvements in machines used for reducing or pulping materials used in the manufacture of paper. Complete Specification. May 29.

8946. J. Husnik. Improvements in the production of semi-transparent marks or designs on or in paper by means of gelatin relief printing. Complete Specification. May 29.

9313. G. F. Gregory. Making paper for taking press copies untearable. June 4.

9694. F. J. Cheesebrough. From H. Pataky and W. Pataky, Germany. Manufacture of wood pulp. Complete Specification. June 12.

COMPLETE SPECIFICATION ACCEPTED.

1889.

2702. E. C. de Mejer and T. Greenwood. Manufacturing artificial stucco-work. May 29.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

8085. H. W. Jones. Improvements in the production of developers for photographic use. May 15.

8899. T. Thorns. Rendering albumenised and sensitised photographic paper free from smell. May 29.

9012. A. H. Cros. Improvements in colour photography. Complete Specification. Date applied for under Patents Act, 1883, sec. 103, 8 November 1888, being date of application in France.

9520. J. H. Smith. The delivery and regular distribution of gelatino-bromide of silver or other emulsion, or viscous liquid upon glass, paper, or other plane surface. June 8.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

8718. Sir F. A. Abel and J. Dewar. Manufacture of explosives. May 27.

9361. A. V. Newton.—From A. Nobel. Improvements in the preparation of explosive compounds. June 4.

9433. W. B. McGavin. Improvements in explosive compounds. June 7.

COMPLETE SPECIFICATION ACCEPTED.

1888.

11,751. C. Lamm. Protecting and preserving explosives. June 19.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 7.—VOL. VIII.]

JULY 31, 1889.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2 6.

The Society of Chemical Industry.

ASSISTED BY THE FOLLOWING STAFF OF

Abstractors:

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

T. L. Bailey, Ph.D.
G. H. Beckett.
D. Bendix.
E. Bentz.
E. E. Berry.
E. J. Bevan.
Bertram Blount.
Arthur G. Bloxam.
C. H. Bothamley.
E. G. Clayton.
Julius B. Cohen, Ph.D.
C. F. Cross.
A. R. Davis.
W. W. Haldane Gee, B.Sc.
C. Napier Hake.
S. Hamburger, Ph.D.
Oswald Hamilton.
John Heron.
Bertram Hunt.
C. C. Hutchinson.
D. E. Jones, B.Sc.
W. E. Kay.
A. J. King, B.Sc.

F. S. Kipping, D.Sc.
Chas. A. Koln, Ph.D.
F. W. T. Krohn.
T. A. Lawson, Ph.D.
J. Walter Leather, Ph.D.
A. Liebmann, Ph.D.
D. A. Louis.
W. Macnab.
J. M. H. Munro, D.Sc.
H. S. Pattinson, Ph.D.
H. T. Penternmann.
S. G. Rawson, D.Sc.
A. Rée, Ph.D.
F. W. Renaut.
Edward Simpson.
A. J. Smith, B.Sc.
Oscar J. Steinhart, Ph.D.
A. L. Stern, B.Sc.
A. Studer, Ph.D.
Bertram Thomas.
Eustace Thomas.
V. H. Veley, M.A.
R. Lloyd Whiteley.
A. Wingham.

COUNCIL FOR YEAR ENDING JULY, 1890.

President: Sir Lowthian Bell, Bart., F.R.S.

Vice-Presidents:

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schmuck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

Ordinary Members of Council:

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Brock.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Hirtner.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brunner.	Ludwig Mond.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roscoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. J. J. Hummel.	A. Norman Tate.
	Thomas Tyrer.

Editor:

Watson Smith, The Owens College, Manchester.

NOTICES.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Post Office Orders in payment of subscriptions should in all instances be made payable at the General Post Office, London.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Society's Office will be closed from the 5th to the 14th August inclusive.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 10th JULY, 1889.

Berry, G. F., Atlas Chemical Works, West Ferry Road, Millwall, E., works manager.

Cowan, Lt.-Col. and Alderman Phineas, 15, Lancaster Gate, Hyde Park, W., soap maker and sugar refiner.

Holliday, Jas. R., 4, Bennett's Hill, Birmingham, solicitor.

Kempson, Jno. F., Pye Bridge Chemical Works, near Alfreton, Derbyshire, chemical manufacturer.

Mawdsley, Peter A., 8, Eaton Road, Chester, alkali manufacturer.

Orndorff, Dr. Wm. R., Cornell University, Ithaca, N.Y., U.S.A., instructor in chemistry (on U.S. Commission to Paris Exhibition).

LIST OF MEMBERS ELECTED, 23rd JULY, 1889.

Babington, Percival, Owens College, Manchester, analyst.

Ball, Arthur, c/o Messrs. Burroughs, Wellcome, and Co., Snow Hill Buildings, E.C., pharmaceutical chemist.

Brennan, Edmund J., P.O. Box 419, Johannesburg, S.A.R., mining agent.

Chamberlain, H. G., 22, Forest Drive West, Leytonstone, E., isinglass merchant.

Cronquist, Albert W., Royal Wharf, Skeppsholmen, Stockholm, Sweden, lecturer in Government Torpedo School.

Ewens, Paul, 87, Shirland Gardens, Maida Vale, W., civil engineer.

Gent, Wm. Thos., Misterton, Gainsboro', analytical chemist.

Hall, Robt. E., c/o Box 407, Johannesburg, S.A.R., assayer.

Hartmann, Dr. Wm., 186, Suffolk House, Cannon Street, E.C., chemist.

Hugill, Francis J., Rosedale, Lubbock Road, Chislehurst, Kent, manufacturing chemist.

Lewkowitch, Dr. Julius, Whitehall Soap Works, Leeds, manufacturing chemist.

Little, Wm. G., Blendon Cottage, Bexley, Kent, chemical manufacturer.

Ostlere, Edward, Messrs. Barry, Ostlere, & Co., Kirkcaldy, N.B., linoleum manufacturer.

Pielsticker, Carl M., Suffolk House, Cannon Street, E.C., engineer.

Pratt, Walter E., Chemical Laboratory, Midland Railway Co., Derby, analytical chemist.

Searl, Albert, c/o Messrs. Howards and Sons, City Mills, Stratford, E., analyst.

Staniland, Alf. E., 7, Nicholas Lane, London, E.C., cement manufacturer.

Wood, Jas., Stockwith-on-Trent, Gainsborough, engineer.

CHANGES OF ADDRESS.

Archbutt, L., 1/o Rose Hill; 11, Charnwood Street, Derby.

Bailey, Walter P., 1/o Silvertown; 8, South Park, Ilford, Essex.

Barber, Geo., 1/o 23; 27, Studley Road, Forest Gate, E.

Bell, Geo., 1/o Runcorn; 59, Sandown Lane, Wavertree Road, Liverpool.

Bramwell, Major E.; Journals to Navigation Chemical Works, St. Helens.

Cameron, Ian, 1/o Lisbon; retain Journals until further notice.

Crawford, D., 1/o Caldercruix; Ferryfield Printworks, Alexandria, N.B.

Edmonds, H. R., 1/o East 28th Street; 532, West 20th Street, New York, U.S.A.

Hastings, Hugh, 1/o Bradford; Woodford Cottages, Chester Road, Kidderminster.

Herroun, E. F., 1/o Deptford; Riverdale, Humber Road, Westcombe Park, S.E.

Joynson, F., 1/o Edgbaston; Clock Face, near St. Helens.

Mackinnon, A. K., 1/o Drayton Gardens; 105, St. George's Road, S.W.

Miller, Geo., 1/o Bold; c/o Widnes Alkali Co., Ltd., Widnes.

Naef, Dr. P., 1/o Zurich; Wymington Park, Northwich.

Quibell, Oliver, 1/o High Field; Magnus Lodge, Newark-on-Trent.

Redwood, Boverton, 1/o Gracechurch Street; 4, Bishopsgate Street Within, E.C.

Redwood, Robt., 1/o Gracechurch Street; 4, Bishopsgate Street Within, E.C.

Reed, Albert E., 1/o Cardiff; Highdene, Station Road, Sidcup, Kent.

Staub, Dr. A., 1/o Northwich; Sand, Glarus, Switzerland.

Waché, Alfred, 1/o Douai; 11^{Bis} Rue Nain, Ronbaix, France.

Watson, J. Cecil, 1/o Birchvale; c/o Daniel Lee & Co., Castleton, Manchester.

Williams, M. W., 1/o Ponders End; 4, Grove Gardens, Regent's Park, N.W.

TEMPORARY CHANGES OF ADDRESS.

Chase, Prof. Roscoe L., July No. to 11, Varnum Avenue, Pawtucketville, Lowell, Mass., U.S.A.

Johnston, W. G., July No. to c/o A. Burns-Glen; 8, Great Winchester Street, E.C.

PROCEEDINGS

OF THE

EIGHTH ANNUAL MEETING.

THE Annual General Meeting of the Society was held on Wednesday, the 10th July, in the theatre of the Royal Institution, London.

The President, Mr. LUDWIG MOND, took the Chair at 11 o'clock, and called upon the Secretary to read the Minutes of the last Annual Meeting. These having been duly confirmed, Mr. Henry Brunner proposed and Dr. D. B. Hewitt seconded, that Mr. Ivan' Levinstein and Mr. A. H. Allen should be appointed scrutators, to examine and report upon the ballot papers for election of new Council.

Mr. E. C. C. STANFORD inquired whether this course was necessary, seeing that the election was already practically settled by the number of nominations being equal to the number of vacancies. After some further discussion, it was decided that the procedure prescribed by the bye-laws ought to be followed, and the resolution was carried.

The General Secretary then read—

THE REPORT OF THE COUNCIL.

THE Council has the honour to report that the membership of the Society has increased from 2,395, as reported at the last meeting, to 2,445, or a net increase of 50 members. During the year 223 members have been elected, and 173 have been removed by death, resignation, and other causes.

The losses by death have been unusually heavy, and include the following names eminent in pure and applied science:—Dr. J. Peter Griess, F.R.S., the discoverer of the azo-compounds; Dr. Wm. Wallace, City Analyst of Glasgow, an authority on sanitation; J. J. Coleman, Chairman of the Glasgow and Scottish Section, the inventor of the Bell-Coleman mechanical dry air refrigerator; R. D. Silva, Professor of Analytical Chemistry at the Ecole Centrale, Paris; John Williams, a Vice-President of our Society, and at one time President of the Pharmaceutical Society, an authority of great weight in pharmacy, and one whose genial presence and counsel we greatly miss; Dr. Warren De la Rue, F.R.S., a former President of the Chemical Society, whose researches in chemistry, electricity, and astronomy are historical; Dr. R. S. Newall, F.R.S., identified with the invention of wire rope and the manufacture of submarine cables; and Dr. John Percy, F.R.S., late President of the Iron and Steel Institute, author of "Percy's Metallurgy."

During the year 55 papers and 5 communications have appeared in the Journal. Our thanks are due to those who have favoured the Society by reading these papers.

The Journal daily increases in importance as a work of reference, and every effort is made by the Publication Committee to add to its value. Within the last few weeks Mr. Watson Smith has arranged to give up his lectureship at the Victoria University, and, taking up his abode in London, has agreed to make the editing of the Journal his main occupation, and this on terms which, after full

deliberation, have been deemed satisfactory. The Council hopes that, in securing for the future his services, which have been so valuable in the past, it has promoted the best interests of the Society in whose continued prosperity the Journal is so important a factor.

This step has been rendered possible by the satisfactory state of our finances. On the 21st June last the Treasurer reported the sum of 3,688*l.* 15*s.* 9*d.* invested and 1,211*l.* 4*s.* 5*d.* in the Bank, as against 2,088*l.* 11*s.* 9*d.* invested and 1,761*l.* 12*s.* 9*d.* in the Bank a year ago. The Revenue last year, as will be seen from the balance sheet, amounted to 918*l.* 14*s.* 9*d.* more than the expenditure; due mainly to increased profit from advertisements in the Journal, and economies in printing and publishing effected without in the least detracting from the quality of the Journal. This year the profits from advertisements will be less, as the Council has agreed to accept a lower sum on the representation of the publishers, who had over-estimated the returns from this source.

The increased salary of the Editor under the arrangement alluded to above, the cost of providing further office accommodation, the cost of housing and binding the books presented by Mr. Raphael Weldon, referred to in the last report, and the improbability of large accessions of members in the future, render this surplus most welcome, and we are thus enabled to face the future with confidence and hope.

Among minor matters connected with the Journal, the following may be mentioned:—A new class called "Photographic materials and processes" has been added to the Journal and Patent Literature, the code of rules for those engaged in the production of the Journal has been revised, the Journal is now printed in uniform type throughout, and we shall publish at the end of 1890 a collective subject-matter index of the first nine volumes.

The adoption of the Report was moved by Dr. Hugo Muller, seconded by Col. Gamble, and carried unanimously.

The Honorary Treasurer (Mr. E. RIDER COOK) then presented the accounts for the year, published on page 504. He urged members to avail themselves more fully of the system of paying their subscriptions by bankers' orders. Those members who omitted to send in their subscriptions promptly were deprived of their Journals solely through that carelessness so common to busy men in dealing with private matters. The Society did not suffer, because the subscriptions always arrived eventually; but as bankers were willing to collect subscriptions, members might surely avail themselves more fully of the convenience. He would also ask members to bear in mind that at the beginning of every year, especially during January, the work of his department was very heavy, and that it was impossible for him, without a special staff, to acknowledge all subscriptions the moment they came in. He had received certain letters of complaint on the subject, but he was sure that when they knew the circumstances, members would make due allowance for slight delays occurring at such moments of pressure. He was glad to report that, although the Council had invested 1,500*l.* during the year, he had now in hand over 1,200*l.*, which was quite enough to meet expenses until the subscriptions for next year came in.

THE PRESIDENT moved that a vote of thanks be tendered to Mr. Rider Cook for the care and skill with which he had filled the position of Hon. Treasurer for eight years. He was sure that it was unnecessary for him to go into any details on the subject, and hoped that the vote would be carried by acclamation.

Mr. JOHN SPILLER seconded the motion, which was carried by acclamation.

THE HON. TREASURER in returning thanks said that he considered himself an exceedingly fortunate official. The duty of a treasurer was usually to supply funds; but this Society was so prosperous that he had only to take care of and invest its money. That was an exceptional position, and one which it was a gratification to hold.

STATEMENT OF REVENUE AND EXPENDITURE FOR THE YEAR 1888.

* In addition to this there is an amount of £2088 11s. 7d. Metropolitan 3% Consolidated Stock, invested in the names of Mr. David Howard and Mr. Edward Rider Cook.

We have compared the above Statement with the Receipts, Counterfoils, Vouchers, and Books of the Society,
and certify it as correct.

(Signed) THEOBALD BROS. & MIALL,
Chartered Accountants.

ELECTION OF AUDITORS.

Mr. G. H. MAKINS moved that Messrs. Theobald Bros. and Miall, Chartered Accountants, be re-elected auditors for the ensuing year. The motion was seconded by Mr. John Pattinson and carried unanimously.

ANNUAL GENERAL MEETING FOR 1890.

Professor CLOWES said that he deeply regretted the unavoidable absence of the Chairman of the Nottingham Section, from whom he had just received a telegram asking him to explain his inability to attend for the purpose of inviting the Society to hold its General Meeting at Nottingham next year. In conveying that invitation to the Society at large, he was happy to be able to say that the Council had already received it with approval. Members would be aware that Nottingham was centrally placed and well served with railways. Though there was not much chemical industry in the town itself, there was the lace and hosiery manufacture, which would be found interesting by some members; and there was also the tannery of Sir John Turney (Chairman of the Section), which was one of the largest in the country. Beyond this, however, he hoped that there would be an attractive programme of visits to places within easy reach of Nottingham. Some of the Burton brewers had already expressed their willingness to entertain members; and he did not doubt that Sheffield would be willing to show them something of the iron and steel industries. With regard to the lighter part of the programme, he was sure that if the meeting were disposed to accept the invitation, Nottingham would try to maintain its reputation for hospitality, and do its best to make the visit pleasant and interesting to all who should attend.

The motion was seconded by the President elect (Sir LOWTHIAN BELL, Bart., F.R.S.) and carried by acclamation.

THE PRESIDENT'S ADDRESS.

At the inaugural meeting of our Society held in London eight years ago, I had the honour to read a paper on the "Patent Laws, with special reference to Chemical Inventions." In this paper I made the following remark:—

"Science tells us how very far we are from attaining our industrial aims with anything approaching the theoretical expenditure of force. Science also tells us in what directions we may look forward to arriving at improvements. I might say that we are on the eve of creating a science of invention, that is, of developing scientific methods for solving industrial problems."

As exemplifying to a certain extent the application of methodical research to an industrial problem, I propose to bring before you to-day an account of the work I have been engaged in for many years in relation to the procuring of new and abundant supplies of ammonia, and to investigations connected therewith.

Through the classic researches of Lawes and Gilbert, who proved, in opposition to no less an authority than Liebig, that ammonia is a most valuable manure which enables us not only to maintain, but to multiply the yield of our fields, and thus to feed on the same area a much larger number of inhabitants, the immense importance of an abundant supply of ammonia, more particularly for the Old World, with its teeming population and worn-out soil, has been apparent to every one.

For many years Europe has paid to South America millions upon millions of £s for ammonia in the shape of guano, and more recently, since the supply of guano practically ceased, for nitrate of soda, which effectually serves same purpose as ammonia. During the past year South America exported 750,000 tons of nitrate, of which 650,000 went to Europe, representing a value of not less than 6,500,000*l*.

The problem of saving this immense expenditure to Europe, of making ourselves independent of a country so far away for the supply of a material upon which the prosperity of our agriculture—our most important industry

—depends, by supplying this ammonia from sources at our own command, is certainly one of the most important which our science has to solve.

It is more than 100 years since Berthollet ascertained that ammonia consists of nitrogen and hydrogen, two elements which we have in great abundance at our command; and innumerable attempts have been made during this century to produce this valuable product by the direct combination of the elements, as well as by indirect means. It has been equally well known that we are in possession of three abundant sources of nitrogen:—

- (1.) In the shape of matter of animal origin.
- (2.) In the shape of matter of vegetable origin.
- (3.) In the atmosphere, which contains no less than 79 per cent. of uncombined nitrogen.

In olden times ammonia was principally obtained from animal matter, originally in Egypt by the distillation of camel dung, later on from urine, and from the distillation of bones and horn. The quantity so obtained was very small and the products very expensive. The introduction of coal gas for illumination gave us a considerable and constantly increasing supply of ammonia as a by-product of the gas manufacture, and until recently all practical efforts to increase our supply of ammonia were directed towards collecting and utilising in the best possible manner the ammonia so obtained. The immense extension of the coal gas industry all over the world has in this way put us into possession of a very considerable amount of sulphate of ammonia, amounting in Europe now to 110,000 tons per annum. In recent years this has been augmented by the ammonia obtained by the distillation of shale, by the introduction of closed ovens for the manufacture of coke, combined with apparatus for condensing the ammonia formed in this manufacture, and also by the condensation of the ammonia contained in the gases from blast furnaces working with coal. But all these new sources have so far added only about 40,000 tons of sulphate of ammonia to our supply, making a total of 180,000 tons per annum, of which about 120,000 are produced in the United Kingdom, while we still import 650,000 tons of nitrate of soda, equivalent to 500,000 tons of sulphate of ammonia, to make up our requirements.

Many processes have from time to time been proposed to obtain ammonia from other sources. The distillation of turf, which contains upwards of 3 per cent. of nitrogen, has received much attention, and a large number of inventors have endeavoured to produce ammonia from the nitrogen of the air; but none of these processes have to my knowledge been successful on a manufacturing scale.

My attention was called to this subject at an early part of my career. Already, as far back as 1864, I undertook experiments to utilise, for the production of ammonia, waste leather, a waste material of animal origin at once abundant and very rich in nitrogen, containing from 12 per cent. to 15 per cent. of this element. Distillation in iron retorts yielded about half the nitrogen of this material in the form of ammonia, the carbon remaining in the retorts containing still from 6 per cent. to 8 per cent. Distillation with a moderate quantity of hydrate of lime increased the yield of ammonia only by 1 per cent. to 1½ per cent. A rather better result was obtained by distilling the ground residual carbon with hydrate of lime; but this operation proceeded very slowly, and the total yield of ammonia still remained very far below the quantity theoretically obtainable, so that I came to the conclusion that it was more rational to utilise the leather, reduced to powder by mechanical means, by mixing it directly with other manures.

A few years later I became connected with a large animal charcoal works, in which sulphate of ammonia was obtained as a by-product. Here again I was met with the fact that the yield of ammonia by no means corresponded with the nitrogen in the raw material, and that the charcoal remaining in the retorts contained still about half as much nitrogen as had been present in the bones used.

From this time forward my attention was for many years given exclusively to the soda manufacture, and it was only in 1879 that I again took up the question of ammonia. I then determined to submit the various processes which had

been proposed for obtaining ammonia from the nitrogen of the air to a searching investigation, and engaged Mr. Joseph Hawliczek to carry out the experimental work.

These processes may be broadly divided into three classes :

- (1.) Processes which propose to combine nascent hydrogen with nitrogen at high temperatures or by electricity, with or without the presence of acid gases.
- (2.) Processes in which nitriles are first formed, from which ammonia is obtained by the action of hydrogen or steam.
- (3.) Processes in which cyanides are first formed and the ammonia obtained from these by the action of steam.

We began with an investigation of those processes in which a mixture of steam and nitrogen or of steam and air is made to act upon coke at a high temperature, sometimes in the presence of lime, baryta, or an alkali, sometimes in the presence of hydrochloric acid.

Very numerous patents have been taken out in this direction, and there is no doubt that ammonia has been obtained by these processes by many inventors; but as I was aware that coke contains a considerable quantity of nitrogen, frequently as much as 1.5 per cent., which might be the source of the ammonia obtained, I determined to carry on the investigation in such a way as to make quite certain whether we obtained the ammonia from the coke or from the nitrogen of the atmosphere, or from both. For this purpose we made for every experiment carried on by a mixture of nitrogen or air with steam another experiment with steam alone, carefully excluding nitrogen from the apparatus. A very large number of experiments carried on at carefully determined temperatures, ranging from 500° to 1,200° C., and in which the directions given by the various inventors were most carefully observed, all led to the same result, viz., that the quantities of ammonia obtained were the same whether nitrogen was introduced into the apparatus with the steam or whether steam alone was used, thus proving conclusively that the ammonia obtained was derived from the nitrogen contained in the coke.

Further, on carefully determining the nitrogen in the coke used, it was found that the quantity of ammonia we had obtained in burning coke in a current of nitrogen and steam very nearly corresponded with the total nitrogen in the coke, so that we subsequently made our nitrogen determinations in the coke by simply burning it in a current of steam.

A process belonging to this class, proposed by Hugo Fleck, in which a mixture of carbonic oxide, steam, and nitrogen is made to pass over lime at a moderate red heat in order to obtain ammonia, was also carefully tried. It was claimed for this process that it produced nascent hydrogen at temperatures at which the ammonia is not dissociated, and for this reason succeeded where others had failed. We found that a considerable amount of hydrogen was obtained in this way at a temperature not exceeding 350° C., and that the reaction was nearly complete at 500° C.; but although we tried many experiments over a great range of temperatures, we never obtained a trace of ammonia by this process.

Amongst experiments with processes of the second class, based upon the formation of nitriles and their subsequent decomposition, the nitriles of boron and titanium had received most attention from inventors. The nitride of boron, which is obtained by treating boric acid with carbon in the presence of nitrogen, when acted upon by steam, forms boric acid again and yields the whole of its nitrogen in the form of ammonia; but the high temperature at which the first reaction takes place, and the volatility of boric acid in a current of steam, make it impossible to utilise this reaction industrially.

There seemed to be a better chance for a process patented by M. Tessier du Mothay, who proposed to bring a mixture of nitrogen and hydrogen into contact with titanium nitride and thus to form ammonia continuously. Titanium is the only element of which we know at present several combinations with nitrogen, and the higher of these does on being acted upon by a current of hydrogen at an elevated temperature, produce ammonia and a lower nitride of titanium; but this lower nitride does not absorb nitrogen under any of the conditions under which we tried it, which explains the fact that if we passed a current of hydrogen and nitrogen

over the higher nitride, we at first obtained a quantity of ammonia corresponding to the quantity which the nitride would give with hydrogen alone, but that the formation of ammonia then ceased completely.

Thus far we had quite failed to get the nitrogen of the air into action.

With the third class of processes, however, based upon the formation in the first instance of cyanides, we found by our very first experiments that the nitrogen of the atmosphere can be easily led into combination. A few experiments showed that the cyanide of barium was much more readily formed than any other cyanide; so we gave our full attention from this time to the process for obtaining ammonia by means of cyanide of barium invented by MM. Marguerite and Sourdeval. This process consists in heating a mixture of carbonate of barium with carbon in the presence of nitrogen, and subsequently treating the cyanide of barium produced with steam, thus producing ammonia and regenerating the carbonate of barium. A great difficulty in this process is that the carbonate of barium fuses at high temperatures, and when fused attacks fireclay goods very powerfully.

We found that this can be overcome by mixing the carbonate of barium with a sufficient quantity of carbon and a small quantity of pitch, and that in this way balls can be made which will not fuse, so that they can be treated in a continuous apparatus in which the broken briquettes can be charged from the top, and after treatment can be withdrawn from the bottom.

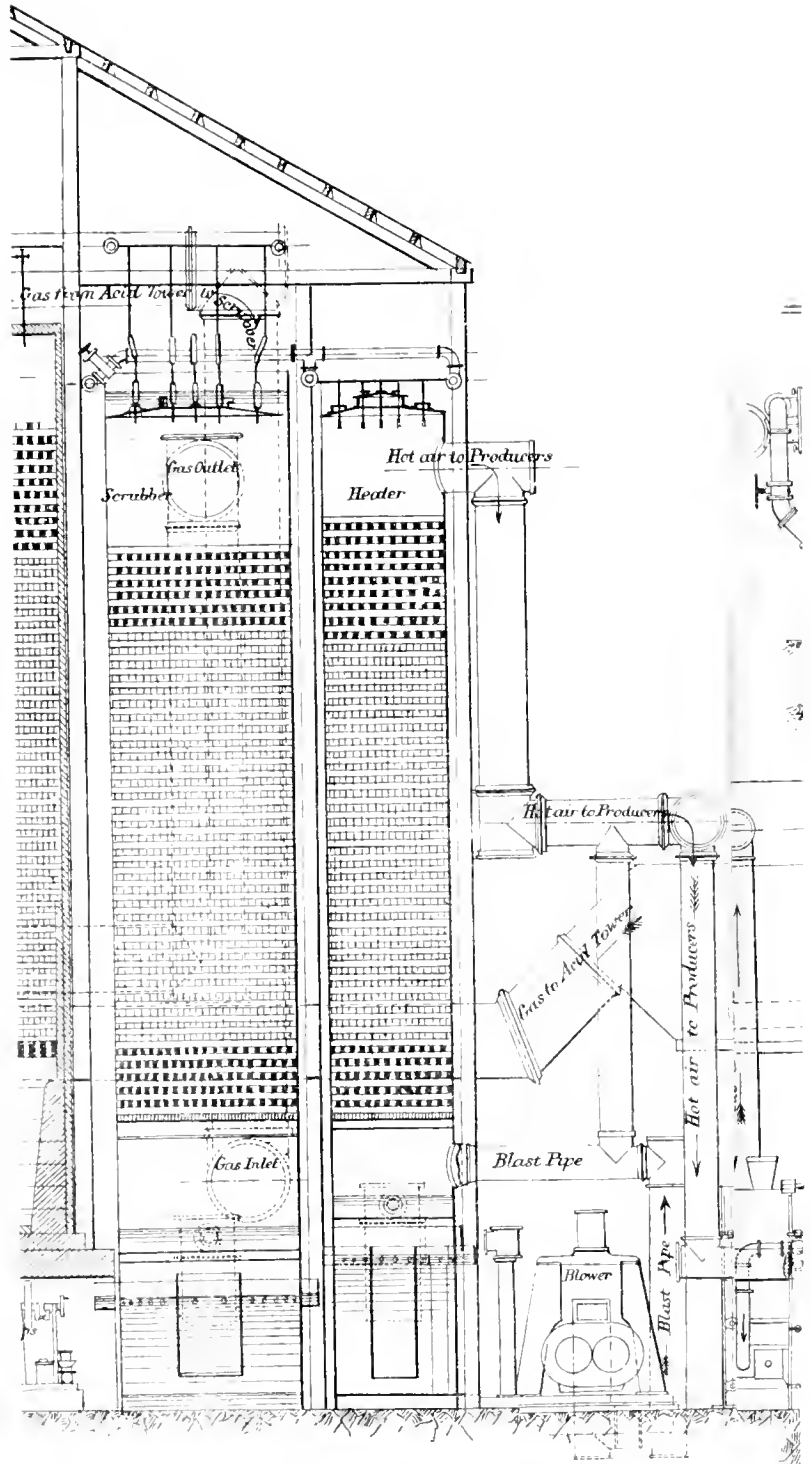

We found that the formation of cyanides required a temperature of at least 1,200° C., and proceeded most readily at 1,400° C., temperatures which, although difficult to attain, are still quite within the range of practical working; and we found no difficulty in obtaining a product containing 30 per cent. of barium cyanide, corresponding to a conversion into cyanide of 40 per cent. of the barium present.

We found, however, that the cyanide when exposed to the atmosphere at a temperature above 300° C. is readily destroyed under re-formation of carbonate of barium, so that it is absolutely necessary to cool it down to this temperature before exposing it to the atmosphere, a fact of great importance that had hitherto been overlooked.

The operation for producing ammonia and regenerating the carbonate of barium by acting upon the cyanide with steam offers no difficulty whatever, and if the temperature is not allowed to exceed 500° C. the results are quantitative. The regenerated carbonate of barium acts actually better than the ground witherite used in the first instance, and if care is taken that no impurities are introduced by the pitch which is used to re-make the briquettes and to replace the small amount of carbon consumed at each operation, I see no reason why it should not continue to act for a very long time.

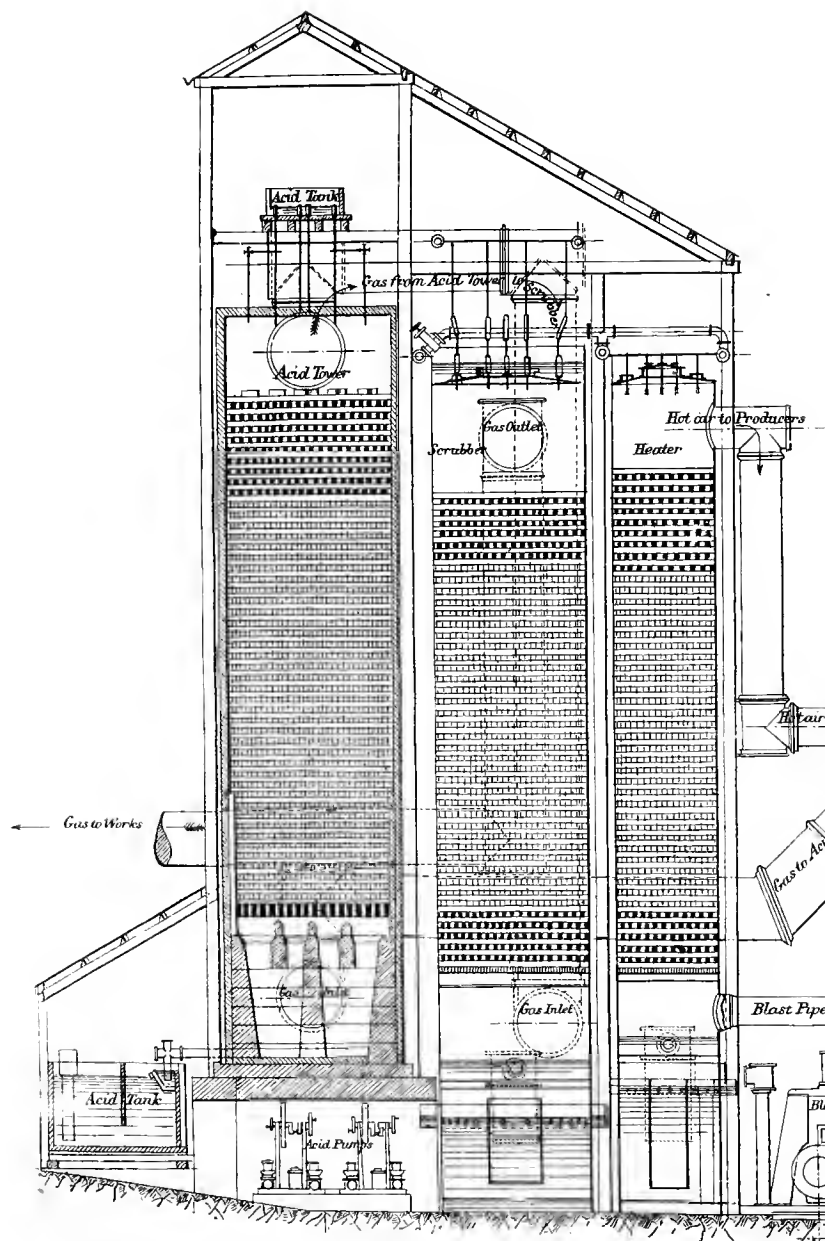

The cyanide is not acted on by carbonic oxide, but carbonic acid destroys it at high temperatures, so that it is not possible to produce it by heating the briquettes directly in a flame free from oxygen, but containing carbonic acid. The process has, therefore, to be carried out in closed vessels, and I designed for this purpose the following apparatus:—

Clay retorts of moderate dimensions and thin walls are placed vertically in a furnace, passing through the hearth as well as through the arch of the furnace. These are joined at the bottom to cast-iron retorts of the same shape as the earthenware retort. Through a cast-iron mouthpiece on the top of the retort the material was introduced, while in the cast-iron retort below, the material was cooled to the necessary temperature by radiation, and by the cold nitrogen gas introduced into the bottom of it. The lower end of the cast-iron retort was furnished with an arrangement for taking out from time to time small quantities of the material, while fresh material was in the same proportion fed in at the top. As a source of nitrogen I used the gases escaping from the carbonating towers of the ammonia-soda process. The formation of cyanide of barium from barium carbonate, carbon and nitrogen absorbs a very large amount of heat—no less than 97,000 calories per equivalent of the cyanide formed—which heat has to be transmitted

Cross Section through Gas Producers.

Longitudinal Section of Plant obtaining Ammonia from Gas Producers.

through the walls of the retort. I therefore considered it necessary to use retorts with very thin walls, but I did not succeed in obtaining retorts of this description which would resist the very high temperatures which the process requires, and for this reason I abandoned these experiments. I was at that time not acquainted with the excellent quality of clay retorts used in zinc works, with which I have since experimented for a different purpose. I have no doubt that with such retorts the production of cyanides by this process can be carried out without great difficulty.

I believe that the process will prove remunerative for the manufacture of cyanogen products, which, if produced more cheaply, may in the future play an important rôle in organic synthesis, in the extraction of noble metals and possibly other chemical and metallurgical operations.

The process certainly also offers a solution of the problem of obtaining ammonia from the nitrogen of the atmosphere, but whether this can be done with satisfactory commercial results is a question I cannot at present answer, as I have not been able to secure the data for making the necessary calculations.

I am the more doubtful about this point, as in the course of our investigations I have found means to produce ammonia at small cost and in great abundance from the immense store of combined nitrogen which we possess in our coal-fields.

Among the processes for obtaining ammonia from the nitrogen of the air which we investigated, was one apparently of great simplicity, patented by Messrs. Rickman and Thompson. These gentlemen state that by passing air and steam through a deep-coal fire, the nitrogen so passed through is to a certain extent converted into ammonia. In investigating this statement we found that the process described certainly yields a considerable quantity of ammonia, but when we burned the same coal at a moderate temperature by means of steam alone in a tube heated from the outside, we obtained twice as much ammonia as we had done by burning it with a mixture of air and steam, proving in this case, as in all others, the source of the ammonia to have been the nitrogen contained in the coal. The quantity of ammonia obtained was, however, so large that I determined to follow up this experience, and at once commenced experiments on a semi-manufacturing scale to ascertain whether they would lead to practical and economic results.

I came to the conclusion that burning coal by steam alone at temperatures at which the ammonia formed should not be dissociated, although it yielded more ammonia, would not lead to an economic process, because it would require apparatus heated from the outside, of great complication, bulk, and costliness, on account of the immense quantity of raw material to be treated for a small amount of ammonia obtainable.

On the other hand, if the coal could be burned in gas producers by a mixture of air and steam, the plant and working of it would be simple and inexpensive, the gas obtained could be utilised in the same way as ordinary producer gas, and would pay to a large extent for the coal used in the operation, so that although only one-half of the ammonia would be obtained, it seemed probable that the result would be economical.

I consequently constructed gas producers and absorbing plant of various designs and carried on experiments for a number of years. These experiments were superintended by Mr. G. H. Beckett, Dr. Carl Markel, and, during the last four years, by Dr. Adolf Staub, to whose zeal and energy I am much indebted for the success that has been achieved. The object of these experiments was to determine the most favourable conditions for the economic working of the process with respect to both the cost of manufacture as well as the first cost and simplicity of plant. The cost of manufacture depends mainly upon the yield of ammonia, as the expenses remain almost the same whether a large or a small amount of ammonia is obtained; the only other item of importance is the quantity of steam used in the process. We found the yield of ammonia to vary with the temperature at which the producer was working, and to be highest when the producer was worked as cool as was compatible with a good combustion of the fuel. The temperature again depended upon the amount of steam introduced into the

producer, and of course decreased the more the steam increased. We obtained the best practical results by introducing about two tons of steam for every ton of fuel consumed. We experimented upon numerous kinds of fuel, common slack and burgy of the Lancashire, Staffordshire, and Nottinghamshire districts. We found not much difference in the amount of nitrogen contained in these fuels, which varied between 1.2 and 1.6 per cent., nor did we find much difference in the ammonia obtained from these fuels if worked under similar conditions. Employing the quantity of steam just named we recovered about half the nitrogen in the form of ammonia, yielding on an average 0.8 per cent. of ammonia, equal to 32 kilos. of sulphate per ton of fuel. In order to obtain regular results we found it necessary to work with a great depth of fuel in the producers, so that slight irregularities in the working would not affect results. Open burning kinds of slack do of course work with the greater ease, but there is no difficulty in using a caking fuel, as the low temperature at which the producers work prevents clinkering and diminishes the tendency of such fuels to cake together.

The quantity of steam thus required to obtain a good yield of ammonia is rather considerable, and threatened to become a serious item of expense. Only one-third of this steam is decomposed in its passage through the producer, and two-thirds remain mixed with the gases which leave the producer. My endeavours were consequently directed towards finding means to recover this steam, and to return it to the producers, and also to utilise the heat of the gases which leave the producers with a temperature of 450° to 500° C., for raising steam for the same purpose. The difficulties in the way of attaining this end and at the same time of recovering, in a simple manner, the small amount of ammonia contained in the immense volume of gas we have to deal with, were very great. We obtain from one ton of coal 160,000 cubic feet of dry gas at 0° C. and atmospheric pressure. The steam mixed with this gas as it leaves the producer adds another 80,000 cubic feet to this, and the large amount of latent heat in this quantity of steam makes the problem still more difficult. The application of cooling arrangements, such as have been successfully applied to blast-furnace gases, in which there is no steam present, and which depend upon the cooling through the metallic sides of the apparatus, is here practically out of the question. After trying a number of different kinds of apparatus, I have succeeded in solving the problem in the following way:—

The gases issuing from the producers are led through a rectangular chamber partly filled with water, which is thrown up in a fine spray by revolving beaters so as to fill the whole area of the chamber. This water, of course, becomes hot; a certain quantity of it evaporates, the spray produced washes all dust and soot out of the gases, and also condenses the fixed ammonia. The water thus becomes, to a certain degree, saturated with ammonia salts, and a certain portion of it is regularly removed from the chamber and distilled with lime to recover the ammonia. This chamber is provided with water lutes, through which the tar condensed in it is from time to time removed. From this chamber the gases, which are now cooled down to about 100° C., and are loaded with a large amount of water-vapour, are passed through a scrubber filled with perforated bricks, in which the ammonia contained in the gases is absorbed by sulphuric acid. In this scrubber a fairly concentrated solution of sulphate of ammonia containing 36 to 38 per cent. is used, to which a small quantity of sulphuric acid is added, so that the liquid leaving the scrubber contains only 2.5 per cent. of free acid. This is necessary, as a liquid containing more acid would act upon the tarry matter and produce a very dark-coloured solution. The liquid running from the scrubber is passed through a separator in which the solution of sulphate of ammonia separates from the tar. The greater portion of the clear liquid is, after adding a fresh quantity of acid to it, pumped back through the scrubber. A certain portion of it is, after treatment with a small quantity of heavy tar-oils, which take the tarry matter dissolved in it out, evaporated in conical lead-lined pans furnished with lead steam coils, and which are kept constantly filled by the addition of fresh liquor until the whole mass is thick. This is then run out on a strainer

and yields, after draining and washing with a little water, a sulphate of ammonia of very fair quality, which finds a ready sale. The mother-liquor, which contains all the free acid, is pumped back to the scrubber. The gas on entering this scrubber contains only 0.13 volume per cent. of ammonia, and on leaving the scrubber it contains not more than one-tenth of this quantity. Its temperature has been reduced to 80° C., and is fully saturated with moisture, so that practically no condensation of water takes place in the scrubber. The gas is next passed through a second scrubber filled with perforated wood blocks. In this it meets with a current of cold water which condenses the steam, the water being thereby heated to about 78° C. In this scrubber the gas is cooled down to about 40°–50° C., and passes from it to the gas main leading to the various places where it is to be consumed. The hot water obtained in this second scrubber is passed through a vessel suitably constructed for separating the tar which is mixed with it, and is then pumped through a third scrubber, through which, in an opposite direction to the hot water, cold air is passed. This is forced by means of a Roots blower through the scrubber into the producer. The air gets heated to about 76° C. and saturated with moisture at that temperature by its contact with the hot water, and the water leaves this third scrubber cold enough to be pumped back through the second scrubber. The same quantity of water is thus constantly used for condensing the water-vapour in one scrubber and giving it up to the air in the other. In this way we recover and return to the producer fully two-thirds of the steam which has been originally introduced, so that we have to add to the air, which has thus been loaded with moisture, an additional quantity of steam equal to only one-third of the total quantity required before it enters the producer. This additional quantity of steam, which amounts to 0.6 ton of steam for every ton of fuel burnt, we obtain as exhaust steam from the engines driving the blowers and pumps required for working the plant.

The gas producers which I prefer to use are of rectangular shape, so that a number of them can be put into a row. They are 6 feet wide and 12 feet long inside. The air is introduced and the ashes removed at the two small sides of the producer which taper towards the middle and are closed at the bottom by a water-lute of sufficient depth for the pressure under which the air is forced in, equal to about 4 inches of water. The ashes are taken out from underneath the water, the producers having no grate or fire-bars at all. The air enters just above the level of the water through a pipe connected with the blower. These small sides of the producer rest upon cast-iron plates lined to a certain height with brickwork, and this brickwork is carried by horizontal cast-iron plates above the air entrance. In this way a chamber is formed of triangular shape, one side of which is closed by the ashes, and thus the air is distributed over the whole width of the producer.

The gas is taken out in the middle of the top of the producer by an iron pipe and fuel charged in by hoppers on both sides of this pipe. Between the pipe and the hoppers two hanging arches are put into the producers a certain distance down and the fuel is kept above the bottom level of these hanging arches. This compels the products of distillation, produced when fresh fuel is charged in, to pass through the incandescent fuel between the two hanging arches, whereby the tarry products are to a considerable extent converted into permanent gas, and the coal dust arising from the charging is kept back in the producer.

The details of construction of this plant will be easily understood by reference to the diagrams before you.

The fuel we use is a common kind of slack, and contains, on an average, 33.5 per cent. of volatile matter, including water, and 11.5 per cent. of ashes, leaving 55 per cent. of non-volatile carbon.

The cinders which we take out of the producer contain, on an average, 33 per cent. of carbon. Of this we recover about one-half by riddling or picking, which we return to the producer. The amount of unburnt carbon lost in the cinders is thus not more than 3 per cent. to 4 per cent. on the weight of fuel used.

The gas we obtain contains, in a dry state, on an average, 15 per cent. of carbonic acid, 10 per cent. of carbonic oxide, 23 per cent. of hydrogen, 3 per cent. of hydrocarbons, and 49 per cent. of nitrogen.

The calorific value of this gas is very nearly equal to 73 per cent. of the calorific value of the fuel used, but in using this gas for heating purposes, such as raising steam or making salt, we utilise the heat it can give very much better than in burning fuel, as we can completely burn it with almost the theoretical quantity of air, so that the products of combustion resulting do not contain more than 1 to 2 per cent. of free oxygen. Consequently the heat escaping into the chimney is very much less than when fuel is burnt direct, and we arrive at evaporating, by means of the gas, 85 per cent. of the water that we would evaporate by burning the fuel direct, in ordinary fire-places.

We have, however, to use a certain quantity of steam in the producers, and in evaporating the sulphate of ammonia liquors, which has to be deducted from the steam that can be raised by the gas in order to get at the quantity of available steam therefrom obtainable. The former amounts, as already stated, to 0.6 ton, the latter to 0.1 ton of steam per ton of fuel burnt, making a total of 0.7 ton. The gas obtained from one ton of fuel evaporates 5.8 tons of water in good steam boilers, working at a rate of evaporation of 50 to 55 tons per 24 hours under 90 lbs. pressure. Deducting from this the 0.7 ton necessary for working the plant, leaves an available amount of steam raised by the gas from one ton of fuel of 5.1 tons, equal to 75 per cent. of the steam that we can obtain from the same fuel by hand-firing.

In addition to the gas, we obtain about 3 per cent. of tar from the fuel. This tar is very thick, and of little commercial value. It contains only 4 per cent. of oils volatile below 200° C., and 38 per cent. of oils of a higher boiling point, consisting mostly of creosote oils very similar to those obtained from blast furnaces; and only small quantities of anthracene and paraffin wax.

I have made no attempts to utilise this tar except as fuel. It evaporates nearly twice as much water as its weight of coal, and we have thus to add its evaporative efficiency to that of the gas given above, leading to a total of about 80 per cent. of the evaporative efficiency of the fuel used in the producers. The loss involved in gasifying the fuel to recover the ammonia therefrom amounts thus to 20 per cent. of the fuel used. This means that, where we have now to burn 100 tons of fuel, we shall have to burn 125 tons in the producers in order to obtain ammonia equal to about half the nitrogen contained therein. Our actual yield of ammonia on a large scale amounting on an average to 32 kilos., equal to 70.6 lb. per ton of fuel, 125 tons of fuel will turn out 4 tons of sulphate of ammonia. We thus consume 6.25 tons of fuel for every ton of sulphate obtained, or nearly the same quantity as is used in producing a ton of caustic soda by the Le Blanc process—a product not more than half the value of ammonium sulphate. At present prices in Northwich this fuel represents a value of 35s. If we add to this the extra cost of labour over and above the cost of burning fuel in ordinary fire-places, the cost of sulphuric acid, bags, &c., we come to a total of 4*l.* 10*s.* to 5*l.* per ton of sulphate of ammonia, which at the present selling price of this article, say 12*l.* per ton, leaves, after a liberal allowance for wear and tear of plant, an ample margin of profit. With a rise in the price of fuel, this margin, however, rapidly decreases, and the working of the process will, of course, be much more expensive on a small scale, as will also be the cost of the plant, which under all circumstances is very considerable. The great advantages incidental to this process over and above the profit arising from the manufacture of sulphate of ammonia, viz., the absolute impossibility of producing smoke and the great regularity of the heating resulting from the use of gas, are therefore, as far as I can see for the present, only available for large consumers of cheap fuel.

We have tried many experiments to produce hydrochloric acid in the producers, with the hope of thereby increasing the yield of ammonia, as it is well known that ammonium chloride vapour, although it consists of a mixture of ammonia gas and hydrochloric acid gas, is not at all dissociated at temperatures at which the dissociation of ammonia alone has already taken place to a considerable extent.

I had also hoped that I might in this way produce the acid necessary to combine with the ammonia at very small cost. For this purpose we moistened the fuel used with concentrated brine, and also with the waste liquors from the ammonia-soda manufacture, consisting mainly of chloride of calcium; and we also introduced with the fuel balls made by mixing very concentrated chloride of calcium solution with clay, which allowed us to produce a larger quantity of hydrochloric acid in the producer than by the other methods. We did in this way succeed in producing hydrochloric acid sometimes less and sometimes more than was necessary to combine with the ammonia, but we did not succeed in producing with regularity the exact amount of acid necessary to neutralise the ammonia. When the ammonia was in excess we had therefore to use sulphuric acid as before to absorb this excess, and we were never certain that sometimes the hydrochloric acid might not be in excess, which would have necessitated to construct the whole plant so that it could have resisted the action of weak hydrochloric acid—a difficulty which I have not ventured to attack. The yield of ammonia was not in any case increased by the presence of the hydrochloric acid. This explains itself if we consider that there is only a very small amount of ammonia and hydrochloric acid diffused through a very large volume of other gases, so that the very peculiar protective action which the hydrochloric acid does exercise in retarding the dissociation of ammonia in ammonium chloride vapour, where an atom of ammonia is always in contact with an atom of hydrochloric acid, will be diminished almost to zero in such a dilute gas where the atoms of hydrochloric acid and ammonia will only rarely come into immediate contact with each other. When we burnt coke by a mixture of air and steam in presence of a large excess of hydrochloric acid, the yield of ammonia certainly was thereby considerably increased, but such a large excess cannot be used on an industrial scale. I have therefore for the present to rest satisfied with obtaining only half the nitrogen contained in the fuel in the form of ammonia.

The enormous consumption of fuel in this country—amounting to no less than 150 million tons per annum—would at this rate yield as much as five million tons of sulphate of ammonia a year, so that if only one-tenth of this fuel would be treated by the process, England alone could supply the whole of the nitrogenous compounds, sulphate of ammonia, and nitrate of soda at present consumed by the Old World. As the process is especially profitable for large consumers of fuel situated in districts where fuel is cheap, it seems to me particularly suitable to be adopted in this country. It promises to give England the privilege of supplying the Old World with this all-important fertiliser, and while yielding a fair profit to the invested capital and finding employment for a considerable number of men, to make us, last not least, independent of the New World for our supply of so indispensable a commodity.

Before leaving my subject, I will, if you will allow me, give you in a few words a description of two other inventions which have been the outcome of this research. While looking one day at the beautiful, almost colourless, flame of the producer gas burning under one of our boilers, it occurred to me that a gas so rich in hydrogen might be turned to better use, and that it might be possible to convert it direct into electricity by means of a gas battery.

You all know that Lord Justice Grove showed, now 50 years ago, that two strips of platinum partly immersed in dilute sulphuric acid, one of which is in contact with hydrogen and the other with oxygen, produce electricity. I will not detain you with the many and varied forms of gas batteries which Dr. Carl Langer (to whom I entrusted this investigation) has made and tried during the last four years, in order to arrive at the construction of a gas battery which would give a practical result, but I will call your attention to the battery before me on the table, which is the last result of our extended labours in this direction, and which we hope will mark a great step in advance in the economic production of electricity.

The distinguishing feature of this battery is that the electrolyte is not employed as a mobile liquid, but in a

quasi-solid form, and it is, therefore, named Dry-gas battery. It consists of a number of elements, which are formed of a porous diaphragm of a non-conducting material (in this instance plaster of Paris), which is impregnated with dilute sulphuric acid. Both sides of this diaphragm are covered with very fine platinum leaf perforated with very numerous small holes, and over this a thin film of platinum black. Both these coatings are in contact with frameworks of lead and antimony, insulated one from the other, which conduct the electricity to the poles of the battery.

A number of these elements are placed side by side, with non-conducting frames intervening, so as to form chambers through which the hydrogen gas is passed along one side of the element and air along the other.

This peculiar construction allows us to get a very large amount of duty from a very small amount of platinum. One of the batteries before you, consisting of seven elements, with a total effective surface of half a square metre, contains 2½ grms. of platinum leaf and 7 grms. of platinum black, a total of 9½ grms. of platinum, and produces a current of 2 amperes and 5 volts, or 10 watt, when the outer resistance is properly adjusted. This current is equal to nearly 50 per cent. of the total energy obtainable from the hydrogen absorbed in the battery.

In order to maintain a constant current, we have from time to time (say once an hour) to interchange the gases, so as to counteract the disturbing influence produced by the transport of the sulphuric acid from one side of the diaphragm to the other. This operation can easily be performed automatically by a commutator worked by a clock.

The water produced in the battery by the oxidation of the hydrogen is carried off by the inert gas mixed with the hydrogen, and by the air of which we use a certain excess for this purpose. This is important, as if the platinum black becomes wet, it loses its absorbing power for the gases almost completely and stops the work of the battery. To avoid this was in fact the great difficulty in designing a powerful gas battery, and all previous constructions which employed the electrolyte as a mobile liquid failed in consequence.

The results obtained by our battery are practically the same whether pure oxygen and hydrogen or air and gases containing 25 per cent. of hydrogen are used; but we found that the latter gases must be practically free from carbonic oxide and hydrocarbons, which both interfere very much with the absorbing power of the platinum black. We had thus to find a cheap method of eliminating these two gases from the producer gas, and converting them at the same time into their equivalent of hydrogen. The processes hitherto known for this purpose, viz., passing a mixture of such gases with steam over lime (which I mentioned some time ago) or over oxide of iron or manganese, require high temperatures which render them expensive, and the latter do not effect the reaction to a sufficient extent for our purpose.

We have succeeded in attaining our object at a temperature below that at which the gases leave my producers, viz., at 350° C. to 450° C., by passing the producer gases, still containing a considerable excess of steam, over metallic nickel or cobalt. These metals have the extraordinary property of decomposing almost completely, even at the low temperature named, carbonic oxide into carbon and carbonic acid and hydrocarbons into carbon and hydrogen.

In order to carry the process out with small quantities of nickel and cobalt, we impregnate pumice stone or similar material with a salt of nickel or cobalt, and reduce this by means of hydrogen or producer gas. These pieces of pumice stone are filled into a retort or chamber and the hot gases passed through them. As the reaction produces heat it is not necessary to heat the chambers or retorts from the outside when the necessary temperature has once been attained. This process has not yet been carried out on a large scale, but the laboratory experiments have been so satisfactory that we have no doubt as to its complete success. It will enable us to obtain gases containing 36 per cent. to 40 per cent. of hydrogen and practically free from carbonic oxide and hydrocarbons from producer gas at a very small cost, and thus to make the latter suitable for the production of electricity by our gas battery. We obtain, as stated before

50 per cent. of the energy in the hydrogen absorbed in the battery in the form of electricity, while, if the same gas was consumed under steam boilers to make steam, which, as I have shown before, could in this way be raised cheaper than by burning fuel direct, and if this steam was turned into motive-power by first-rate steam engines, and the motive power converted into electricity by a dynamo, the yield of electricity would in the most favourable case not exceed 8 per cent. of the energy in the gas. I hope that this kind of battery will one day enable us to perform chemical operations by electricity on the largest scale, and to press this potent power into the service of the chemical industries.

The statement is frequently made that "Necessity is the mother of invention." If this has been the case in the past I think it is no longer so in our days, since science has made us acquainted with the correlation of forces, teaching us what amount of energy we utilise and how much we waste in our various methods for attaining certain objects, and indicating to us where and in what direction and how far improvement is possible; and since the increase in our knowledge of the properties of matter enables us to form an opinion beforehand as to the substances we have available for obtaining a desired result. We can now foresee, in most cases, in what direction progress in technology will move, and, in consequence, the inventor is now frequently in advance of the wants of his time. He may even create new wants, to my mind a distinct step in the development of human culture. It can then no longer be stated that "Necessity is the mother of invention;" but I think it may truly be said that the steady methodical investigation of natural phenomena is the father of industrial progress.

SIR LOWTHIAN BELL, Bart., F.R.S., in moving a vote of thanks, said that the meeting had had the privilege of listening to a description of results obtained by a man of exceptional intelligence and learning supplemented by that devotion of mind which qualified him to pursue his work with great energy and perseverance. The importance of the President's address could not possibly be over-rated. At various periods different substances had been put forward as indications of the civilisation of the people. He remembered hearing from Dr. Ure that he considered the consumption of sulphuric acid to be the most accurate measure of the civilisation of a people. In course of time sulphuric acid gave way to soap, the consumption of which was probably still regarded as the great exponent of civilisation by such of his fellow-citizens as had thereby made their name. From what he had heard that morning, however, he should be inclined to make soap yield to ammonia, as sulphuric acid had in its time succumbed to soap. For not only was ammonia of great importance to us as a manufacturing nation, but it almost appeared to be a condition of our existence. England had a large population concentrated on an area so small as to make it almost a matter of apprehension whether the surface could maintain the people upon it. We were now importing almost as much food as we consumed, and were thus more and more dependent on the foreigner. Under certain conditions this would become a very serious matter, and thus any one who showed how to produce plenty of ammonia at a cheap rate was a benefactor to his country. Mr. Mond's process seemed to come nearer to success than any which had preceded it, and it needed no words from him to induce the meeting to accord a hearty vote of thanks to the President for his admirable paper.

MR. J. C. STEVENSON, M.P., in seconding the motion, said that no paper could be more interesting and valuable to the Society than that just delivered by the President. It opened out a future for the advancement of chemical industry, which almost overcame one by the greatness of its possibilities. Mr. Mond had performed an invaluable service by investigating the various methods proposed for the manufacture of ammonia, and clearing the decks of those processes supposed by their inventors to be valuable but proved by him to be delusive. It gave him hearty pleasure therefore to second the vote of thanks proposed by Sir Lowthian Bell.

The vote having been put and carried by acclamation, after a brief reply from the President:

The SECRETARY read the report of the scrutators, which showed that 158 ballot papers had been sent in, 154 voting for the proposed list intact, and four substituting other names. The gentlemen nominated in the list issued by the Council were therefore declared elected.

The following is a list of the Council for 1889—90.

President.

Sir Lowthian Bell, Bart., F.R.S.

Vice-Presidents.

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Müller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schunck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

Members of Council.

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Brook.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

Treasurer.

E. Rider Cook.

Foreign Secretary.

Dr. Ferdinand Huerter.

The PRESIDENT moved a vote of thanks to the managers of the Royal Institution for their kindness in permitting the Society to meet in that renowned and historic place, and which he hoped would be a good augury for the success of the business still before them. In proposing this vote, he wished particularly to express thanks to his friend, Professor Dewar, to whom the Society was indebted for the invitation.

DR. W. H. PERKIN, F.R.S., seconded the resolution, which was carried by acclamation.

The PRESIDENT then proposed a vote of thanks to the officers of the Society, the officers of Sections, and the Editor and staff of the Journal. It was, he said, quite unnecessary for him to speak to members of the Society of the merits of those gentlemen. Month by month the results of their labours came before the members, who, he hoped, made it their duty to go carefully through the Journal and make those results their own.

MR. DAVID HOWARD had great pleasure in seconding the proposal. He had watched very carefully the working of the Society during the past year, and was, therefore, in a position to know how much it owed to its officers. The effective power of a great machine was in proportion to the absence of friction, and, happily for the Society of Chemical Industry, there had been so little friction in its working that there was but little palpable evidence of the force exerted. That force was exerted in the right direction, and the success of the Society must be the measure of the skill of its officers, and not the noise made in the process.

This concluded the business of the meeting, but before separating, advantage was taken of the opportunity afforded for inspecting the laboratories, physical and chemical, and the historic collection of apparatus belonging to the Institution, under the guidance of Professor Dewar's assistants, Mr. R. N. Lennox and Mr. J. W. Heath.

VISIT TO MESSRS. DOULTON'S LAMBETH POTTERY.

About 230 members then made their way to Messrs. Doulton's art pottery on the Albert embankment, and, by invitation of Sir Henry Doulton, partook of luncheon. This was served in the dining rooms ordinarily set apart for the use of the artists. Ranged along the walls were cases

containing historical collections of the Lambeth Pottery Japan productions, with a small but choice selection of Japanese, French, Italian, and other foreign specimens of ceramic ware.

Meanwhile a select company was entertained by Sir Henry Doulton in his own room. In reply to a vote of thanks proposed by the President, Mr. Ludwig Mond, and received with enthusiasm, Sir Henry Doulton made some interesting statements with regard to his staff of artists and designers, and the educational course by means of which the firm obtained their supply of artistic talent. He said, that whatever might be alleged as to the need of imported talent from abroad for other purposes, he had found no such necessity in his department. His supplies of artists and designers came from the locality, and he had never regretted the day when he succeeded in securing the co-operation of the Lambeth School of Art. He had found to his surprise plenty of artistic talent in Lambeth, and he believed that the nation generally only needed development by a proper system of education to afford artists and designers in abundance. He thought that every child should learn drawing in order to secure that concert of hand and eye which was the basis of all art-work; but beyond this there still remained a rarer and higher gift, viz., that imaginative and creative faculty known as genius, which differed as much from educated mediocrity as did the well-spring from the pool. That too—as they would see for themselves—was to be had in Lambeth.

From the luncheon rooms parties of members, conducted by Sir Henry Doulton, Messrs. H. L. and J. Doulton, Mr. W. P. Rix, and the managers of departments, started at short intervals to inspect the processes carried on in the studios and works. Only a comparatively small portion of the premises were seen on this occasion; time would not permit more than a tithe of the somewhat scattered series of buildings that constitute the Lambeth pottery to be seen. The works cover some seven or eight acres of ground, and over 1,600 persons are now employed. Commencing on the ground floor with the department devoted to the rapid and almost automatic production by machinery of the humble but useful drain pipes, which are still the staple production of the firm, the visitors viewed with interest the process of "throwing" and "lathing," the building up of large chemical vessels and condensing worms, the fitting together of stoneware taps, and machine presses for the production of chemical pipes and bends. Huge flagons, bottles of all sizes, and delicate vases were seen to be formed at the various "wheels" from the same raw material and with the same rapidity and precision. From this it was but a step to the clean and well-lighted studios where the art pottery is decorated. Here the novel methods—many of them quite distinctive and peculiar to the Doulton pottery—excited much comment and admiration. The studios each contain from 10 to 30 intelligent young girls under the superintendence of a skilled forewoman. Next were reached the special rooms of those artists who have by their genius contributed so largely to the success of the firm they serve. The Misses Hannah and Florence Barlow were found etching direct on the soft clay examples of animal, bird, and plant life, Miss Hannah Barlow giving a proof of her wide knowledge of the brute creation by making some spirited impromptu etchings on a vase taken up at random. Mr. John Eyre and Mr. McLennan (painters) entertained their visitors with some fine studies of tile and panel decoration, and imparted much valuable information on the principles of art as applied to their particular industry. Mr. Marshall and Mr. Butler (designers and carvers), Miss Florence Lewis, Miss Kate Rogers, and Miss Butterson (painters of faience), and others whose names are familiar in the artistic world, were also visited; but the culminating event was a chat with Mr. George Tinworth, and an inspection of the two historical works now being modelled by him.

After viewing the studios there were the show-rooms to visit, where in addition to the large display of art-wares, a few chemical exhibits had been arranged, comprising an improved stoneware acid force-pump of six inches bore, large acid proof-cocks of the same dimensions, worms and acid pipes in stoneware, and an enormous receiver of the

same material in one piece. Here also were arranged beautiful examples of "faience," "impasto," "Silicon," and, latest production of all, "Carrara" ware. But even here the *pièce de résistance* was Mr. Tinworth's great work in clay, "Christ brought before Herod," which elicited general admiration.

VISIT TO LAMBETH PALACE.

Meanwhile, members were assembling at the gate of Lambeth Palace, the town residence of the Archbishop of Canterbury, where they were received by Mr. Mandeville B. Phillips, his Grace's private secretary. From the Gate Tower, a huge building erected by Cardinal Morton in the reign of Henry VII., visitors were conducted to the Lollards' Tower, one of the oldest parts of the building, in an upper chamber of which Sir John Oldcastle is believed to have been imprisoned. The plank walls were covered with devout inscriptions, and still showed the rings to which prisoners were chained. In the corner was the "oubliette," now closed, which tradition states to have been the mode of egress for the bodies of many victims of religious persecution. In early days this tower was nearly surrounded by water, and it is quite possible that the cellars at the base were open to the tide. At any rate, during the Commonwealth it was from this tower that the Rev. Guy Carlton let himself down by a rope, while his wife waited below in a boat. The rope proving too short, the priest had to drop, and in so doing he broke his leg. But he managed, nevertheless, to scramble into the boat, and escape to the Continent. On the Restoration he was rewarded for his devotion and pluck with a bishopric.

From the top of the Lollards' Tower is obtained a splendid view of London and the river, with the gardens and park of the palace in the foreground. In this park thousands of poor children come to play; and the boon to the poor and crowded neighbourhood which it affords is almost incalculable.

In the chapel, an early English structure, restored and embellished early in this century, the Rev. St. Clair Donaldson, one of the Archbishop's chaplains, explained that the windows, which were somewhat archaic in character, were the third set in succession made from the same design, the two previous ones having been destroyed in popular commotions. All three sets were practically alike, and were derived from a series of prints in a "block book" now preserved in the British Museum. The remains of Archbishop Parker, after enduring many vicissitudes, at length have found a resting-place here. In an adjoining room, now used as a vestry, Cranmer composed much of the English Church Service.

Passing through the dining-room, a noble apartment, on the walls of which were a chronological series of portraits of the Archbishops of Canterbury, beginning with Cranmer and Laud, and ending with Tait, the party reached the library, where, under the guidance of the librarian, Mr. S. M. Kershaw, F.S.A., they could inspect at their leisure the fine prints and works on its tables and shelves. This library was erected on the site of the old hall, pulled down during the Commonwealth, by Archbishop Juxon, who is supposed to have had some assistance from Wren. It is a curious compound of Classic and Gothic work, and has a fine oak roof.

CONVERSAZIONE.

At 9 o'clock the President and Mrs. Mond held a reception at the Grosvenor Gallery, which was attended by about 900 ladies and gentlemen. Invitations had been issued to all members of the Society of Chemical Industry, the Fellows of the Chemical Society and the Institute of Chemistry residing in or near the metropolis, and to the Councils of the Royal Society, the Royal Institution, the Institution of Civil Engineers, the Pharmaceutical Society, and other learned bodies. Among those present were:—Dr. W. J. Russell, F.R.S., President of the Chemical Society, and Miss Russell, Sir Lowthian Bell, Bart., F.R.S., and party, Mr. J. C. Stevenson, M.P., Mrs. Stevenson, and party, Professor A. R. and Mrs. Leeds, Dr. P. F. and Mrs. Frankland, Dr. J. H. Gladstone, F.R.S., and Miss Gladstone, Mr. and

Mrs. E. K. Muspratt, Mr. C. Spagnoletti, Professor W. Grylls Adams, F.R.S., Dr. and Mrs. Karl Blind, Mr. and Miss Mansergh, Dr. John Evans, F.R.S., and party, Mr. Kenrick B. Murray, Mr. Charles Cochrane, President of the Institution of Mechanical Engineers, Dr. H. Sprengel, F.R.S., Dr. Hugo Müller, F.R.S., Sir Julian Danvers, Maj.-Gen. J. F. D. Donnelly, Sir John Coode, G.C.M.G., President of the Institution of Civil Engineers, Professor S. B. Newbury, Professor W. A. Tilden, F.R.S., Professor W. Dittmar, F.R.S., Professor Dewar, F.R.S., and Mrs. Dewar, Dr. James Bell, C.B., F.R.S., President of the Institute of Chemistry, Professor Ferguson, Glasgow University, M. F. H. Gossage, Dr. P. R. Japp, F.R.S., Mr. W. Lant Carpenter and Mrs. Carpenter, Mr. A. Norman Tate and Miss Tate, Mr. A. E. Fletcher and Mrs. Fletcher, Mr. and Mrs. J. Spiller, Dr. Thos. Stevenson, Mr. C. E. Groves, F.R.S., Mr. and Mrs. Percy C. Gilchrist, Mr. and Mrs. A. H. Allen, Dr. H. E. Armstrong, F.R.S., and Mrs. Armstrong, Mr. B. E. R. Newlands, Sir Philip Magnus, Professor Meldola, F.R.S., and Mrs. Meldola, Mr. E. C. C. Stanford, Professor F. Clowes, D.Sc., Mr. Ivan Levinstein, Mr. S. B. Boulton, Dr. D. B. Hewitt, Mr. Calderwood, Mr. P. J. Worsley, Mr. John Brock, Mr. Alex. M. Chance, Mr. Eustace Carey, Mr. Jas. Duncan, Mr. S. H. Johnson and Mrs. Johnson, Mr. and Mrs. Swan, Professor Carey Foster, F.R.S., and Mrs. Foster, Dr. C. R. Alder Wright, F.R.S., and Mrs. Wright, Professor Marshall Ward, Mr. William Anderson and party, Colonel Gamble and party, Mr. D. Howard and party, Mr. and Mrs. Charles Hawksley, Sir James N. Douglas, Professor Hughes, F.R.S., Dr. W. H. Perkin, F.R.S., and party, Mr. Francis Galton, Mr. J. T. Brunner, M.P., Mrs. Brunner, and party, and numerous others.

The Prince's band, conducted by Messrs. F. R. Kinke and A. W. Cornish, performed at intervals during the evening, and the Misses Thomas gave a fine rendering upon the piano of Grieg's "Norwegian Dances" and Moszkowski's "Poland" and "German Round," the last of which was especially admired. Miss Adelaide Thomas, A.R.C.M., also gave Chopin's "Barearolle" and a "Tarantella" by Nicodé in her well-known artistic style. By 10 o'clock the rooms were so thoroughly filled that some considerable perseverance was necessary to enable the guests to examine in detail the fine collection of modern art displayed around the walls. The approaches and corridors were tastefully decorated with palms and exotics, and, thanks to the electric light, at no time during the evening was the atmosphere oppressive. The refreshments and general arrangements left nothing to be desired. The company separated shortly before midnight.

SECOND DAY.

On Thursday, July 11th, about 250 members availed themselves of a special steamer which had been provided, and proceeded up the River Thames to the Manbré Saccharine Co.'s works at Hammersmith. Here they were received by the manager, Mr. E. G. Francis, Dr. Bechler, Dr. Burnand, and Mr. C. C. Hutchinson, who escorted them round the works. The principal manufactures of this firm are invert sugar made from cane sugar, and brewers' saccharine or glucose, made from sago flour and other amylaceous substances.

After the inspection, the members partook of lunch, provided by the firm, and at the close of the proceedings a hearty vote of thanks to the Directors and Staff was proposed by Mr. David Howard, and received with enthusiasm.

The party then re-embarked and proceeded to—

THE ROYAL GARDENS, KEW.

In the absence of the Director, the members were received by the Assistant Director (Mr. D. Morris). The party was divided into groups, and under the guidance of Mr. J. R. Jackson (Curator of the Museums) and Mr. George Nicholson (Curator of the Gardens) visited the several

Museums, the Palm House, the collection of economic plants, Miss North's Gallery of Drawings, and the Arboretum with its fine collections of New and Old World species of trees.

At this point the President joined the party, which soon after divided, some proceeding to the Star and Garter by road, while others returned to the steamer to continue their journey by river. After leaving Brentford, whose well-known gas-works were concealed by a leafy eyot, Sion House, with its famous lion, and the old-fashioned town of Isleworth were passed, and later on a glimpse was obtained of the Royal Observatory in the Old Deer Park. All were much struck by the beauty of the landscape, enhanced as it was by most brilliant weather. Richmond was soon reached, and the members found their way in groups, by way of the gardens and terrace, to the "Star and Garter."

THE ANNUAL DINNER.

In the evening about 200 of the members and their friends dined together in the new ball-room of the Star and Garter Hotel, Richmond. The President, Mr. Ludwig Mond, was in the chair, supported, on the right, by Sir John Coode, K.C.M.G., President of the Institution of Civil Engineers, and, on the left, by Professor Dewar, F.R.S. The guests and visitors included the following:—Dr. James Bell, C.B., F.R.S., President of the Institute of Chemistry; Mr. Charles Cochrane, President of the Institution of Mechanical Engineers; Professor Leeds, President of the Stevens Institute of Technology at Hoboken, U.S.A.; Professor Spencer Newbury, of Cornell University, Chief of the American Commission to the Paris Exhibition; the Hon. W. Massey-Mainwaring, Chairman of the Native Guano Company; Lieut.-Colonel and Alderman Cowan; Mr. D. Morris, Assistant Director of the Royal Gardens at Kew; Mr. Henry Sharp and Mr. E. B. Ellice-Clark, Directors of Brin's Oxygen Company; Mr. W. P. Rix, of Messrs. Doulton and Co.; Mr. E. Garcke, Manager of the Brush Electrical Engineering Company, Limited; Mr. J. T. Brunner, M.P.; Mr. E. Rider Cook, Hon. Treasurer; Mr. David Howard, Chairman of the London Section; Mr. Alexander M. Chance; Mr. E. K. Muspratt; Mr. E. C. C. Stanford; Mr. John Pattinson; Professor Dittmar, F.R.S., of Anderson's College, Glasgow; and Professor J. Campbell Brown, of University College, Liverpool.

Grace having been said by the Rev. F. Relton, the company sat down to an excellent dinner.

After dinner the proceedings opened with a performance on the piano of Wallace's "Grand Polka de Concert" by Mr. F. E. Choveaux.

In proposing the first toast of the evening, "The Queen and Royal Family," the PRESIDENT said that during Her Majesty's long and happy reign the progress of science and of its applications had been even more remarkable than the progress of wealth and general culture. The Royal family, and foremost amongst them the Prince of Wales, had always followed the illustrious example of their father in appreciating and doing all in their power for the advancement of science and of the arts and manufactures of the country.

The toast having been received in the usual loyal manner, Mr. Arthur Thomas sang in excellent style "On the Zuyder Zee," and, being encored, gave the Jodel song from "Rip van Winkle."

Mr. E. RIDER COOK who, in the unavoidable absence of the President elect, proposed the toast of "The Society of Chemical Industry," said he was unexpectedly called upon to fill a position of honour but one of exceptional difficulty. He could hardly imagine an English audience more difficult to address than the Society of Chemical Industry. They were nearly all commercial men having all the acuteness engendered by the competition of the times, and, in addition, sufficient knowledge of science to distinguish real grit from anything like froth. But obedience was one of the best characteristics of Englishmen, and Mr. Tyrer was a tyrant who was willingly obeyed because he set an example of

heartily and thorough work in behalf of the Society. That must be his apology for venturing to undertake the toast of the Society of Chemical Industry, with which he would couple the name of its respected President. The Society was a comparatively new one, but it had already made its mark on the commerce of England, and had, he believed, now entered upon a course of prosperity which would enable it in the early future to deepen that impression. What were their objects in starting the Society? If he understood them rightly, one of the main objects was to substitute in the various chemical industries scientific exactness for the old rule of thumb. They wanted in this great manufacturing country to do away with the phrase "near enough." That was a phrase which he hated to hear in the factory. To his mind the only thing near enough was the exact thing wanted; and one object of the Society was to teach manufacturers to make up their minds what they wanted in their works and then to insist on having the real thing and no substitute. Another aim of the founders of the Society was to help one another as far as possible without injuring themselves. He believed that it was quite possible for even keen competitors in business to do that to a considerable extent. The little things that they could thus learn of one another's methods were helpful in saving trade expenses but did not affect the special knowledge which each man had in his own business. Another very laudable object was to enable English manufacturers to hold their own in the great contest of nation with nation. Some people thought that other nations, by means of a higher national education than England had ever attempted, were giving their workmen, foremen, and heads of departments advantages which Englishmen did not possess; and, in their own quiet way, with no political aims whatever, the founders of the Society had done what they could to compensate for the disadvantages of our national educational system. They were persevering in that course still; and though they would hail with pleasure anything that the Imperial Parliament might do in fulfilment of its duties, they would continue to do their best to make up the deficiency. He would be sorry to stop there, for the aim of the Society was not only that its members and English manufacturers generally should hold their own amongst the nations, but that by their Journal and their communications with other countries they should help forward the great progress of humanity at large, in the production of the necessities and luxuries of life with the least possible expenditure of labour and money, and thus enable every man to better enjoy his existence. These were some of the objects of that Society to which he asked his audience as patriotic Englishmen to join with him in wishing success. But he had to associate with the toast the name of their President, Mr. Mond. Mr. Mond was known all the world over as one of those fortunate men who had been very successful in business; but those who had had the advantage of hearing the address which he had given at the Annual Meeting, would agree with him that "fortunate" was not the word to use; for Mr. Mond had deserved the success which he had attained. In listening to his able description of all the attempts to manufacture ammonia from its different sources they had felt that his success had been attained not by luck but by hard work, and by bringing his powerful mind and keen intellect to bear upon the work in the best possible way. That address had taught them that commercial success could only be achieved in one way—by understanding thoroughly what one was dealing with, and then industriously pegging away until one arrived at the best possible way of dealing with it. To him, that paper was not only interesting on account of the matters it actually brought before him, but it had a charm in the visions it suggested of what might be in the future. He had been accustomed to regard the gases from furnaces as noxious bodies to be got rid of as far as possible. But when he heard the description of Mr. Mond's new battery, and was told that the gases coming from the producer were to be the means of evolving electricity at a cost compared with that obtained by the mechanical power of a steam engine or the ordinary electrical machines of 8 to 50, he was lost in wonder as to the possible developments of this new power. There was no limit to the field of research and energy before them. Young men were there, and he would

advise them to follow the example of the President as shown in his address. They knew not what discoveries were before them in the future, allowing men to be relieved from toilsome labour and permitting the necessities of life to be produced so readily as to give even ordinary labourers time not only for recreation but for the improvement of their intellects. He therefore gave as a toast worthy of their hearty reception, Prosperity to the Society of Chemical Industry, and long life, happiness, and health to its President, Mr. Mond.

The PRESIDENT, in reply, said that he thanked the company most heartily for the way in which they had received the toast of the Society, and still more for their hearty reception of Mr. Rider Cook's very kind remarks with respect to himself. He had been connected with the Society from the very beginning, and had done the best he could for it—however little that might be—and he frankly admitted that he felt very proud of the Society. During the comparatively few years of its existence it had achieved something, and there was every indication that it would achieve more, if only the younger members would follow the example and work upon the lines laid down by the founders of the Society. He saw around him a number of gentlemen who had filled the post of President before him, and all of whom had done a great deal more than perhaps the general body of members knew towards the success the Society had attained. If the younger members would go into the work with the same amount of enthusiasm, with the same understanding of the high aims before them, and of the necessity for working together to assist, as Mr. Rider Cook had well said, in the progress of the application of science to the industrial arts, not only in the interest of one country but in the interests of humanity, the Society would continue in its successful career, and its work would be blessed for a great number of years to come. Mr. Rider Cook had referred in very kind and gratifying words to the work which he had done and to the address which he had had the pleasure of delivering. He could only say that if he had been successful it was due to the earnestness and perseverance with which he had applied the knowledge that he owed to others to the task of solving some of the problems of industrial science. He would be proud, indeed, if he had succeeded in showing the younger members of the Society the way in which the solution of such problems should be attempted.

Then followed a trio for flute, violin, and piano, by Messrs. Remart, Smith, and Choveaux.

On rising to propose the next toast, that of "The Learned Societies," the PRESIDENT said that he felt that he was taking the place of a much better man, but he had just received a telegram from Sir Henry Roscoe, expressing his deep regret that important parliamentary duties prevented him from being present. He also must express his great regret that Sir Henry was absent, because he was quite unprepared for it and did not feel equal to the task of taking his place and proposing so important a toast. He was in a special difficulty about this toast, because he was not clear what "the Learned Societies" meant. Did it include the Society he was addressing? He hoped so; because it had been the earnest desire of himself and of all who had assisted in its formation that it should be a learned Society. He was not sure either whether the term included such societies as the Civil Engineers and the Mechanical Engineers, both of which he personally considered came within its meaning. At any rate, on the present occasion he proposed to assume that the term included all societies whose object was to apply learning to the benefit of humanity. He ran no risk of error in stating that the Society of Chemical Industry believed that all industrial progress must be based upon the application of scientific knowledge, and that any attempt on the part of manufacturers to get on without a sound groundwork of science must be abortive. He therefore had great pleasure in proposing this toast, coupling it with the names of Professor Dewar—their excellent friend and a most worthy representative of the Universities, and of he did not know how many learned societies; certainly the representative of the Royal Institution, by whose benevolence they had been enabled to hold their meeting under such auspicious circumstances—and of Dr. James Bell, who, as President of the

Institute of Chemistry, was an eminent representative of that science with which they were most closely connected.

Professor DEWAR, in responding, said that he thoroughly appreciated the high compliment which the President had paid him in associating his name with the learned societies. He deeply regretted that his friend Sir Frederick Bramwell was unable to be present, because he would have been a much fitter man to reply to that toast, especially as the President had referred to the use of the Royal Institution, of which Sir Frederick was the Honorary Secretary. The rooms of the Royal Institution had been granted as generously and heartily as he had expected. He could only say to those who were connected with the chemical side of abstract science and not with the Society of Chemical Industry (if there were any such), that the sooner they got into it the better. He said so because he hoped that the partnership between abstract and applied science which formed the foundations of the Society would continue as firmly in the future as in the past. It was of the utmost importance to each that that alliance should continue to exist in the closest possible manner. So far, the Society of Chemical Industry had behaved in the most generous manner to abstract science, as the list of its past Presidents proved, including, as it did, the names of Sir Henry Roscoe, Sir Frederick Abel and Dr. Perkin. It was clear therefore that the Society recognised the necessity of that union, which he trusted would long continue. In the interests of that alliance he hoped that the Society's Journal would not be too strictly confined to applied chemistry, but that it would continue to include that necessary amount of abstract knowledge which was the spirit and essence of the times. He admitted that what he was advocating tended to make the editorial duties extremely onerous; still he hoped that under the new arrangements with respect to the Editor it would be found possible to maintain that generous infusion of abstract knowledge into the Journal which he held to be necessary in the interests of the broad culture of the Society. It happened that there were among them that night representatives of abstract science from the United States as well as those of their own country. He was sure that the Society of Chemical Industry would cordially welcome Dr. Leeds and Dr. Newbury. Dr. Leeds had been to England before, and was well-known to Englishmen by his original work in both abstract and applied science; and of Dr. Newbury he need say no more than that he had come over to represent the Government of the United States at the great Paris Exhibition. He hoped that both gentlemen would take back with them to the United States a pleasant recollection of their reception by that Society. True, their American friends had a Society of the same sort at home; but he knew their love of the parent country was so great that they would not neglect the opportunity of becoming members of the Society of Chemical Industry. There were many other points which he might touch upon if time permitted; but as a matter of fact he had been led to expect that the only duty he would probably be called upon as a past President to discharge at the London meeting would be that of presiding at some musical and artistic entertainment to be given by the members and their friends. There were some who seemed to think that an office of that character suited him better than replying for learned societies. That was a point which they could decide for themselves on the occasion of the At Home of the Society on the morrow evening. At any rate, he trusted that the concert would prove to be so good as not to be considered out of place as an addendum to that evening's dinner.

Dr. JAS. BELL expressed profound regret at the absence of Sir Frederick Bramwell. He felt certain it would have been highly interesting to have heard Sir Frederick describe a few typical instances of the marvellous improvements effected by civil and mechanical engineers towards minimising labour, and diminishing the cost of production. It had been pointed out by one speaker that in competing successfully with other nations, it was not sufficient to merely obtain approximate results in manufacturing processes, but that it was absolutely necessary to obtain exact results. Manufacturers could not be too strongly impressed with the fact that the old rule-of-thumb methods had now

no chance in the industrial competitive race among nations, and that successful managers of works nowadays must be men possessed of sound scientific knowledge, and well grounded in theoretical and practical chemistry. The man who was not so qualified would unequivocally fail to exercise an intelligent control over chemical manufacturing operations, and be unable to successfully discover the causes of abnormal results. Great difficulty had hitherto existed in distinguishing between the qualified and the unqualified chemist; there was no definition of a chemist, and there was no authorised licensing body to guarantee the qualifications of a man calling himself a chemist. With the view of supplying this want, an important step had been taken by the incorporation of the Institute of Chemistry of Great Britain and Ireland, and a Fellow of that body might now be assumed to have passed through a proper and systematic course of training in theoretical and practical chemistry, and to be qualified to undertake chemical work. The Institute of Chemistry, by undertaking to guarantee the qualifications of a professional chemist, had an important bearing upon the manufacturing industries of the country; and to the Society of Chemical Industry was of especial interest and importance, from the influence which it was likely to exercise in encouraging a sound education in theoretical and practical chemistry. In conclusion, he heartily joined Professor Dewar in thanking the company for so cordially drinking to the toast of the Learned Societies.

Then followed Germain's "Bolero" admirably played on the violin by Mr. T. Harry Smith.

Mr. DAVID HOWARD, in proposing "Our Guests," said that he entirely lacked that sense of antagonism which had so strong a hold upon some orators in speaking, since in his case "our guests" were not strangers. There was a time when chemists looked upon chemistry as a self-satisfying atom; later on they came to think of it as a dyad, satisfied with the kindred sciences of heat and electricity. But they had learned better since, and now regarded it as what he might call a polyad, having an infinite number of unsatisfied affinities; in fact, they now knew that there was no science employed in the industries which was alien to their own science of chemistry. He had the honour of coupling with the toast the name of Sir John Coode, a name of the highest eminence in the great profession to which he belonged. The two sciences were intimately allied, for engineers were dependent on chemistry for the manufacture and testing of the materials they employed and relied on. He had also to couple with the toast the name of Lieut.-Colonel Cowan, eminent in the material use of scientific processes; and likewise the names of their guests from America, from whom Englishmen were separated neither by race, language, nor sympathies, and who therefore could not be regarded as strangers. Engineers might not call themselves chemists—though many of them were chemists in a measure—but they pursued the same objects as the members of that Society, profited by each other's labours and studies, and were linked together in that great whole—the industry of the civilised world.

Sir JOHN COODE said that he could quite agree with the remark made with such emphasis by Mr. Rider Cook, that there was no more diffident body of men to address than the Society of Chemical Industry. Bearing that remark in mind, he felt himself to be in a somewhat appalling position in being called upon to respond to the toast just given. However, he did respond to it with gratitude, because he felt that it was no light matter to be invited down to a beautiful spot like Richmond and entertained in the manner in which he and his fellow-guests had been. That was the least he could say, but even if he said much more he should still fail to convey all that he felt. He heartily endorsed what Mr. Howard had said with respect to the connection between the Society he was addressing and civil engineers. He as an engineer knew how very much they owed to chemical science. He was pleased to learn that the Society numbered so many members; it was little more than an infant in point of age, but a growing and prosperous infant, and one which he trusted would progress in the future even more than in the past. He was glad to hear Professor Dewar's

remarks about the Society's Journal, which he hoped to be able to look into occasionally and learn a great deal therefrom. On behalf of the visitors and for himself, he begged to return heartfelt thanks for the kind manner in which they had been received and entertained by the Society.

Lieut.-Col. and Alderman Coway was deeply gratified by the kind way in which his name had been received. This was the last occasion on which he would have the honour of being with the Society as a guest, for the Secretary had just informed him that the additional honour of being elected a member of the Society had been conferred upon him; therefore, although he hoped to be present at many similar gatherings of the Society in future, it would necessarily be in a different capacity. Many of the previous speakers had referred to the learned societies and to the progress of science. For his own part, he had always felt that the advancement of art, of manufactures, and of commerce must be limited by the power of the country to take advantage of the applications of science. He was old enough to recollect the manufactures of 30 years ago, and had kept some reminders of his own particular industry. To look at those objects had much the same effect on him as an inspection of the Ark might be expected to produce on a modern shipbuilder. Might we then take a suggestion from that, and think what the historian of the future would say of the manufactures of the present day. He hoped, and felt, it would be something to this effect:—In the year 1889 we saw England as of old in keen competition with the entire world. Her great natural powers of which she had always been so justly proud still stood her in good stead, but side by side with these she had enlisted a new ally, and science was made to march in the van abreast with industry. Science and erudition were no longer hidden mysteries, but were to be seen broadcast in the land, adding by their beneficent influence to the progress and greatness of the country. It was thus that England, no longer relying on the sword, but confident in her new alliance, was able to challenge all comers, and to emerge with success and triumph from the competition. He thanked them for the honour done to him that evening, for the honour of being elected one of their body, and for the honour conveyed by their proposed visit to his works on the following day.

The President said he could not suffer the company to leave without asking it to drink the health of the Secretary of the London Section of the Society, their friend Mr. Tyrer, to whom they were all indebted in the highest degree for that very pleasant and successful meeting.

The toast having been enthusiastically pledged with full honours, Mr. T. TYRER said that at that late hour it would ill become him to do more than thank the President and the company sincerely for the kind manner in which his health had been proposed and received. A large number of gentlemen had contributed to the success of the meeting, and their names appeared on the programme; but in the performance of the responsible duties of Honorary Secretary of the London Section of the Society he had had the able assistance of two gentlemen whose names did not appear, the General Secretary of the Society, Mr. Cresswell, and Mr. Peirce. The Committee of the Section had permitted him to delegate as much of the work as possible; and his own share of the work might really be summed up in three words—to ask, to negotiate, and to complete. All the details of the work had been done thoroughly and well by Mr. Peirce, aided, guided, and counselled by the General Secretary, Mr. Cresswell. Honour to whom honour was due. He therefore could not allow the President to thank him for work which he had not really done. Nor could he sit down without saying that the thanks of the members were due above all to the President, who had given him *carte blanche* with respect to all the arrangements for the conversation, and also to the Committee of the London Section.

THIRD DAY.

MESSRS. TRUMAN, HANBURY, AND BUXTON'S BREWERY.

On Friday morning about 50 members paid a visit to Messrs. Truman, Hanbury, and Buxton's brewery in Spitalfields. This establishment has always taken a leading position among the English breweries, and at present ranks next after Guinness', Bass', and Allsopp's in productive power. It covers an area of over six acres, and when in full work the daily output is 2,000 to 2,500 barrels. Over 10,000 tons of coal are consumed per annum, and between 700 and 800 men and about 200 horses are employed. The stores contain 15,000 quarters or 45,000 cwt. of malt, and a proportionate quantity of hops. The water is derived chiefly from a well 850 ft. deep, with headings 200 ft. deep, and extending 150 ft. outwards. In the short time at the disposal of the visitors it was impossible to make a thorough examination of the vast building and all its admirable apparatus and appointments; but a good general inspection was made under the courteous guidance of Mr. Snelling, chief of the brewing department, and Mr. Jeffers, chief of the stores. Commencing with an inspection of the cask washing and cooling yards, the party was next led to the handsome and well-appointed range of stables, which afford accommodation for about 200 horses, the official name of each animal being painted over its stall. From the stables the visitors proceeded to the mashing house, where four gigantic tuns were in operation. Some 600 quarters of malt were here under treatment, the capacity of the largest tuns being 160 qrs. Leaving the mashing tuns (and passing on their way the celebrated Tuke's self-feeding smoke-consuming furnaces, which Messrs. Truman, Hanbury, and Buxton began to use in 1848 out of pity for the then flourishing silk industry of Spitalfields, but which have proved so economical in their operation as to have saved the firm 100,000*l.* in coal alone), the visitors made an examination of the seven huge coppers into which the wort is pumped direct from the mashing tuns, to be boiled with the requisite quantity of hops. After passing through the vast hop stores, fragrant with the golden produce of Kent, the party followed pretty closely the progress of the wort, by the strainers, in which the spent hops are separated out, up to the cooling loft at the top of the building, an area of 35,000 sq. ft., divided into four shallow compartments of copper, over which a current of cool air constantly passes. Descending again, they entered the refrigerating room, containing seven large machines, in which the wort is rapidly cooled from about 140° to about 60° F. A floor lower they entered one of the vast fermenting rooms and saw this critical portion of the brewer's work in all its stages. The process of fermentation is now chiefly carried on in slate tanks, of which there were over 50 in this one room, of an average capacity of about 150 barrels; but in a room subsequently entered were to be seen four "fermenting vats," leviathans of the old school, of most portentous appearance, and each capable of holding 1,400 barrels. After the "fermenters" came the "cleansing backs," shallow slate vessels in which the liquor settles, while the yeast is skimmed off and run down "parachutes" into slate vessels beneath, where sufficient of it is preserved for future operations, the rest, after passing through filter-presses, being exported to France for use in the distillation of spirit. This was the last operation to be seen, since the finished beer, after leaving the cleansers, is run, if "black," into huge vats for maturing, and if ale, into casks ready for consumption. Leaving the brewery, therefore, the visitors were now conducted through the spacious, and apparently endless, store-rooms, in one of which they found luncheon awaiting them, and at once formed themselves into a sampling committee for the purpose of fully testing the various products, black, brown and golden, the genesis of which they had so industriously traced.

After luncheon, Mr. A. H. Allen moved a vote of thanks to the firm of Truman, Hanbury, and Buxton for their kindness in affording the members an opportunity of visiting their great and historic brewery and of seeing for themselves "how much science was put into a glass of ale," and to

Mr. Snelling and Mr. Jeffers for their efforts in making the visit so thoroughly pleasant and instructive. The vote was carried enthusiastically and was briefly responded to by Mr. Snelling on the part of the firm.

MESSRS. COWAN'S SUGAR REFINERY.

About 20 members proceeded to Messrs. Cowan's sugar refinery, where they were received by Lieut.-Col. Cowan and his son. In the laboratory they were first shown the details of the various processes of sugar refining on a small scale, from raw beet-sugar to fine white. They were then taken over the works and shown each process on the large scale, including the manufacture of animal charcoal and its revivification, and the manufacture of tar and gas from the waste products, the last being consumed on the premises. After inspecting the furnaces, with their mechanical feed, and the engines, the party proceeded to the soap factory with its stock and packing departments. The greater part of the works were unfortunately in a very unfinished state, owing to the recent fire, but are being replaced as rapidly as possible by absolutely fireproof constructions. A vote of thanks proposed by Mr. Thos. Christy was received with acclamation.

THE KINGSTON SEWAGE WORKS.

About 40 members availed themselves of the invitation of the Native Guano Company, Limited, to visit these works, where the sewage of Kingston and Surbiton is treated by the well-known system of this company. In the unavoidable absence of the Hon. W. Massey-Mainwaring, the chairman of the company, they were received by Mr. W. Cameron Sillar, a director, Mr. W. Stevens, secretary, and Mr. C. E. Robinson, the engineer.

The company claim for their process:—

1. That the effluent water therefrom is sufficiently purified to be admissible into any river within the requirements of the Rivers Pollution Prevention Act, and without injury to fish.
2. That this is effected without nuisance.

3. That the materials used in the process do not injure or destroy the manurial qualities of the sewage, which are consequently preserved for agricultural use in a dry, portable, and inoffensive form.

The sewage is received in tanks, in its passage to which it receives, first, a mixture of clay, charcoal, and a small quantity of blood or other glutinous body capable of coagulation, and secondly, a solution of crude sulphate of alumina distributed in such wise as to secure thorough intermixture. In its progress through the tanks the matter in suspension goes to the bottom, while the clear supernatant fluid passes away into the river without filtration or any other subsequent treatment. The tank room requisite is only about what would be required for one day's supply of sewage, and accordingly a very limited area of land is required. The addition of the charcoal and clay at once arrests all offensive odour, no matter how foul the sewage may be, and this freedom from nuisance continues throughout the whole of the process. The tanks are cleaned periodically. The deposit or "sludge" is pumped into filter-presses where the superabundant moisture is removed, and further dried by artificial heat till it assumes the appearance of dry earth, when it is ready for market. One feature of this process is that no lime is used at all, unless a test shows the sewage entering the works to be abnormally acid from manufacturing refuse, in which case it is, of course, necessary to neutralise it, and consequently the effluent always remains on the acid side of neutrality; a condition unfavourable to secondary fermentation, and hence sewage fungus.

At the conclusion of the inspection the party adjourned to luncheon, where, in response to a vote of thanks proposed by the general secretary, Mr. Cameron Sillar explained the rationale of the process and how each purifying agent worked. Alluding to the clay, he said that their process might be described as the reverse of irrigation, for they brought the earth to the sewage instead of the sewage to the earth. The charcoal used was a waste product of another manufacture, and, in fact, the sulphate of alumina was the only chemical used which could not be had at the mere cost of carriage.

The accompanying sketches show a front view of the buildings and a block plan of the works. The Kingston sewage on reaching the works passes into the screening

chamber and through a grating, which intercepts coarse matter likely to choke or injure the pumps, and thence through a culvert to a pump-well under the main building, where it receives the clareoal, clay, and blood. The sewage thus partially treated is raised about 12 feet by centrifugal pumps, of which there are three, each driven by a 15 horse-power engine and capable of lifting 1,650 gallons per minute. The pumps discharge into a meter chamber where the sewage is measured and the quantity registered. On leaving the meter the sewage flows along an open channel to the settling tanks, receiving on its way the precipitating agents. There are eight tanks, each 85 feet long by 50 feet broad and 6 feet average working depth, holding 450,000 gallons, or 1,200,000 gallons in the aggregate, which gives a capacity of 30 gallons per head for a population of 40,000. The treated sewage flows in a continuous stream through the tanks, precipitating as it flows, and passes clear, bright, and odourless into a covered channel discharging into the Thames. The tanks are cleaned periodically, the deposit or "sludge" being pumped into the sludge-well by a Tangey-Holman double-action pump at the rate of 500 gallons per minute. From this well the sludge is first drawn into four sludge vessels, or accumulators, by the creation of a vacuum, and is then forced by air pressure, at 100 lb. on the square inch, into filter-presses on the first floor of the building, from which it is removed in hard cakes. There are two of Scott's air pumps and 11 of the Native Guano Company's filter-presses. The pressed cakes are dried in a Borwick's drying cylinder (with fan and condensing apparatus attached), ground into powder, and sold as Native Guano. The Surbiton sewage is separately received and screened, and is pumped by centrifugal pumps, through a meter, into the Kingston pump-well. There are three pumps, each driven by an 8 horse-power engine, and capable of lifting 750 gallons per minute. The boilers are of the locomotive multitubular type, working at a pressure of 150 lb. per square inch—one of 80 horse-power and two of 60 horse-power each. The two main-driving engines, each of 40 horse-power, are used alternately, and, like the pump-engines, are of Messrs. Willans and Robinson's patent kind. Two mortar mills are used for grinding the deodorisers, which are then mixed in vats and discharged into the pump-well; and there are two vats for dissolving the precipitating agents. A small centrifugal pump supplies water from the river for the boilers, mixing the chemicals, &c. The works have been constructed for treating, by the Native Guano Company's processes, the sewage of 35,000 people; but with certain comparatively inexpensive additions, they will meet the requirements of a population of 50,000.

At present the sewage being treated is	
that of Kingston, with a population of	26,156
And of Surbiton, with a population of	11,912
Total	38,068

In a short time Hampton Wick (population 2,500) will send its sewage over the railway bridge to these works by one of Shone's ejectors.

THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION, LIMITED.

On Friday afternoon about 50 members visited the Brush Electric Light Works and inspected the various methods of manufacture employed by that corporation, and the working of various pieces of electrical apparatus.

The following attracted most attention:—Electric locomotives for tramway work. These locomotives, made for tramways in different parts of the world, are driven by "Victoria" motors geared down to the axles of the cars by special gearing, of which the principal novel feature is a magnetic coupling designed by Mr. J. S. Raworth, the Brush Corporation's superintending engineer. This coupling takes the place of the clutch or friction coupling which has sometimes been employed for such purpose, but has the great advantage that it can be put in or out by merely making a contact. It is arranged to connect the motor through one

or other of two sets of gear in order to obtain the advantage of high speed and large output whether the cars are running up-hill at a slow rate or on the level at a high rate of speed. The visitors next inspected the "monkey" running on a line on the overhead system. The object of this "monkey" is to maintain continuously a connexion between the line and the car. In another case accumulators are being used to supply power to the motors, the cars being in this case independent of a connexion with the generating station. The visitors also inspected a number of engines under test, driving dynamos particularly intended for ship lighting. A number of "Brush" and "Victoria" dynamos were seen either in testing or in course of construction. The alternate current apparatus of the corporation was represented by the "Mordey-Victoria" alternators, transformers, automatic regulators, and the "Brush" alternate current arc lamp. All this apparatus was being manufactured on a large scale, and the visitors had an opportunity of seeing some of it in operation.

BRIN'S OXYGEN COMPANY.

About 150 members assembled at these works, where they were received by Mr. Henry Sharp, chairman, Mr. Ellice-Clark, managing director, and Mr. Elias, director. Mr. Ellice-Clark, in welcoming the visitors on behalf of the company, pointed out that the works were mainly experimental and therefore were naturally not extensive. The directors, when they took the exploitation of these patents in hand, were desirous of showing manufacturers and others that the extraction of oxygen and nitrogen was not a mere laboratory experiment, but that it was undoubtedly a continuous and industrial process, and one which might be carried out in their own factories. And in spite of great practical difficulties—which members as manufacturers would readily appreciate—and also, he was sorry to say, of considerable prejudice from quarters where it ought hardly to have been expected, he thought they would be able to show members that the process was a perfectly practical and also an economical one. For the benefit of those members who might not be quite familiar with the process, he might say that oxide of barium (prepared in a porous condition from the nitrate) was introduced in pieces about the size of walnuts into steel or cast-iron retorts. These retorts, placed in a vertical position in a gas furnace, were heated to about 1,400°, and air, carefully purified from moisture and carbonic acid, then pumped through them under a pressure of about 15 lb. on the square inch. The baryta absorbed the oxygen, becoming converted into barium peroxide, and when this peroxidation was completed or carried as far as is found in practice to be economical, the pump was reversed and the pressure in the retorts thus reduced. As soon as the reduction of pressure had reached about 26—28 in. of mercury below the normal, the peroxide began to give up its oxygen (becoming reduced again to the monoxide) which passing through the pump was delivered into a gas-holder. A complete operation (oxidation and deoxidation) lasted about 10 minutes, at the end of which time the operation commenced *de novo*. Nearly 140 operations were thus made a day. The life of the baryta was a very long one, and in fact at first it actually improved by use. As a rule oxygen of about 96 per cent. purity was made, and what may be called commercial oxygen of a purity of over 90 per cent. sent out. When the gas was wanted for distribution at a distance it was drawn from the holder by a compression pump which forced it into steel cylinders under a pressure of 120° atmospheres.

The members, in parties of about 25—30, were then conducted over the works by Mr. Henry Sharp, Mr. Ellice-Clark, Mr. Ellice Elias, Mr. K. S. Murray (assistant engineer), and Dr. Thorne (chemist). Here the chief improvement which has been effected of substituting vertical retorts and a constant temperature (change of pressure only being relied on) for horizontal retorts and changing temperatures was pointed out. Attention was also called to the precautions adopted for preventing accidents in the compression of coal gas and oxygen by the use of separate compressors and differently coloured cylinders for each gas. The applications of oxygen to the

purification of gas, to bleaching, to the maturing of spirits, &c. (see this vol., p. 82), were also referred to. In proposing subsequently a vote of thanks to the directors, Mr. D. Howard said that Brin's oxygen process was of special interest to chemists, not from the size or complexity of the plant employed, but from the very simplicity of the arrangements which had triumphed over difficulties which were either unknown or thought little of in the laboratory stage of the researches. These difficulties, unless they had been met by most skilful treatment, must have been utterly fatal to success. It was but one more example of the great lesson of industrial chemistry, viz., that practical difficulties only began when theory scored a success.

GROTH'S ELECTRIC TANNING PROCESS.

A few members visited the works of Messrs. Tebbitt Bros., Bermondsey, to inspect a new process of electric tanning, the invention of Mr. L. A. Groth. In an empty tanning pit was placed a circular vat with revolving gear on which were suspended raw hides, presumably in tan liquor. Adjoining this was a dynamo, wires from which were connected with copper plates inside the vat, and it was claimed by the inventor that the electric current so produced shortened the time of tanning from three months to about one month. Further details of this process will be awaited with interest.

The proceedings of the Annual Meeting terminated with a smoking concert at the Café Monico, conducted by Mr. J. C. Butterfield, who was assisted by some talented artistes and a quartette party. The President occupied the chair, and a most high-class and enjoyable programme was provided.

Thos. Tyrer, Garden Wharf, Battersea, S.W.

Meeting held Monday, May 6th, 1889.

MR. DAVID HOWARD IN THE CHAIR.

NOTES ON EXPLOSIVES.

BY C. NAPIER HAKE.

GLANCING briefly at the past history of the subject, it will seem that until comparatively recently, perhaps within the memory of many here present, gunpowder was practically the only explosive in use, both for industrial and military purposes. Although it no longer holds this unique position,

it is by no means superseded nor, curious as it may seem, is it likely to be at present. There is certainly no explosive known which lends itself so easily to so many and such varied purposes. To use Mr. Alfred Nobel's words,* "In a mine it is used to blast without propelling; in a gun to propel without blasting; in a shell it serves both purposes combined; in a fuse, as in fireworks, it burns quite slowly without exploding. Its pressure exercised in those numerous operations varies between 1 oz. (more or less) to the sq. in. in a fuse, and 85,000 lb. to the sq. in. in a shell. But, like a servant of all work, it lacks perfection in each department, and modern science, armed with better tools, is gradually encroaching on its old domains." The discovery of gun cotton, in 1846, was the commencement of a new epoch in explosives. Although at first taken up eagerly by all European Governments, it was for a time abandoned after 20 years of severe testing. The disastrous experience of these 20 years was due to an imperfect chemical knowledge of its properties and to the absence of good methods of manufacture.

In 1847, almost simultaneously with the discovery of gun cotton, nitroglycerin first made its appearance, but for the same causes it fell into disrepute, leaving behind it even a worse record of disaster than its predecessor, gun cotton. But this was only for a time; the patient and courageous labours of Sir Frederick Abel as regards gun cotton, and of Mr. Alfred Nobel as regards nitroglycerin, brought these powerful agents under control, and demonstrated the conditions under which they are chemically stable; the application of the principles of detonation to them was the finishing touch to a great work. Since that period, and up to the present time, gun cotton and the nitroglycerin class of explosives have held the first position wherever a powerful agent is required. Many attempts have been made to displace them, and yet one cannot at the moment point to any serious competitor; but a vast field of research has been opened, and there is no lack of labourers adding day by day to our knowledge of the subject.

Leaving history, and before entering upon the more practical portion of my paper, I should like to glance briefly at the theory of the subject. Let us consider for a moment what is meant by the term explosive. An explosive may be defined as any solid or liquid substance or compound, which on the application of heat or shock becomes very rapidly converted, either wholly or partially, into the gaseous state with the evolution of heat.

Explosives may be conveniently divided into two classes, generally known as "high" and "low" explosives. The former are the more powerful, and their explosion is usually effected by "detonation," and is, consequently, very rapid; the latter are usually exploded by simple ignition, and their explosion proceeds progressively by combustion. Dynamite may be taken as a type of the former, and gunpowder as a type of the latter class. It is, however, not easy to hold strictly to this classification since, under certain circumstances, the terms may become practically interchangeable.

Detonation may, for practical purposes, be defined as the (almost) instantaneous resolution of an explosive into other forms of matter, chiefly permanent gases occupying many times the original bulk of the explosive, and hence exerting enormous power; it is usually induced by the ignition of an explosive of the fulminate class.

In examining an explosive, its chemical composition should first be ascertained, and from this, in the light of our present experience, it is possible to draw many inferences, such, as for example, the products of its decomposition, the quantity of heat, and the nature of the gases evolved, its probable effectiveness as an explosive, its stability, and its sensitiveness to concussion and friction. To arrive at its chemical composition presents, comparatively speaking, the least difficulty. It is not so easy to arrive at a correct conclusion as regards its products of decomposition. What is specially required is the equation of its decomposition under conditions most favourable to the production of the maximum effect as an explosive; from this equation may be

* On Modern Blasting Agents, by Alfred Nobel, 1878.

calculated according to well-known laws the quantity of heat evolved by the decomposition and the volume of gases produced. But the many and varying conditions which influence the mode of decomposition of different substances, the difficulty of determining high temperatures with accuracy, the complication of thermo-chemical laws, and many other considerations, interfere with the absolute correctness of the result. Nevertheless, a very fair relative one is obtainable. Chlorate of potassium and nitrate of ammonium are examples of the varying decompositions of certain compounds under varying conditions, the latter being capable of decomposition in no less than seven different ways.

To determine the theoretical effectiveness of an explosive it is necessary to know two things :—

1st. The volume and temperature of the gases evolved :

2nd. The quantity of heat evolved by the chemical change occurring during the explosion.

The effectiveness of an explosive is dependent on the volume of the gases evolved, the amount of heat generated, and the rapidity of the explosion. The pressure is due to the gases evolved, and is dependent on their volume and temperature. The work done is dependent on the amount of heat evolved, and may be expressed by the formula $123 M$, where M is the number of units of heat evolved. These factors are modified favourably or otherwise by a variety of conditions, such as the chemical nature of the explosive, the rapidity of the chemical change, or by the method of firing, whether by ignition or by detonation. Time is therefore an important factor. Dissociation modifies the effect of an explosive by diminishing the initial pressure, but does not affect the total thermal value, as the heat which is absorbed in the first instance is reproduced by the union of the dissociated elements as the temperature falls. The pressure is the factor which produces rupture of the envelope, but does not necessarily produce any extended mechanical effects, such as smashing or dispersion. This last, as already said, represents the heat equivalent or work. What may be termed the "power of an explosive" is influenced by the rapidity of the chemical change on explosion, and of two explosives evolving the same amount of heat, and therefore the same amount of work, that explosive which is the more rapid does that work in a shorter time, *e.g.* :—Fifteen tons lifted 1 ft. high represents the same amount of work done whether we do it in a second, a minute, or an hour; but the power necessary to do it in one minute we call a horse power; if we wish to do it in a second, we require 60-horse power.

Further, rapidity of detonation, or the velocity of propagation of what Berthelot has termed the "explosive wave," is another important consideration. An illustration of the difference with which the velocity of molecular transformation can be transmitted is exemplified by the behaviour of blasting gelatine, for instance, under various circumstances. If we light a small portion it smoulders away. On the contrary, if more strongly heated, it burns more rapidly, but in both cases the combustion proceeds at a slow rate from layer to layer, and the mechanical effects are nil when unconfined. If we detonate a similar cartridge, also unconfined, the results are very different; great mechanical effect is produced, because the decomposition is almost instantaneous. In fact the detonation is transmitted with enormous rapidity throughout the entire mass.

The actual velocity of the explosive wave has been measured, and has been found to be from 5—6,000 inches per second for gun-cotton, and about 5,000 metres per second for dynamite. At this rate the explosion of a cartridge a foot long would only occupy $\frac{1}{24,000}$ th part of a second, while a ton of dynamite cartridges about $\frac{1}{2}$ diameter, laid end to end, and measuring one mile in length, would be exploded in one quarter of a second by detonating a cartridge at either end.

The theoretical efficiency of an explosive cannot in practice be realised in useful work for several reasons, as, for instance, in blasting rock :—

(1.) Incomplete combustion.

(2.) Compression and chemical changes induced in the surrounding material operated on.

(3.) Energy expended in the cracking and heating of the material which is not displaced.

(4.) The escape of gas through the blast hole and the fissures caused by the explosion.

The useful work in blasting consists partly in shattering the rock and partly in displacing the shattered masses. The proportion of useful work obtainable from the employment of explosives has been variously estimated at from 14 to 33 per cent. of the theoretical maximum potential. For the purposes of comparison it does not matter whether we take the theoretical or practical efficiency of an explosive, since these stand in the same relation to one another, as will be seen from the following tables :—

MECHANICAL EQUIVALENT OF EXPLOSIVES.

Roux and Sarrau.

	Theoretical Work in Kilos.	Relative Value.
Blasting powder with 62 per cent. KNO_3 ...	242,335	1.0
Dynamite with 75 per cent. nitroglycerin ...	548,250	2.26
Blasting gelatin with 92 per cent. " ..	766,813	3.16
Nitroglycerin.....	794,563	3.28

Relative value of—

Dynamite.....	1.0
Blasting gelatin	1.4
Nitroglycerin.....	1.45

In this connexion the following records are also of interest :—

	Dynamite.	Blasting Gelatine.
St. Gothard's railway.....	1.0	1.16
Tenkeroda mine	1.0	1.45
Tarnowitz excavation.....	1.0	1.41
Mansfelder "	1.0	1.33
Mean.....	1.0	1.41

Experiments made in lead cylinders gave the relative value of—

Dynamite	1.0
Blasting gelatin	1.4
Nitroglycerin	1.4

The stability of an explosive is of first importance. Decomposition may occur either spontaneously or through the aid of some foreign agency. The stability of an explosive is dependent on :—

Firstly. Its chemical constitution.

Secondly. Its freedom from certain impurities.

Some explosive compounds when properly manufactured show no tendency to decompose under ordinary conditions, as for example nitroglycerin or gun-cotton. Conditions which influence the neutrality of these explosives, however, are favourable to their spontaneous decomposition.

A solution of dinitrobenzene in fuming nitric acid, though a very powerful explosive, and not dangerous in itself as regards liability to decomposition, would be a source of danger to certain other explosives stored with it, in so far as their neutrality would be endangered by the absorption of acid fumes.

As an instance of spontaneous decomposition of two compounds, in themselves fairly stable, may be noted chlorate of potassium and nitrate of ammonium. These two powerful oxidising agents react rapidly on each other with the evolution of chlorine compounds, and in the presence of a combustible and under otherwise favourable

conditions the heat evolved is sufficient to cause explosion. Again, experience has shown that nitrate of ammonium and gun-cotton are more or less incompatible owing to a tendency to spontaneous decomposition. Sulphur and iron or sulphur and zinc, when mixed together under favourable conditions, react on each other with evolution of heat sufficient to ignite gunpowder, and this has actually occurred in firework compositions.

For these reasons explosives which from the nature of their constitution have a tendency to generate or evolve acid fumes, or otherwise possess elements of an objectionable nature as regards their influence on stability, are dangerous.

Sensitiveness to concussion or friction or to ignition is another form of expression for instability under somewhat different conditions. The two are however very much governed by the same laws. Broadly speaking, the sensitiveness of an explosive as of any chemical substance is directly as the heat evolved by its decomposition and inversely as the temperature of its decomposition. A chlorate mixture is therefore more sensitive than a nitrate mixture. The law is, however, modified by the physical character of the explosive substance; for instance, fulminate of mercury in a finely-divided state is extremely sensitive to concussion or friction, yet large crystals of the same material are far more sensitive to the same treatment. Elevation of temperature tends as a rule to increase the sensitiveness of an explosive; yet blasting gelatin becomes more sensitive to concussion and friction when in the frozen condition.

I will conclude these theoretical considerations by one more reference to detonation. As before stated, the usual method of ignition employed for low explosives, of which gunpowder is a characteristic type, is a fuse. "High" explosives, on the other hand, are almost always detonated. The best agent for this purpose is found to be fulminate of mercury, and there are special theoretical reasons why this should be so. Fulminate of mercury possesses the following composition, $C_2N_2HgO_2$, and yields on detonation $(CO)_2$, N_2 , Hg . It explodes at a temperature of $360^\circ F$. It is also readily exploded by concussion or by friction, such as scratching it with a pin or by contact with strong nitric or sulphuric acid. It appears, therefore, that no compound liable to dissociation is formed, and therefore no influences exist which would tend to moderate the expansion of the gas and diminish the violence of the initial shock. Generally speaking one may say that it is neither the volume of gases disengaged nor the heat evolved which gives to fulminate of mercury its peculiar character or special advantages, for it is surpassed in both these directions by many other explosive bodies. Its superiority is demonstrated best when in close contact with an explosive, and its effectiveness is due to three causes:—

Firstly. Its nearly instantaneous decomposition by simple inflammation, even when but slightly confined.

Secondly. The almost total absence of dissociation products.

Thirdly. Its great density.

By reason of these conditions the definite products of the reaction appear to form all at once before the gases have had time to expand to a volume greater than that of the original solid.

Passing on to a more practical consideration of the subject, I do not propose to dwell on explosives generally, but only to describe such as are actually in practical use. Those wishing to know what has been suggested in the past with regard to explosives would do well to consult Major Cundill's "Dictionary of Explosives."^{*} In this valuable little book between 300 and 400 suggestions for explosive mixtures are recorded and fully described.

The following table is taken from this work, and shows the mode of classification and the number of varieties of each class:—

	Varieties.
Gunpowder	16
Nitrate mixtures other than gunpowder	63
Chlorate mixtures	67
Nitro-compounds containing nitroglycerin	82
Gun-cotton and other nitro-compounds	64
Picric powders	11
Sprengel explosives	5
Miscellaneous explosives, including fulminates	49

Many of these are mere chemical curiosities, and the large majority, for some reason or other, have never advanced beyond the experimental stage.

Looking at this table, it is obvious that gunpowder no longer retains its supreme position. It is, however, still largely used for mining purposes, especially where a slow explosive is required.

Modern activity in the invention of new explosives has no doubt broken through the monopoly which gunpowder so long enjoyed, but it has also brought forth many new and valuable improvements both as regards the composition and manufacture of this explosive.

I am aware that gunpowder deserves far more attention than I am able to give to it in this paper; but its new varieties are so numerous and its application so varied both for civil and military purposes, that it would be impossible to enter into detail in an essay of necessarily restricted length without excluding matter of, at the moment, greater interest.

In Major Cundill's "Dictionary of Explosives" 67 chlorate mixtures are described, and of these only one, to my knowledge, has been authorised. In the report of Her Majesty's Inspectors of Explosives for 1886, Dr. Dupré, F.R.S., who from his long connexion with the Explosives Department has an exceptional experience as regards the properties of explosives, says as regards dangers in the use of chlorate of potassium:—

"Chlorate of potassium, on account of the readiness with which it lends itself to the production of powerful explosives, offers a great temptation to inventors of new explosives, and many attempts have been made to put it into practical use, but so far with very limited success only. This is chiefly owing to two causes. In the first place, chlorate of potassium is a very unstable compound, and is liable to suffer decomposition under a variety of circumstances, and under, comparatively speaking, slight causes both chemical and mechanical. All chlorate of potassium mixtures are liable to what is termed spontaneous ignition or explosion in the presence of a variety of materials, more particularly of such as are acid; and all chlorate mixtures are readily exploded by percussion, such as a glancing blow, which might easily, and would often occur, in charging a hole. In the second place, there is some evidence to show that this sensitiveness to percussion and friction increases by keeping, more especially if the explosive is exposed to the action of moist and dry air alternately. If inventors would only keep these characteristics of chlorate mixtures in mind they would frequently save themselves serious disappointment."

The picric powders are few in number, and form a subdivision of the great nitro-compound class. With the exception of picric acid itself, no practical importance can at present be attached to this class of explosives. The fact that picric acid without the addition of oxidising agents forms a powerful explosive when fired by a detonator, was pointed out by Dr. Sprengel, F.R.S., in 1873, in his well-known research on a "New Class of Explosives." It is supposed to form an ingredient of the French military explosive melinite, the composition of which is kept secret. In 1885 M. Turpin patented the application of picric acid as an explosive for military and other purposes. Its comparative inertness under ordinary conditions and high density (1.6) gives it certain advantages as a filling for shells. For blasting purposes, however, it has the objection that it gives off actively poisonous gases and forms carbonic oxide on combustion, owing to a deficiency of oxygen in its composition.

^{*} A Directory of Explosives, by Major Cundill, R.A.H.M., Inspector of Explosives. Royal Artillery Institution, 1889.

In consequence of a disastrous explosion* which occurred at a chemical factory near Manchester, and which was brought about by the accidental mixing of picric acid and litharge in a molten state during a fire, picric acid has, by an Order in Council, been brought within the scope of the Explosives Act as regards manufacture and storage except when—

“(a.) It is wholly in solution.

“(b.) When it is not wholly in solution, but is being manufactured or stored in a factory, building, or place exclusively appropriated to the manufacture or storage of picric acid, and in such manner as effectually to prevent any picric acid from coming into contact (whether under the action of fire or otherwise) with any basic metallic oxide or oxidising agent, or other substance capable of forming with picric acid an explosive mixture or explosive compound, or with any detonator or other article capable of exploding picric acid, or with any fire or light capable of igniting picric acid.

“Moreover, all picrates or mixtures of picric acid with any basic metallic oxide, &c., as detailed in (b.) are to be deemed explosives within the meaning of the Act for all the purposes of the said Act unless such picrates or mixtures be wholly in solution.”

Although from the above list of explosives the number appears large, the number in practical use in this country is very small, and may be taken under three headings, namely,—

1st, gunpowder.

2nd, gun-cotton and other nitro-compounds.

3rd, nitro-compounds containing nitroglycerin.

The explosives included under the Sprengel class, although re-patented from time to time by various “inventors,” appear to be all covered by Dr. Sprengel’s original patents Nos. 921 and 2462, 1871. For practical reasons bearing on the safety properties of this class of explosives, none of its varieties have been authorised in this country. Dr. Sprengel’s researches, however, must be looked upon as most valuable contributions to our knowledge of explosives generally, and there can be but little doubt that the new class of explosives, of which bellite is a typical representative, is more or less the outcome of these researches.

Gun-cotton is essentially a military explosive. In the compressed form its density is about 1·0, and when properly manufactured, it shows no tendency to decompose. When wet it is non-sensitive to ordinary concussion or friction. It may, however, be exploded by a dry primer of the same material, even when saturated with water. For these reasons it possesses special advantages for all military and naval operations in which a violent explosive is required. But for the discovery of nitroglycerin, gun-cotton would, no doubt, have played an important rôle in mining operations. In this direction, however, it has not kept pace with its development and utilisation for war purposes. Its chief objection for blasting purposes is that it is deficient in oxygen, the disengaged products of the explosion containing large quantities of carbonic oxide (28·5 per cent.). This particular drawback has been overcome by incorporating with it nitrate of potassium or nitrate of baryta, the oxygen contained in these salts effecting a more complete combustion, and rendering the resulting gases less obnoxious than those resulting from pure gun-cotton. Special preparations in this direction have been introduced under the name of “Potentite,” “Tonite,” &c., and are used with considerable success as blasting agents.

Nitroglycerin compounds, however, take the first rank as blasting agents, their superiority lying chiefly in their cheapness, greater strength, and density. The manufacture of nitroglycerin is a comparatively simple process, and is fully described in technical works. The features of the process which are of the greatest importance are the purity of the glycerin, strength of the acids, and the complete washing of the finished product. Rapidity of working

depends largely on the strength of the acids, since the heat evolved is least when the strongest acid is employed. The output is increased, the action goes on more uniformly, and is more easily controlled.

Pure nitroglycerin (nitroglycerol) is a colourless mobile liquid possessing a definite composition. Its specific gravity is 1·26 at 60° F. When ignited in small quantities, it burns slowly away. When heated, however, to a temperature of 370° F. it explodes with great violence. When spread in thin layers it is extremely sensitive to slight concussions or blows. At a temperature of 40° F. it takes the crystalline form, and becomes solid and contracts one-twelfth of its volume. In this condition it is far less sensitive to blows and concussions than in the liquid form. One litre of nitroglycerin produces, when exploded under the most favourable conditions, a volume of gas equivalent to over 10,000 litres. The application of nitroglycerin, or of any liquid or semi-liquid compound, or mixture of the same, as an explosive agent, has been almost universally abandoned, and in this and most other countries even prohibited.

Nitroglycerin enters into the composition of a very important class of explosives, possessing the generic title of dynamite. A very large number of such exist under various fancy names, but for convenience they may be divided into three classes, namely:—

1. Dynamite in which nitroglycerin is alone the active principle; a chemically inactive material, such as kieselguhr, being used merely as an absorbent, as, for example, in ordinary dynamite No. 1.
2. Dynamite in which the absorbent used is, in itself, an explosive or combustible, such as, for example, “Atlas powder.” This class of dynamite is little used in this country.
3. Dynamite in which the liquid character of the nitroglycerin is destroyed by gelatinising it by means of gun-cotton, with or without the addition of oxidising agents.

The ordinary dynamite of commerce as used in this country is a mixture of 75 parts by weight of thoroughly purified nitroglycerin with 25 parts by weight of a porous infusorial earth known as kieselguhr, and consisting mainly of silica. In the case of kieselguhr dynamite, detonation is the more readily effected, and the combustion is more complete the more nearly the absorbing power of the kieselguhr is satisfied; but even then it is not perfect unless confined. Now, at present, no dynamite containing more than 75 per cent. of nitroglycerin is permitted in this country, and as the kieselguhr which is now generally employed has a greater absorbing power, it becomes necessary to reduce it by the addition of less absorbing materials, such as barytes, mica, tale, or ochre, in substitution for an equal amount by weight of kieselguhr.

Dynamite, as above described, is a soft plastic material, possessing a specific gravity of 1·4, varying in colour from light-yellow to yellowish red. It retains completely the properties of nitroglycerin while its tendency to explode, by slight concussions or blows, is diminished. It can be exploded under ordinary conditions by a detonator containing 5 grains of fulminate of mercury, or by heating to a temperature of 400° F., or by a sharp blow. When ignited by means of a fuse or match, it usually burns slowly away without exploding. When exposed for a short time to a temperature below 40° F. the nitroglycerin in the dynamite freezes and it becomes a hard solid mass. In this condition its sensitiveness to concussion is greatly diminished; but it is more liable to explode on simple ignition. Even a rifle bullet fired through it at a comparatively short distance fails to explode it, whereas a similar treatment would cause the detonation of the unfrozen material. The fact of dynamite freezing so readily is a fruitful source of accidents, occasioned more often by the reckless treatment it is subjected to with a view to restoring to it its plastic properties. Instances are on record of workmen placing frozen cartridges on the top of a fire or holding them on a shovel over a forge fire. Even when slowly thawed at a moderately increased temperature the greatest caution

* Full details of this accident are contained in a report (No. LXXXI., 1887), by Colonel Majendie, C.B., Her Majesty’s Chief Inspector of Explosives to the Secretary of State.

should be exercised in handling such cartridges. In actual contact with water for any length of time the nitroglycerin has a tendency to separate out, and it should therefore never be placed in wet blast holes unless properly protected. Accidents have occurred through neglect of such precautions, the nitroglycerin having percolated through crevices in the rock some distance from the seat of the charge.

Blasting gelatin is the characteristic type of class 3, and consists of—

Soluble guncotton, 7 per cent. to 8 per cent.

Nitroglycerin, 93 per cent. to 92 per cent.

It is prepared by adding a soluble guncotton to nitroglycerin. The latter dissolves the former and is converted into a pale yellow elastic gelatinous, semi-transparent mass. When ignited by a match it burns slowly with a yellow flame. When heated to 90°–95° F. it should not materially soften nor become moist or show any sign of exudation. At a temperature of 400° F. it explodes violently. Under ordinary conditions it is far less sensitive to concussion or blows than either of the ingredients of which it is composed. Its two constituents, each in themselves sensitive to ordinary means of detonation, become comparatively inert when united, owing to a change in their physical condition. When unconfined, a detonator containing 1 grm. of fulminate is insufficient to explode it. If, however, it be strongly confined so that the fulminate exerts its whole force, it explodes with a violence greater than that of nitroglycerin.

Blasting gelatin, like ordinary dynamite, freezes at 40° F. to a hard solid mass, and in this state, unlike dynamite, becomes more sensitive to concussion. A quantity of fulminate of mercury sufficient to detonate ordinary dynamite in the unfrozen condition will fail to detonate unfrozen blasting gelatin. The same quantity of fulminate, however, is sufficient to determine the explosion of frozen blasting gelatin, whereas it would be totally insufficient to explode frozen dynamite. Its behaviour is also the reverse of that of dynamite with regard to the impact of a bullet fired from a rifle. After long immersion in water, it becomes of a paler colour and opaque; but its explosive properties are unaffected. It is therefore specially adapted for submarine mining.

Two varieties of blasting gelatin have been recently introduced in this country, namely, gelatin dynamite, and gelignite. The first, as its name implies, ought to be placed midway between blasting gelatin and dynamite. It consists of a thin blasting gelatin mixed with other substances, such as cotton or wood meal, and contains about 80 per cent. nitroglycerin. The second variety contains the same ingredients as gelatin dynamite mixed with nitrate of potassium or other nitrate, and contains 60 per cent. of nitroglycerin. They are both very similar in appearance to blasting gelatin.

The invention and introduction of the blasting gelatin class of explosives marks a distinct advance in the history of modern high explosives, the importance of which is as yet but partially realised. The question of their stability has retarded their development, but when once removed it would appear that the problem so long confronting manufacturers of explosives would seem to be solved. Concentration of force in small compass, permanency, safety in use, and under ordinary conditions unaffected by immersion in water, all these properties seem to fulfil in a high degree the requisites of the ideal high explosive both for civil and military purposes.

Carbo-dynamite, the invention of Messrs. Borland and Reid, comes under the second of the dynamite class. The novel feature of this explosive consists in the use of a carbon, specially prepared, and capable of absorbing about nine times its own weight of nitroglycerin. The carbon employed for absorbing the nitroglycerin takes an active part in the explosion, and increases the energy over and above that which is due to the nitroglycerin contained in it. This arises from the fact that the nitroglycerin contains sufficient oxygen in excess to burn the carbon on detonation, leaving no residue. Two varieties of this explosive are manufactured, namely, No. 1 and No. 2.

Carbo-dynamite No. 1 is a soft plastic material possessing a specific gravity of 1.5. It consists of 90 parts by weight of thoroughly purified nitroglycerin, and 10 parts by weight of cork carbon. Like dynamite, it retains completely the properties of nitroglycerin, whilst the tendency to explode by slight concussion or blows is diminished. Unlike dynamite, however, it is not acted on by water even after long immersion, a property which makes it specially applicable for blasting in wet bore-holes. When detonated, it develops an energy about equal to that of blasting gelatin.

The No. 2 variety is very similar in appearance to No. 1, and consists of nitroglycerin, 50 per cent.; nitrate of potassium, 44 per cent.; carbon, 6 per cent. This variety develops an energy on detonation somewhat greater than that of dynamite No. 1.

Roburite, one of the latest additions to the list of explosives actually in use, consists of a mixture of nitrate of ammonium, dinitrobenzene, and chloronitrobenzene. The proportion of the chlorinated product is regulated so that 100 parts of the organic components shall not contain more than 4 per cent. of chlorine. It has a density rather less than that of water. Even when freshly made it requires a more powerful detonator to explode it than dynamite No. 1. When damp or slightly compressed it explodes with difficulty. It is non-sensitive to ordinary concussion or friction, and in contact with a flame ignites with difficulty. When heated it decomposes without exploding and burns with a smoky flame. These latter remarks hold good, at least, when small quantities are experimented with. On detonation, when strongly confined, it develops an energy comparable with dynamite No. 1. Although a "high explosive" it exerts on detonation more a rending effect—similar to gunpowder—than a shattering one. It has been used successfully for blasting coal and for quarrying.

"*Bellite*" and "*Securite*" are similar in composition to the above, in so far as their constituents consist of nitro-compounds of the aromatic series incorporated with oxidising agents, preferably nitrate of ammonium.

Favier's explosive which has, under the name of "Miners' safety explosive," been licensed in this country, consists of nitrate of ammonium and mono-nitronaphthalene, in the proportion of 91.5 of the former to 8.5 of the latter. The cartridges are made in the form of compressed hollow cylinders enclosed in waterproof wrappers. The central cavity is filled with a powerful explosive, such as dynamite or guncotton.

The few explosives which I have briefly referred to above, include all those of any importance which are in actual use for industrial purposes in this country.

The question "Which is the best explosive?" has often been put to me. It is like asking an engineer which is the best tool for drilling a hole. Every explosive has its special properties and no hard and fast rules can be laid down as regards the most economical application of explosives generally. A knowledge of the special properties of explosives enables one more or less to say which particular explosive is likely to be the most suitable for a particular class of work. To use a quick and powerful explosive for blasting coal would be as absurd as to use a diamond drill for boring holes through a deal board. The application of explosives to the best advantage is more a matter of judgment based on actual practical experience. Generally speaking one may say that for hard rock, especially in tunnelling, one would choose on economical grounds the most powerful class of explosives with a quick shattering action and of the highest possible density. For blasting coal or in quarrying marble or slate, and in all cases where the material operated on is required in large block, an explosive possessing a slow rending action is preferable.

The rapid development of the trade in modern high explosives has taken place under the controlling regulations of an Act of Parliament which came into force in 1875. That this Act was framed with considerable foresight in the interest of the trade and of public safety has been fully demonstrated by results. An examination of the reports made by Colonel Majendie, Her Majesty's Chief Inspector

of Explosives, and his colleagues, Colonel Ford and Major Cundill, to the Secretary of State, conveys a clear idea of the rapid growth of the explosives industry since 1875. The uniformly progressive increase in the number of factories and magazines, which naturally brings with it an increased employment of labour and an increased risk, has been accompanied by a steady decrease in the number of fatal accidents in manufacture and storage. During the years 1868-70 inclusive, when no sort of inspection existed, the annual fatalities amounted to 13 in number. The average fatalities for the four years preceding the Act were 37 in number, with 33 factories at work. There are now 112 factories in operation—many of them manufacturing new explosives—yet in 1888 only six fatal accidents are recorded, and of these three occurred in firework factories. The number of accidents recorded in the use of explosives do not show a diminishing tendency to the same extent, and for this the nitroglycerin class of explosives is chiefly responsible, but the result is not to be wondered at considering the increasing demand for these explosives. Further, it must be borne in mind that the use of explosives is not controlled by the provisions of the Act.

The average number of accidents in the use of gunpowder during the last 10 years is 28.4, causing 15.6 deaths, and injuries to 33.9 persons. The accidents in the use of dynamite and other nitroglycerin preparations during the last 10 years show an average of 18.4, causing 11.0 deaths, and injuring 21.4 persons.

1,120,800 lb. of dynamite were imported into this country in 1888 in 17 cargoes, showing a considerable increase over the quantity imported in 1887, and representing a value of between 50,000*l.* and 60,000*l.*, and Dr. Dupré reports that in no instance has he found it necessary to recommend the rejection of this foreign dynamite.

The conveyance of explosives by road is to a great extent controlled by local authorities, and the responsibility of enforcing the law practically rests with them. The transport of explosives on railways is still practically limited to gunpowder. This is much to be regretted, and in the interests of an important industry, and especially, as pointed out by Colonel Majendie, on grounds of public safety. In the annual report for 1887 he writes:—

"We regret to have to report that, notwithstanding repeated remonstrances, the railway companies have not yet seen fit to adopt a more liberal and reasonable policy with regard to the conveyance of dynamite and similar explosives. This subject has received attention in former reports, and in 1879 we made the following remark on the point:—

"This prohibitory policy, we desire emphatically to repeat, supplies a temptation to the surreptitious conveyance of the prohibited explosives which it is certain is not always resisted. As we stated last year, the practical effect is thus to introduce a greater risk than that against which the policy of the railway companies is professedly directed. If it is dangerous to carry dynamite openly in a properly constructed van by goods train, separated from all dangerous articles, and subject to the various precautions imposed by the byelaws, it must surely be more dangerous to convey it concealed, perhaps in unsuitable parcels, under the seats of smoking carriages, or among the miscellaneous baggage of a passenger train.

"The railway companies must know as well as we do that there is reason to believe that such surreptitious conveyance is deliberately practised on their lines, and upon what grounds they justify the continuance of a policy which tends directly to the encouragement of that practice, we are at a loss to imagine, unless, indeed, it could be supposed that the companies attach less importance to the possible (or under the present conditions we may perhaps say probable) occurrence of an accident than to the consideration that if any such accident were to occur the explosive which was being carried under their own regulations they would be responsible for damages."

"Again, in our 1879 Report, we said: 'The attention of the companies was formally called by the Board of Trade, at the instance of this Department, to the fact that this prohibitory policy supplies a temptation to the surreptitious conveyance of the prohibited explosives, which it is to be feared is not always resisted. The practical effect is thus to

introduce a greater risk than that against which the policy of the railway companies is professedly directed. If it is dangerous to carry dynamite openly in a properly constructed van by goods trains, separated from all dangerous articles, and subject to the various precautions imposed by the byelaws, it must surely be more dangerous to convey it concealed, perhaps in unsuitable packages, under the seats of smoking carriages or among the miscellaneous baggage of a passenger train. The information which we have received, although unfortunately not sufficiently definite to enable us to institute proceedings, leaves us in no doubt that such surreptitious conveyance is certainly sometimes practised, and that the practice is in some instances the direct outcome of the prohibitory railway policy above referred to.' To the opinion so expressed we decidedly adhere, confirmed therein by the experience of 1882, when Mr. F. H. Edwards, of Newcastle-on-Tyne, was convicted of taking 300 lb. of blasting gelatin with him, by passenger train (and partly in a smoking carriage) from Newcastle to Whitstable, and again in 1883, when John Payle was convicted of a similar offence, and again in 1884, when more than one such case was discovered.

"There is, we fear, too much reason to believe that these are merely instances which have accidentally come to light of a more or less considerable system of surreptitious conveyance of prohibited explosive, which the policy of the railway companies tends directly to encourage."

In France, Germany, and America all explosives are carried by railway companies under proper restrictions.

There is no doubt that the controlling provisions of the Act have appeared somewhat unnecessarily stringent to inventors and manufacturers in certain cases, but the manufacture and storage of explosives must always be accompanied by a certain amount of risk whatever the explosive may be, and obviously the Act must, to be effectual, deal on equal terms with explosives generally, without regard to individual claims to exemption from certain restrictions.

No country in the world possesses an Explosive Act so far-reaching and so efficiently carried out. On the other hand it may be said that no country can boast of such a high standard of manufacture, both as regards the purity and strength of its explosives.

DISCUSSION.

The CHAIRMAN said that the subject of Mr. Hake's paper was undoubtedly one of great and growing importance, and the thanks of the Society were due to him for his admirable résumé of it. Looking at the matter from the scientific side, and going back some 150 years, it was interesting to find that the phlogiston theory then held, although essentially a guess, came singularly near to the facts of modern thermo-chemistry. Being unsupported by quantitative knowledge it utterly failed, but it came very near the mark. The first effect of the advancement of Lavoisier's quantitative chemistry was to throw back a century the knowledge of thermo-chemistry, and seriously hinder progress in all questions bearing on endothermic and exothermic reactions. He could well remember how in the earlier days of Thomson's researches the subject was regarded as absolutely new. In that subject laid the germ of the whole question of explosives. He was very glad that Mr. Hake had called attention to Col. Majendie's important words concerning railway restrictions on the transport of high explosives. It was a common habit on the part of railway companies to practice what was, he thought, falsely alleged of those interesting birds who were said to hide their heads in the sand when danger threatened. It was no trifling matter for the public that in dealing with these dangerous bodies the action of railway managers was practically equivalent to saying to the manufacturers: "Do not tell us anything about it, but we will make such regulations that smuggling will be a necessity." He heartily wished that Col. Majendie had the power to carry his wise remarks into practice. It was just possible that the new Railway Rates Act might give a chance of obtaining some such power, and if so, he trusted that the opportunity would not be lost.

He concluded by inviting Dr. Dupré to give the meeting the benefit of his wide experience of the subject.

Dr. DUPRÉ said that he proposed to make a few remarks, but before doing so would be glad to hear the opinions of some of the practical members who were present. He was in a responsible and somewhat difficult position—a position which not infrequently caused him to be looked upon as a bugbear—and he desired to take this opportunity of dispelling some of the phantasies that seemed to exist in the brains of some inventors with respect to himself. He should therefore like to postpone his remarks until later in the discussion.

Nobody rising, Dr. DUPRÉ, continuing, said that he had listened to the paper with much interest, and it seemed to him that Mr. Hake need not have begun his paper in the modest manner he had done, as he had had a great amount of practical experience on the subject. As was well known to those present, no explosive was permitted to be manufactured in England until it had received the authorisation of the Home Office, and before that authorisation was given the explosive had to undergo a certain examination. But that examination was only imposed in the interests of the public safety, and there was no desire whatsoever on the part of the Home Office to interfere with an important industry, so long as that industry could be carried on without serious danger to the public. If inventors of explosives would but believe that, their feelings with respect to himself would, he thought, be considerably altered. He was often reproached with exercising severe restrictions under the present Act. But he wished to point out publicly, as he had often done to individual inventors, that he was acting under a law which had to be administered by the regular magistrates and judges. If any one infringed the Explosives Act, the Home Office had to prove their case in open court, and the offender was at liberty to call evidence to rebut that of the Home Office. In Germany, and he believed also in France, if an explosive was objected to, the authorities could simply enter the manufactory and order its destruction, without taking any steps to prove that it was dangerous. The position there reminded him strongly of the manner in which the Adulteration Act used to be carried out in Bavaria in the case of milk. The milk was brought to market in earthenware vessels, and it was the practice of the policeman charged with the duty to dip a steel rod into the milk, and to judge the quality of the milk by the character of the drops which ran down the rod on withdrawing it. If he thought the milk was not satisfactory, he simply opened his hand, down came the rod, and out went the bottom of the vessel, and the milk with it. In this country the authorities had not the power to take such summary measures, and therefore it was the more necessary that the initial examination of explosives should be carried out with extreme care. If this were not done, and an explosive proved objectionable, there would be great difficulty in stopping its manufacture. Mr. Hake had alluded in his paper to chlorate mixtures, and he might say that that class of explosives caused him very great trouble and anxiety. The diagram before them showed that no less than 67 chlorate mixture explosives had been invented, of which, not one, so far as he was aware, could be considered safe. They all broke down on one or two points. They were frequently chemically unstable, and they were all highly sensitive to combined friction and percussion. The Chairman might remember that in reference to some former remarks of his (Dr. Dupré's), he had spoken of broomsticks lying about in the Home Office. He confessed that he found a broomstick extremely useful for testing these explosives. Many of them which were said to be quite safe could be readily exploded by striking them with a broomstick on a deal floor. It should be remembered that explosives had often to be rammed into a bore-hole by means of a wooden rod; and even an iron rod was sometimes used. In doing this, a careless workman would often give just that slanting or glancing blow which was especially dangerous with chlorate mixtures. During the three first months of the present year, four lives had been lost, and a number of men seriously injured by explosions resulting from this practice. This point was therefore of great importance; and if any manufacturers or inventors were

present, he would say to them: do not bring forward any explosive for practical use until you have tested it with a penny broomstick—an apparatus as effective as it was simple.

Dr. GUSTAV BISCHOF wished to call further attention to the point raised by Mr. Hake as to the carriage of dynamite, &c. on railways. It would be in the memory of many present that in 1871 there was a general inquiry by the English railway companies into that subject. Being appointed the expert of the North British Railway Co. for the purposes of that inquiry, he had made a number of experiments. The result of one of them had puzzled him very much at the time, and he would refer to it now in the hope that some one might suggest a better explanation for it than he had been able to find himself. Among the questions which he had endeavoured to solve was the following: "Supposing a train laden with dynamite breaks down, or by any other means a number of cases of dynamite are scattered on the line, and another train runs into the *débris*, what will be the effect?" Mr. Nobel being willing to supply him with any quantity of dynamite, and the North British Railway Co. having placed an engine at his disposal, he had all the means for making an experiment on the point. He did so, and found that when he placed a quantity of dynamite on the rails, and laid a train of the explosive to a mass of dynamite scattered about near the rails, only the portions actually on the rails were exploded by the engine. He had referred to this experiment at the dinner given at the opening of Mr. Nobel's works near Glasgow, and the chairman of one of the railway companies who was present seemed to doubt it, remarking in his speech that he would have liked to witness the experiment. It was therefore privately arranged between the speaker and Mr. Nobel that this opportunity should be afforded on the return journey. Small portions of dynamite were accordingly scattered on the rails, and connected with larger quantities placed near by as before. The special train started on its return journey, the driver having been previously warned that there would be some slight detonations, of which he was to take no notice, but that he was to stop the train when they ceased. The train passed over the dynamite, and in an instant a head appeared in every window. He (Dr. Bischof) then addressed the visitors and said that a wish had been expressed to see this experiment, which he had endeavoured to gratify. Nothing remained but to prove that the explosions had not spread to the larger masses, and this he did by applying a fuse to the larger quantities of dynamite, which blazed up, showing that they had not been exploded. He had never been able to quite satisfy himself as to why the explosion did not spread, for one would expect such a detonation to have the same effect, as for instance, that by an ordinary detonating cap. He would be glad if any one experienced in the matter could suggest a reason for the peculiar action on this occasion.

Dr. DUPRÉ said that the difficulty mentioned by Dr. Bischof had occurred to others, and experiments such as that carried out by Dr. Bischof were a source of great trouble in dealing with dynamite and similar explosives. It was a characteristic of this class of explosives that when struck as a rule only that small portion which received the blow exploded. But there was no rule without an exception; and the exceptions to that particular rule were unfortunately numerous. Happily for Mr. Bischof's experiment it accidentally happened that no accident occurred; but it might just as likely have resulted in the explosion of the whole of the dynamite. As a rule that was what would happen, but occasionally it would not; and the exceptions were probably due to slight differences of temperature. For example, if gun-cotton was struck at the ordinary temperature, the explosion would be nearly always confined to the spot struck; but if struck at 80° or 90° the explosion would almost invariably spread. Dynamite could be safely fired at with a rifle at ordinary or low temperatures; but if fired at at summer temperature it would explode with very great violence. It was this characteristic of these explosives that led inventors with an insufficient amount of experience to claim for them that they would not go off by concussion, or that if they should,

it would only be the portion actually struck. That might hold good for a hundred times, and yet on the hundred and first time it might all explode. It was so with dynamite, and it was so with gun-cotton and analogous explosives. Gun-cotton might, for instance, be ignited in a 3-inch deal box and it would burn safely; but put it into a 3-inch box and there would probably be a dangerous explosion, so slight was the margin between danger and safety. Explosives were after all meant to explode, and it seemed to him, to say the least, unwise, when life and property were at stake, to rely too much on their assumed non-explosive character.

Mr. T. TYLER wished to remind members, especially those who had not been able to attend the general meeting at Glasgow last year, that in the Journal of the Society for July 1888 they would find a full account of the interesting experiments carried out at Messrs. Nobel's works during the visit of the Society. In that account would be found ample evidence of the statements now made by Mr. Bischof and Dr. Dupré. He referred to that because he knew of no series of similar experiments, the recapitulation of which to those who did not witness them so conclusively demonstrated the element of uncertainty referred to by Dr. Dupré. On the other hand, those who were present would well remember the almost extreme indifference with which they had seen dynamite handled on that occasion, thus justifying the observations of Dr. Bischof.

The CHAIRMAN, in proposing the usual vote of thanks to the author of the paper, said that he desired also to thank Dr. Dupré for his interesting remarks. He thought that it was of great advantage that one in Dr. Dupré's position should be able to give so lucid an explanation of his status. It was, of course, a great safeguard that no one holding a post of such authority was allowed to act except through the magistrates; though that was sometimes not an unimproved advantage, as the magistrates were often fundamentally ignorant of the subject. It was, for instance, somewhat perplexing when a magistrate showed such ignorance of the fundamental principles of science as to refuse to believe that it was possible to boil a substance without putting fire under it. Nevertheless, it was highly essential that every precaution should be observed, and that a clear case should be made out to an unbiassed mind before any serious action was taken. He would remind the members that most of them had for years regarded picric acid as a harmless substance, but they had all probably looked round their shelves with interest when it was discovered that it had bad habits at times. That was an example of how a substance might be handled for years without accident, and yet possess the possibilities of frightfully explosive power. It was just to guard against a great manufactory being set up on the strength of the supposed harmlessness of substances which might afterwards develop dangerous properties, that the Home Office was invested with its present powers. That office had, he considered, shown marvellous foresight and practical wisdom in the exercise of its functions, and if only similar thoughtfulness were shown by those who actually use explosives, there would have been far fewer accidents in mines and other places where high explosives were used. But, notwithstanding all the care of the authorities, men would use steel rods to ram cartridges into bore-holes, and thaw nitro-glycerin by direct heat from a fire; and while they continued those habits it would be impossible to prevent fatal explosions altogether.

Meeting held Tuesday, May 7th, 1889.

DR. BAILEY IN THE CHAIR.

ON THE HEAT-PRODUCING POWERS OF TWELVE SAMPLES OF COAL DETERMINED BY BURNING IN OXYGEN (IN THE APPARATUS DEvised BY THE AUTHOR) COMPARED WITH THEIR THEORETICAL VALUES AS CALCULATED FROM THEIR CHEMICAL COMPOSITION.

BY WILLIAM THOMSON, F.R.S.E.

SOME time ago I read a paper before this Society giving a description of a simple apparatus I constructed for determining the heat produced by the combustion of coal in oxygen (this Journal, 1886, 581—584). I then promised to give a further paper on the comparison of the chemical composition of a number of different coals, with their heat-producing powers. I selected 12 samples as follows for these experiments:—

1. Coal from Nixon's Navigation Collieries, Glamorgan.
2. Thackerley Collieries, Tyldesley.
3. Tyldesley Coal Co.
4. (Scotch coal), Drumgray, near Glasgow, bottom of seam.
5. (Scotch coal), Drumgray, near Glasgow, "mid-rib" of seam.
6. (Scotch coal), Drumgray, near Glasgow, top of seam.
7. Bickershaw Main.
8. Pemberton 5 ft.
9. Crombourne.
10. Wigan 4 ft.
11. Bickershaw 7 ft.
12. Pendleton 4 ft. (Andrew Knowles & Co's., Limited).

Supplied by Edward Storey and Co., of Liverpool.

The only modifications in the apparatus originally employed are, first, that a small glass tube is fused on at right angles to the tube at the top of the glass bell which receives the oxygen delivery tube, and on which is attached a piece of india-rubber tube closed by a spring clip, so that the water in the calorimeter may be allowed to enter and completely fill the bell and come in contact with the apparatus without rendering it necessary to withdraw the copper oxygen delivery tube. When the combustion is finished, the glass bell is drawn to the surface of the water, the clip removed and slipped on to the projecting glass tube, and the bell, with its wire gauze rings, moved up and down to thoroughly mix the water and remove the heat from any part of the interior of the apparatus. The second modification is the fixing of the bottom rim of the bell to a brass collar by means of plaster of Paris, this rim being made to fit in the stand carrying

the platinum crucible and coal, by a bayonet joint, which can be rapidly fixed by merely placing the bell on the stand and twisting it round.

The third modification is the determination by direct experiment of the specific heat value (in terms of water) of the whole apparatus which comes in contact with the water. For this purpose, 2,000 grms. of water are heated in one vessel to about 10° above the atmospheric temperature, and the whole then rapidly poured into the calorimeter, at the temperature of the atmosphere, the bell apparatus, in which the combustion is made, being left in the large beaker, and arranged at first so that no water can enter. The loss of heat is taken after stirring for a few moments and then opening the clip to allow the water to enter the bell, after the manner of actually working the apparatus. The specific heat of the part of the apparatus which actually comes in contact with the water as it is used in making the experiment may thus be determined. It is necessary to have the flask or other vessel which holds the warm water as nearly as possible 2,000 cc. capacity, so that no heat may be lost by coming into contact with any portion of cold glass in the act of pouring. To find the amount of water to which the apparatus is equivalent, assume that *one-half* of the difference between the temperature of the 2,000 grms. of water and that of the air is equivalent to 2,000 grms. of water, and calculate the result by proportion. Thus, if the atmospheric temperature in the dry calorimeter be 60° F., and the water poured into it 68°, then, after mixing, if the temperature stand at 67·2°, the equivalent of water would be—

$$\frac{2,000 (68 - 67 \cdot 2)}{68 - 60} = 400 \text{ cc. of water,}$$

so that it would be assumed that 2,400 grms. of water are heated in the calorimeter instead of 2,000.

The analyses of the coals were made as follows:—

The volatile matter and coke were determined by heating about 150 grains in a platinum crucible with a well-fitting lid till all volatile matter had been driven off. The ash was determined by burning in a muffle furnace about 25 grains.

The sulphur was estimated by heating 50 grains of the coal with twice its weight of pure sodium bicarbonate till it was almost all burned away. The mass was then fused, and a little potassium nitrate added to ensure the complete conversion of the sulphur into sulphate. The filtered water solution of the fused mass was then precipitated with barium chloride in presence of free hydrochloric acid.

The nitrogen was determined by heating 50 grains of the coal in fine powder with soda lime in a tube in the combustion furnace, and passing the vapours into standard acid.

The carbon and hydrogen were determined by taking about 5 grains of the coal previously dried in an air-bath at 105° to 110° C. for one hour. By this means the moisture was estimated, and the coal so dried was then transferred to a porcelain boat, and burned, first with dry air free from carbon dioxide, and then with dry oxygen free from carbon dioxide, the gases being passed through red hot oxide of copper, and then through lead chromate to the calcium chloride tube and potash bulbs.

The comparisons for heating power deduced from the chemical composition given in the accompanying table are calculated by assuming that all the carbon found would yield on combustion 8,080 Centigrade units of heat. The oxygen present was assumed to be in combination with the hydrogen, as in water, so that an equivalent of hydrogen calculated from the oxygen present was deducted from the total hydrogen, and the difference in hydrogen calculated as giving 34,462 units of heat. The sulphur also which burned away was calculated as giving 2,220 units, whilst the nitrogen was not taken into consideration.

The following is the order in which the different samples stand, the figures on the left showing the order of value as obtained by direct experiment, the figures on the right giving the order of value as determined by calculation from the chemical composition.

Mr. Scheurer-Kestner has lately published a number of similar analyses of a very interesting nature, but his results differ from mine in that all his figures obtained by experiment are higher than those obtained by calculation from the chemical composition. In my results the calculated figures in seven out of the 12 for calorimetric value are higher than the figures obtained by experiment, two are practically the same and three are lower.

I have to thank my assistant, Mr. J. Porter Shenton, for the very careful manner in which he made the analyses and experiments given in this paper.

DISCUSSION.

The CHAIRMAN did not understand what was meant to be the force of Mr. Thomson's remark, that in the case of one coal the result was higher than that obtained from burning pure carbon, because after all there was nothing to be astonished at in such a result. They knew that the heat of combustion of hydrogen was 34,000 calories as against 8,000 in the case of carbon, and there was no reason why the heat combustion of a particular coal composed of carbon and hydrogen should not be higher than a given amount of carbon if it were low in ash. He should like to ask Mr. Thomson in what way the coal was dried, because it was a matter of importance and there were one or two precautions which were frequently overlooked. At the time when this calorimeter was first brought before the Society, Mr. Thomson had promised to give further particulars as to determinations made upon coals which would add to the value of the paper. For his own part he never supposed that Mr. Thomson could expect more than very

approximate results from such an apparatus. Some had been very careful in the matter of their calorimeter, but had erred in not exercising sufficient care in the selection and examination of the coals chosen for experiment. Mr. Thomson, on the contrary, seemed to expect too much from his calorimeter, because whatever the calorimeter is calculated to do they could not expect accurate results from such an instrument. It might give comparable results, and these might be extremely valuable from a commercial point of view; but when it was sought to approach, as Mr. Thomson seemed inclined to do, a question of great scientific importance which had been already most carefully worked at, it was questionable whether any advantage was gained. It appeared to him that the problem which wanted solving was how to exercise more care in regard to the selection of the coals so as to admit of generalisation being deduced. To see, for instance, that they showed as far as possible similar physical characters and were not unlike with regard to their volatile constituents and ash. If a few samples of coals were examined in various ways experimentally they might learn some valuable facts. Mr. Thomson assumed that the whole of the moisture was condensed in the calorimeter. This he doubted. Whether all the allowances referred to were small or not they must affect the correctness of the results in a degree which could not be overlooked in measurements of calorific power of coal. Mr. Thomson had stated that the drying of the finely powdered coal was continued several hours till the weight was constant. His own experience was that the coal under these circumstances lost weight continually, first by giving up moisture and then by oxidation of the coal, and it was a matter in which some judgment was required as to when the moisture had been

driven off. Finely divided coal was known to oxidise even at temperatures below 100°C ., and he was acquainted with a case where it had even fired when a thin layer of dry coal was exposed to a temperature not exceeding 150°C .

Mr. Wm. Thomson, in reply, said he had gone into the question of the amount of heat carried off by the oxygen used in the combustion, and had found it to be so small that it was within the range of experimental error. He found it best to commence the experiment with all the apparatus at exactly the same temperature as the atmosphere.

It had been suggested that experiments should be commenced with the temperature a few degrees below the atmospheric temperature, but to get all the appliances, gas, and water to any temperature higher or lower than the normal, was a matter of great difficulty. Such a temperature would be liable to variation between the time when read off and when the experiment was made. He allowed everything to stand for a day, so that the apparatus, oxygen and water employed were all at the temperature of the atmosphere.

The amount of heat abstracted by the 2,000 grms. of water employed for the combustion of 1 gm. of coal amounted only to about 7°F . They had, therefore, the difference between the temperature of the air and the amount of gas, which varied from about $\frac{1}{3}$ to $\frac{1}{2}$ cubic foot. Now, if they took, for instance, the specific heat of oxygen or carbon dioxide, and the amount of gas required for the experiment as compared with the specific heat and quantity of water used, the error thus introduced was so small that for ordinary work it might be disregarded, as it lay within experimental error when the experiment was made without extraordinary precautions. As to the water converted into vapour by the change in temperature of the gas during the experiment, the difference between the amount of moisture in solution in the oxygen before the experiment and afterwards was so small that it might also for ordinary purposes be disregarded. As a test of the efficiency of this apparatus, he determined the heat produced by the combustion of purified charcoal, and found that it gave the figure obtained by Favre and Silbermann within 8 per cent. There was, however, one point which was necessary to observe, and that was the loss of heat from radiation. The heat gradually rose one degree per minute for the seven minutes during which the experiment lasted; then he left the apparatus to cool for seven minutes more, and he found it sufficiently accurate to divide the loss by two, and add that to the temperature obtained by the thermometer. This error might be much more accurately determined, but for ordinary practical purposes greater refinement is unnecessary. He thought the Chairman's suggestion to get two coals of different composition, but with the constituents built up chemically in the same manner, would be quite impossible. He had studied the question of error produced by the water taken up by the oxygen or burned gases during the experiment, but as the total quantity of water contained in $\frac{1}{3}$ to $\frac{1}{2}$ a cubic foot of gas at the ordinary temperature of the atmosphere was very small, and the amount due to the rise of 7° above the atmospheric temperature still smaller, the heat thus lost as latent heat might also for ordinary purposes be disregarded. It sometimes happened that when the oxygen was turned on too rapidly, or for some other reason some free carbon was liberated, the experiment might be regarded as spoiled; but when two experiments on the same coal were carried out satisfactorily, the results were the same, as nearly as the readings of the thermometer could be made. The thermometer he employed had a large bulb, and the readings could be made to about $\frac{1}{100}$ th of a degree F . The samples of coal used in his experiments were dried at 212°F . He suspected, like the Chairman, that the estimation of water by this method was unsatisfactory; but even Scheurer-Kestner worked this way, and he found that he soon reached a point when the coal ceased to lose weight. The Chairman mentioned the spontaneous ignition of coal dust at a temperature of 150°F . He must confess he could not understand this unless steam or moisture came in contact with it, and induced the oxidation of some finely-divided iron pyrites from which coal is never absolutely free.

A CORRECTION.

IN Dr. Weir's reply on page 448 of the June issue, he is incorrectly reported to have said that the Chinaman preferred to smoke opium containing little or no morphia because, if not used to excess, it would do him no harm. Dr. Weir wishes it to be stated that his meaning was misapprehended; and that what he did say was that the Chinaman preferred an opium which, as it happened, contained a much smaller percentage of morphia than the opium produced in, say, Asia Minor, because he found that he could obtain from such opium a greater percentage of *smokable extract* than from other kinds of opium richer in morphia.

Obituaries.

JOHN DALE, F.C.S.

JOHN DALE was born in Birmingham on the 11th of May 1815. He was educated in Birmingham and Warwick. In the latter town was an excellent schoolmaster, under whose care the subject of this sketch was placed, and to whose original and attractive mode of teaching Dale attributed much of the acuteness and power of observation subsequently developed in him.

This teacher was accustomed to take his pupils out walking, and to ask them questions on all natural objects that they came across, supplying them meanwhile judiciously from his own large fund of general information.

His school days at an end, John Dale went to Denbigh and was apprenticed to a chemist and druggist. Later on he removed to Rhyl, where he had access to a number of chemical and pharmaceutical books, and no doubt in the prosecution of his studies, all his spare moments were occupied.

He next proceeded to Manchester, and there acted as assistant to a Mr. Ansell, a chemist and druggist, a member of the Society of Friends, who was also an acquaintance of the renowned John Dalton. This was in the period between the years 1833 and 1835. (Ansell at that time was the only dealer in chemical apparatus to be found in Lancashire and Cheshire.) Under the circumstances it was only to be expected that Dale would soon make the acquaintance of

Dalton. That acquaintance once made, it soon ripened into friendship, for John Dale became Dalton's pupil. It was, moreover, but a foregone conclusion that so apt a pupil would be fired with the enthusiasm and genius of such a master, and indeed Dale not long after this commenced a course of lecturing on chemistry in all the principal towns of Lancashire. He received from Dalton especial commendation and, indeed, compliment on his skilful and original lecture-experimenting.

There now followed another slight change in a temporary removal to Altrincham. This, however, was soon succeeded by the return to Manchester, where a shop was taken in St. Mary's Gate, and it was during this period that Dale made the acquaintance of Mr. Thomas Roberts, with whom, some years later on, he entered into partnership. In the interim he became manager of a calico print works in Ardwick, and continued his duties in that capacity up to the year 1852, when he went to Cornbrook and started with Mr. Roberts the chemical works, which under his directorship became famous, and made widespread the name of the firm of Roberts, Dale, and Co. But previous to the entry of John Dale, these works had been occupied in the manufacturing of dyewood extracts, British gum, and wood spirit, and in the Exhibition of 1851, specimens of ultramarine manufactured by Kurtz were exhibited. It is noteworthy that after the formation of the new firm, numerous new methods of manufacture were introduced in place of older processes. This brings us to about the year 1854, when the staple trade of the firm was wood extracts and British gum. About this period the paperhanging trade began to develop, and the only colours then available were such as could be got at the oil and colourman's shop, such as *Venetian red*, *Verdigris*, *Bremen blue*, &c. Dale now introduced a much finer variety of colours; amongst them a much superior class of chrome yellows, and he gave a great impetus to the trade by introducing his lakes made from wood extracts. Shortly after, the manufacture of oxalic acid from sawdust by heating to fusion this material with the mixed alkalis, potash and soda, was commenced at the Warrington works, which later on was managed by Dale's eldest son, John. It was in accordance with a new process devised in Dale's laboratory and patented in 1856. The working of the new process, which marked a very important epoch in chemical industry, was undertaken in conjunction with J. D. Pritchard, and subsequently brought to further perfection by Dale, and carried on until such time as potash became sufficiently cheap to justify its sole use. Those who recollect the reports issued at that time of this process, will remember that the mode of separating the alkaline salts was based on the fact that whilst the potash salt was soluble the soda salt was insoluble in water. It is exceedingly probable that in connexion with the operations of this process, vacuum filtration on an industrial scale was employed for the first time; such an accelerated method of filtration being, of course, highly desirable in connexion with the separation of the oxalic acid solutions from gypsum, when the calcium oxalate obtained by causticising the insoluble oxalate of soda with boiling milk of lime, came to be treated with sulphuric acid. No doubt John Dale was perfectly aware of Gay Lussac's reaction discovered in 1829, by which carbohydrates and celluloses fused with potash yield oxalic acid. But he founded upon it the successful commercial process referred to. Just about this period, too, the manufacture of "solid caustic soda" was commenced and successfully prosecuted. The record now brings us to the year 1858, when Perkin discovered mauve, which he prepared from commercial aniline, using as his oxidising agent potassium bichromate. In conjunction with Caro, who was engaged as chemist about the years 1860 to 1861, Dale now endeavoured to find an equally effective oxidising agent to bichrome for preparing mauve, and at length it was discovered that copper sulphate, in conjunction with alkaline chlorides, answered the purpose; but to Dale's discernment was due the further and most important refinement of the process, involved in the judicious addition of a moderate amount of alkali. In fact, the obtainment of the desired yield of colour depended upon this collateral neutralisation with alkali. A distinct advantage was obtained in that, along with a good yield

of mauve, a black pigment was also produced, easily separated from the violet colouring matter and possessing a special value of its own. The formation of this black colour is all the more interesting inasmuch as it may be said to have led to the discovery of aniline-black by Lightfoot, to whom the reaction had become known.

In the meantime, C. A. Martins had been engaged as chemist at the Warrington works, and came there from Hofmann, in whose laboratory he had acquired a sound theoretical knowledge of the then recently discovered aromatic bases such as phenylene diamine, dimethylaniline, &c. He was at once set to work by Dale with the object of preparing new colours from such aromatic bases, through the medium of nitrous acid obtained from nitrite of soda.

From this course of experiments directly sprang the manufacture of Manchester brown ("Bismarck brown"), and Manchester yellow ("Martins yellow").

The patent for the Manchester yellow was taken out in the joint names of Dale, Caro and Martins (Eng. Pat. 2785 of 1864). Ordinary Aniline yellow or amido-azobenzene ("Fast yellow") was next placed in the market. The induline group, so named in the patent taken out by Dale and Caro (Eng. Pat. 3307 of 1863) was discovered about this period. Somewhat before this date, John Dale had commenced the manufacture of picric acid, first from Australian gum, and later on more advantageously from commercial carbolic acid.

Then followed the manufacture of aurin, which was also commenced about this period. John Dale's youngest son, R. S. Dale, was now set to work by his father upon the aurin process, which he completed, and in conjunction with Schorlemmer, wrought out the theoretical development of the subject, and with Schorlemmer succeeded in converting aurin into pararosaniline, thus establishing it as a triphenylmethane derivative (this Journal, 1885, 476). Further aniline colours were later on prepared in Dale's laboratory, and afterwards manufactured in the works. Among the names of those noted chemists who were engaged in Dale's laboratory were those of Caro, Martins, Schad, Leonhardt, and Koepf.

There were some novel and original processes devised and carried out during this period of great activity, which it may be interesting to notice. First and foremost amongst these was the use of the caustic soda and potash boiler, in which the evaporated water was utilised as steam, and consequently the fuel used in the evaporation was rendered more efficient, the steam being used for driving engines, whilst by the aid of this steam under pressure, the concentrated caustic liquors were at length, or when desired, forced over into a caustic pot, and there finished in the usual way. This method of working was modified later on, to the still greater economy of fuel, by the addition of vacuum apparatus, at the suggestion of Dale's youngest son.

A similar process and apparatus were subsequently used for the boiling down and recovery of esparto liquors by R. S. Dale.

But not only was the mind of Dale fertile and resourceful as regards manufacturing methods, but his ardent study of the pure science now stood him in good stead as regards analytical and valuation methods, and it is a fact that he mainly devised his own analytical processes. For example, the method for estimating tin with potassium bichromate was his, as was also that for determining indigo by reduction with copperas and lime, a vessel of water being connected with the closed vessel containing the reducing solution. As soon as the reduction was perfect (a siphon tube with tap connecting water vessel and reduced indigo solution) the tap was opened, and the volume of water sucked in corresponding to that of the oxygen absorbed, gave the data for calculating the weight of indigo present in the sample. It is believed that this method is now published for the first time. Another remarkably ingenious process was that devised by Dale as a rapid means of estimating in a quantity of the mixed alkalis, potash and soda, the amount of either. Each estimation only occupied half an hour. It was a volumetric method and was accurate

to half a per cent. Standard solutions of potash and soda were prepared. The mixture of the alkalis was taken and to it was first added a solution of tartaric acid to the point of neutralisation, and then just as much again for the production of bitartrate. The bitartrate of potassium being insoluble in a solution of bitartrate of soda of about 6° Tw., was fully precipitated. Filtration from the crystalline potassium salt now rapidly followed, and the precipitate was lightly washed with water, and both filtrate and precipitate were then separately treated with the respective solutions of known strength of potash and soda, whereby was alkalimetrically determined the excess acidity due to the bitartrates, and hence the amounts of the alkalis themselves present. R. S. Dale then modified his father's process, so as to render it available for mixtures of the chlorides and sulphates of the mixed alkalis respectively. These may serve as a few examples of many ingenious and highly useful commercial assay methods devised by Dale. During the last four or five years Mr. Dale's health had been failing, but his interest in the later developments of all branches of chemical industry had never flagged in spite of this. His loss will be greatly felt in the business with the interests of which he has been so long intimately connected. Very few chemists connected with the papermaking, calico printing and textile industries failed to apply at one time or another to him for counsel and advice, and never failed to obtain the assistance they desired. He died May 31st, 1889, and thus another of those great lights of former days, which have contributed to render illustrious the name of the Literary and Philosophical Society of Manchester, is removed, and we may truly say that whilst Joule stands pre-eminent in physical research, and Dalton in chemical theory, that John Dale, Dalton's pupil, takes rank as a typical representative of the successful application of chemical science to chemical industry.—W. S.

GASTON PLANTÉ.

M. GASTON PLANTÉ commenced his scientific life as laboratory assistant to Ed. Becquerel. Later, he became chemist to the firm of Christoffe et Cie. The study of galvanic polarisation, commenced in the laboratory of Becquerel, led to the publication of a series of papers since issued in a collected form. These "*Recherches sur l'Electricité*" deal mainly with the development of storage batteries, with which the name of Planté must always be associated. He died at Paris, at the age of 55, on the 24th of May last. To the Academy of Sciences he has bequeathed a sum of money sufficient for the establishment of a prize of 3,000 francs, which will be awarded every second year to some distinguished French electrician. His house and large gardens at Bellevue, near Paris, he has left as a place of retreat for indigent *savants*.—W. W. H. G.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Improvements in Centrifugal Fluid Separating Machines. W. Bergh, London. Eng. Pat. 4698, March 27, 1888. 8d.

THE improvements described in this specification refer more particularly to the suspension of the separator drum and its

carrying spindle. The bottom of the spindle is fitted with a cone centre which runs on a hard bearing in an adjustable footstep carried on the bedplate of the machine; the usual method in such machines is to carry the entire weight of this revolving portion from the upper bearing by means of a collar or similar device. The friction due to the ordinary method is hence eliminated, and the machine is practically frictionless.—C. C. H.

Improvements in Means for Expelling Liquid from and Compressing Sludge and other Semi-Fluid or Plastic Substances. J. Price, London. Eng. Pat. 8491, June 9, 1888. 6d.

See under XVIII. B., page 563.

An Improved Method of Straining or Filtering Fluids, and Apparatus therefor. J. G. Lorrain, London. Eng. Pat. 9667, July 3, 1888. 6d.

IN Eng. Pat. 6813 of 1886 (this Journal, 1887, 501), the inventor described a form of filtering medium consisting of a number of spheres of elastic material resting on each other, the interstices between the points of contact of the spheres forming the filtering spaces. These could, of course, be rendered smaller and hence a finer degree of filtration secured by compressing the spheres so as to diminish the size of the spaces or interstices. In the present instance the patentee proposes to apply the same media to centrifugal machines. The higher the speed the greater the compression of the spheres and the finer the degree of filtration, and *vice versa*. The degree and rate of filtration is thus dependent entirely upon the speed of rotation.—C. C. H.

Improvements in or relating to Lids for Drums and other Vessels and for Holes in Sheet-Metal Articles. J. Johnson and R. G. Brook, St. Helens. Eng. Pat. 10,526, July 20, 1888. 8d.

THIS invention has for its special object the sealing of holes in vessels containing "caustic grease, oil," or other matter, but can be applied to fixing lids over holes in any description of sheet-iron vessel. The lid has three projections on its inner face, two of them being plain, and secured to the lid. The third is placed diametrically opposite to them, and is moveable in dovetailed guides, or cheeks secured to or made solid with the lid. This moveable projection (or button) can be moved externally, either by a bar or key working in a slot, or other means. In fixing the lid, it is placed over the hole, and the fixed projections being forced under the rim, the moveable projection is then shifted until it presses against the rim and secures the lid.—E. S.

Improvements in Apparatus for Evaporating, Concentrating, and Distilling Liquids. W. R. Watson and R. A. Robertson, Glasgow. Eng. Pat. 11,485, August 9, 1888. 1s. 3d.

THIS invention is for improved apparatus acting on the same principle as that described by Yaryan, Eng. Pats. 14,162, of 1886, and 213 of 1888 (this Journal, 1887, 39, and 1888, 313). The improvements consist principally in the arrangement of the pipes by constructing them in a manner to provide for both the entry and discharge of the liquid under treatment at the same end of the apparatus. This enables the sets of tubes or coils being fixed to the shell or casing at one end only, allowing the other end of the tubes to freely expand and contract. It also admits of the whole series of tubes being readily withdrawn, whilst it obviates the necessity of external pipe connexions between the several concentrating vessels. The improvements are applicable to single-effect as well as to multiple-effect apparatus. The specification is accompanied with five sheets of drawings.—B.

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	½d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " 2s. 4d.	1½d.
" 2s. 4d., " " 3s. 4d.	2d.

Improvements in Apparatus for Evaporating, Concentrating, and Distilling Liquids. W. R. Watson and R. A. Robertson, Glasgow. Eng. Pat. 17,809, December 6, 1888. 8d.

The inventors here propose another improvement in apparatus of this class, by using double tubes, one within the other, having a central and an annular passage between their sides. The liquid is led into the annulus and the heated vapour or steam through the centre part. The tubes are grouped in series, and both liquid and vapour pass through them in a constant stream regulated by slides and valves, and the operation may be completed in one or more series of tubes according as single or multiple effect is desired.—B.

Improvements in and relating to Ammonia Engines and to Apparatus Connected therewith. J. H. Campbell, New York, U.S.A. Eng. Pat. 3873, March 5, 1889. 8d.

Aqua ammonia is placed in a boiler to which heat is applied to liberate the ammonia gas held in solution by the water. The ammoniacal gas then passes to and operates the engine, and the exhaust gas re-saturates partially spent aqua ammonia (previously drawn from the boiler) before it is returned to the boiler. This saturation is effected by cooling the partially spent aqua ammonia and bringing it into contact with the exhaust ammonia gas or vapour which it absorbs, increasing the degree of saturation of the ammonia solution, which is then returned to the boiler for the repetition of the operation. The improvements comprised in this specification consist in the methods and apparatus (1) for fully re-saturating the weak ammoniacal solution used by diffusing it in the form of spray through the exhaust vapour from the cylinder. This is accomplished by subjecting it and the unabsorbed vapour to further steps of absorption, and in disseminating the heat set free at each step by means of a cooling fluid. (2) In drawing off any vapour in excess of saturation of the spraying fluid after the fluid has been used for absorbing the exhaust vapour, enforcing final absorption by pressure. (3) In controlling any excess of pressure in the boiler without wasting any of the ammonia contained in it. (4) Working a secondary engine in conjunction with the main engine, both using the same absorbing apparatus. (5) Lubricating the cylinder and valves of the steam chest by injecting ammonia-solution under "boiler pressure" from the boiler. (6) Preventing foreign matter from passing from the boiler to the absorbing jet by means of a suitable strainer in the connecting pipe. The patentee makes 16 claims.—E. S.

Improvements in Travelling Platforms, Beds, or Trucks for Kilns or Ovens for Drying, Burning, Baking, and similar Operations. J. C. Fellner and C. Ziegler, Boekenheim, Germany. Eng. Pat. 6938, April 25, 1889. 11d.

In this invention the difficulties attending the proper lubrication of the platform wheels, owing to the high temperature to which the lubricating material is exposed, are obviated by constructing the travelling platform in such a way that the friction of rollers is substituted for that of bearing-axes; while at the same time, the concussion of the separate sections is avoided, and the use of buffing apparatus is greatly reduced. For this purpose the travelling platform is carried on two sets of paired, flanged wheels and rollers of different diameters, fixed on the same axle, and arranged on an endless chain and running on rails. The smaller (or outer) set only runs on the railway, the larger (or inner set) merely supporting the travelling platform, each platform having rails on the under side corresponding to the gauge of the larger wheels, on which they rest. By duly proportioning the diameters of the two sets of wheels, the advance of the platform may be made to bear any desired proportion to that of the rollers. As all the sections of the platform necessarily move simultaneously, further arrangements are made for effecting their removal and introduction, from or to the kiln, independently of each other. Full details are shown in the three drawings attached to the specification. The inventions are protected by four claims.—E. S.

II.—FUEL, GAS, AND LIGHT.

A Rapid Method for the Examination of Fire-Places. G. Lange. Zeits. f. angew. Chem. 1889, 240—242.

F. FISCHER has made an examination of fire-places and of the methods for judging of their efficiency. Theoretically Fischer's method is most accurate, but in practice it entails too much work and requires too much time. Lange thinks that the same end can be obtained by a simple determination of the carbonic acid in the fire-gases and their temperature. Whatever the composition of the coal or coke used as fuel, 1 kilo. of carbon forms 1·854 cubic metres of carbonic acid at 0° C. and 760 mm. pressure. The determination of carbonic acid in the fire-gases shows the amount of oxygen and nitrogen mixed with it, or if n volume per cent. be the amount of carbonic acid, then $100 - n$ represents the volume per cent. of oxygen plus nitrogen, or—

$$\text{for 1 kilo. of carbon} = 1\cdot854 \frac{100 - n}{n} \text{ cubic metres of O and N.}$$

If t^1 = temperature of fire-gases; t = temperature of air; c = specific heat of 1 cubic metre of CO_2 (up to $150^\circ \text{C.} = 0\cdot41$, $150^\circ\text{--}200^\circ \text{C.} = 0\cdot43$, $200^\circ\text{--}250^\circ \text{C.} = 0\cdot44$, $250^\circ\text{--}300^\circ \text{C.} = 0\cdot45$, $300^\circ\text{--}350^\circ \text{C.} = 0\cdot46$); and c^1 = specific heat of 1 cubic metre of O or N (about 0·31), then the loss of heat in fire-gases for each kilo. of carbon burnt, expressed in calories, is $L \cdot H$ (loss of heat) = $1\cdot854 (t^1 - t) c + 1\cdot854 (t^1 - t) \frac{100 - n}{n} c^1$. The calorific value of 1 kilo. of carbon is equal to 8,080 calories, consequently the formula $\frac{L \cdot H}{8,080}$ indicates the percentage of loss of heat by the fire-gases. An example will best illustrate the mode of applying the formula. On examining the fire-gases from a small stove it was found, in the morning, that they contained 7·8 per cent. of CO_2 , and their temperature was 221°C. The temperature of the air was 6°C. In the afternoon the carbonic acid gradually decreased from 5·4 to 2·8 per cent. of CO_2 , on an average, to 3·7 per cent. of CO_2 , with a temperature of the gases at 178°C. , the temperature of the air being 8°C.

For the work of the morning the loss of heat amounted to:—

$$\begin{aligned} L \cdot H &= 1\cdot854 (221 - 6) \times 0\cdot43 + 1\cdot854 (221 - 6) \frac{100 - 7\cdot8}{7\cdot8} \times 0\cdot31 = 1,635 \text{ calories or percentage of} \\ L \cdot H &= \frac{100 \times 1,635}{8,080} = 20\cdot2 \text{ per cent.} \end{aligned}$$

For the work of the afternoon the loss of heat amounted to:—

$$\begin{aligned} L \cdot H &= 1\cdot854 (178 - 8) \times 0\cdot43 + 1\cdot854 (178 - 8) \frac{100 - 3\cdot7}{3\cdot7} \times 0\cdot31 = 2,676 \text{ calories or percentage of } L \cdot H = \\ &= \frac{100 \times 2,676}{8,080} = 33\cdot1 \text{ per cent.} \text{—S. H.} \end{aligned}$$

Firing with Liquid Fuel. L. Loew. Dingl. Polyt. J. 272, 364—375.

THE author points out that the employment of liquid fuel dates from the early ages (440 to 441 B.C.). It is only within comparatively recent years that any appreciable advance has been made in rendering it capable of taking the place of solid fuel, and for obvious reasons it is in America and Russia that the most favourable results have been obtained. Crude petroleum is unsuited for the purpose of fuel owing to its low flashing point. In the Caucasus the raw product is first exposed two or three days to a gentle heat, which removes the dangerous and more volatile portions of the oil. This is, moreover, advisable, since the thinner the oil the greater the amount of fuel used up for a given calorific effect; also the flame produced is very long.

Petroleum residues are very suitable for fuel, and are used almost exclusively for that purpose on steamers of the Caspian and Black Sea.

Residues from the distillation of lubricating oils, being very cheap, are employed as fuel, and the same applies to shale oil.

On the average 1 kilo. of petroleum can evaporate 13.75 kilos. of water when burnt under suitable conditions, whereas 1 kilo. of coal will only evaporate 7 kilos.

Experiments were further made with crude creosote, oil-gas, tar, and resinous products, with a view to determining their value as fuel. They all burn well when certain precautions are taken. Paraffin oil being too expensive for industrial purposes, was not included in the following experiments, which serve to show the relative amount of various fuels necessary to distil a certain quantity of oil. In this case the relative amounts of fuel consumed were:—

	Brown Coal.	Coal.	Crude Creosote.	Gas Tar.
	Kilos. 800	Kilos. 338	Kilos. 208	Kilos. 230
Costing	Marks. 3.6	Marks. 6.93	Marks. 5.96	Marks. 6.90

Resinous products from tar and oil are not advantageously burnt alone, since they fetch a better price as asphalt, &c.

The author describes the spray-apparatus employed in these trials, for the details of which the original paper must be referred to. It is stated that the evaporating power of liquid fuel is greater than with solid fuel.

Regarding the quantity of heat that can actually be utilised, this only amounts to 80 per cent. of that represented by the evaporating power, with solid fuel, 20 per cent. being lost. This is due to the loss of heat with solid fuel, being four times greater than with liquid fuel. Complete combustion of solid fuel is only attained at the cost of the developed heat, since the excess of air necessary exerts a cooling effect. On the other hand, with good spray firing of liquid fuel, no excess of air is required for complete combustion, and the chimney emits nothing but the products of combustion.

Again, the effective power of a boiler is far higher when heated with liquid rather than with solid fuel, the relative values being from 0.5—0.62 for the former to 0.8 for the latter. Formule are given for calculating the size of a spray-apparatus required for firing a boiler where the quantity of coal consumed by the same is known.—A. R.

Dowson Gas. E. Schilling. J. für Gasbeleucht., 1889, 424—432.

A NEW application of Dowson gas is its use in Schwabing to work a gas motor of 60 horse-power for the electric lighting of the streets. It is used in the gas industry under the name of "generator water-gas" for "half water-gas" for heating retort ovens.

The following are analyses of gases made by passing a current of air and aqueous vapour through a thick layer of red-hot carbonaceous matter:—

	1.	2.	3. Generator Water-Gas.		4.	5.	6.
	Munich Illuminating Gas.	Generator Gas from Coke.	(a.) Normal.	(b.) Excess of Water Vapour.	Dowson Gas.	Water-Gas.	A Mixture of 1 cb.m. Water-Gas and 1 cb.m. Generator Gas.
	Vol. proc.	Vol. proc.	Vol. proc.	Vol. proc.	Vol. proc.	Vol. proc.	Vol. proc.
Carbonic acid.....	1.6	1.5	8.8	11.2	6.0	2.7	2.2
Carbonic oxide.....	9.6	25.7	23.2	16.0	23.0	45.8	30.8
Hydrogen	49.6	Traces.	12.7	19.9	17.0	49.2	11.2
Marsh gas	30.7	2.0	0.3	..
Heavy hydrocarbons..	1.7
Nitrogen.....	3.8	69.8	55.3	49.9	52.0	1.0	55.8
	100.0	100.0	100.0	100.0	100.0	100.0	100.0

From the above analyses the equivalent of heat of these gases is easily calculated. The heat equivalents are given in the following table, and it must be noted that for the

hydrogen constituents the heat of combustion is calculated not as liquid water, but as aqueous vapour.

HEAT EQUIVALENT OF 1 CB.M.

	1.	2.	3. Generator Water-Gas.		4.	5.	6.
	Munich Illuminating Gas.	Generator Gas from Coke.	(a.) Normal.	(b.) Water-Gas Excess.	Dowson Gas.	Water-Gas.	Mixture of 1 cb.m. of Water-Gas and 4 cb.m. of Generator Gas.
	Cal.	Cal.	Cal.	Cal.	Cal.	Cal.	Cal.
Carbonic oxide.....	289	773	689	481	692	1,316	926
Hydrogen	1,316	..	337	528	451	1,305	297
Marsh gas	2,604	170	263	..
Heavy hydrocarbons..	1,170
Sum.....	5,379	773	1,026	1,009	1,313	2,884	1,223

From this table it is seen that Dowson gas has scarcely the fourth part of the heating power that illuminating gas has.

For the production of Dowson gas a small boiler with double walls is used and steam is generated continuously from it and superheated in the fire-box; this is introduced

at the same time with the necessary quantity of air for combustion under the grid of a generator. The generator shaft is filled with anthracite and is provided with a valve arrangement to prevent escape of gas when the fuel is added. The procedure is then like that for the preparation of water-gas. A part of the anthracite is first burnt to carbonic acid. The temperature must be sufficient to cause the reduction of this carbonic acid to carbonic oxide, as well as to decompose the water, thus forming hydrogen. The use of anthracite is necessary to produce a gas which by its condensation shall give the least possible amount of tarry matter. It is also necessary that the supply of air and vapour under the grid shall be as regular as possible. Coke cannot be used on account of the large quantity of ash it leaves. The generator has in its upper part an exit tube which is separated in two parts by a stop-cock arrangement. One is for the escape of the less valuable gas produced at first. The other leads the normal gas into a scrubber arrangement, which is divided into two parts. One in which the gas rises is filled with coke, over which runs a stream of water. The other contains dry coke. The gas goes from here into a receiver. One man is sufficient to work the little boiler, the generator, and the gas motor. The filling up of the generator shaft must be done regularly, since the regularity of composition of the gas is influenced by the height of the pile of combustible matter.

The Dowson gas apparatus is used in many places in Germany, while the water-gas apparatus has very limited application. The latter is produced first by passing air and then aqueous vapour through the generator; thus a mixture of generator and water-gas is formed which does not differ much in composition from Dowson gas, but the preparation of which is more complicated and expensive.

One disadvantage of Dowson gas is the large amount of carbonic oxide it contains, which amounts to about 23 per cent., almost $2\frac{1}{2}$ times as much as in illuminating gas, in consequence of which it is about three times as poisonous.

—A. J. S.

PATENTS.

Improvements in Apparatus for Making Gas. E. Brook and A. Wilson, Middlesbrough. Eng. Pat. 3949, October 12, 1876. (4th Edition.) 11d.

THE improved apparatus is a eupola-shaped furnace, either square or round in cross section, and which may be described as consisting, vertically, of two parts, viz., a cone-shaped retort above, and a combustion chamber below. This latter has a solid hearth upon which the ashes and clinkers accumulate. Air is blown (preferably with a steam injector) through a series of tuyeres a little above the hearth, and, at the level of the junction of the two vertical divisions of the apparatus, a series of lateral holes allow the escape of the gas produced to an annular space or channel surrounding the retort, whence it passes away to the point of consumption. It will be seen that by this arrangement the gas leaves the apparatus as soon as formed in the hot part of the furnace, and does not come into contact with the cool portion of the fuel, fresh supplies of which are introduced at the top of the generator by means of a suitable hopper. If preferred, the air blast may be introduced through a perforated channel in the solid hearth of the combustion chamber.—A. R. D.

Superheating Steam, and Making Heating and Illuminating Gas. B. Hunt, London. From T. S. C. Lowe, Morristown, U.S.A., and G. S. Dwight, Mount Clare, U.S.A. Eng. Pat. 173, Jan. 14, 1878. (2nd Edition.) 11d.

THROUGH a bed of fuel in a generator of the usual type hot air and superheated steam are blown alternately. While the former blast is on, the gaseous products evolved are taken to a chamber where they enter into combustion with a further supply of heated air here admitted, and whence they pass through a stack situated over the combustion chamber and packed with loose brickwork. Preferably two such stacks and chambers are attached to each generator. When the air blast has raised the fuel to incandescence, and the stacks

are also intensely hot, the air supply is cut off, and steam, superheated by traversing one of the stacks, is admitted in its place. The water-gas now produced is fixed by passing through the second heating stack, after leaving which its sensible heat may be utilised for steam raising or other purposes. When illuminating gas is required, petroleum or other suitable hydrocarbon is admitted at the top of the generator, where it becomes vaporised, and, mingling with the water-gas, is rendered permanent in the stack or fixing chamber. The specification is accompanied by three sheets of drawings.—A. R. D.

Improvements in the Generation of Water-Gas, and in Apparatus therefor. P. Jensen, London. From the European Water Gas Company, Stockholm, Sweden. Eng. Pat. 4907, November 9, 1881. (2nd Edition.) 8d.

ONE generator is used in connexion with two regenerators, which are in turn made intensely hot by the combustion therein of a portion of the water-gas produced in the process. While one regenerator is being thus heated, the other is being traversed by the steam supply, which is here so highly superheated that it is said to be already largely decomposed when it enters the generator, in the upper portion of which it meets a constant shower of coal dust automatically thrown in. After passing downward through the mass of fuel in the generator, one part of the issuing gas is conducted to the gasholder, while the other part goes to heat the regenerators as above mentioned. For the production of illuminating gas the addition of a suitable hydrocarbon is prescribed. The chief feature of this invention is that by operating as above described, and by making the regenerators sufficiently large, the production of water-gas is not intermittent but continuous, as the steam is so highly heated in the regenerators that the temperature of the fuel in the generator is never allowed to fall below the point most suitable for the required decomposition.—A. R. D.

Illuminating by Means of the Incandescence of Refractory Substances. W. H. Spence, London. From O. Fabnehjelm, Stockholm, Sweden. Eng. Pat. 5646, December 5, 1883. (2nd Edition.) 8d.

REFRACTORY oxides, such as those of magnesium, calcium, zirconium, and silicon (that of magnesium is generally preferable) are mixed, separately or together, with starch or gum so as to form a plastic mass. From this, wires, pins, or lamellae are formed by squeezing it through dies or by other suitable means, and are bent while still soft into any desired shape; they are then dried and strongly ignited. A number of them are fixed in a socket of iron or brass, preferably of U section, by inserting them in a mass of damp clay or magnesia filling the socket. The whole contrivance is termed a "comb." The sockets may be straight or curved, and provided with hooks or loops so that they may be attached to a support allowing them to hang in the flame which is to render the wires or pins incandescent. The whole is planned so that all parts may be readily replaced, as at the high temperature used the refractory material is slowly volatile. The socket may be dispensed with by making the wires or pins in the form of loops so as to hang on a simple metal wire or hook. The heating agent used is water-gas made in the ordinary way, and burnt from a common gas-burner, such as a fish-tail burner.

The patentee claims the manufacture of wires, pins, or lamellae from the above-mentioned refractory oxides, and the use of such oxides in such forms to produce light when heated by water-gas, "burning in the air at the ordinary pressure and under the ordinary conditions of the atmosphere."—B. B.

Improvements in the Method of Illuminating by Means of the Incandescence of Refractory Substances. O. Fabnehjelm, Stockholm, Sweden. Eng. Pat. 7573, June 22, 1885. (2nd Edition.) 11d.

THE patent is for improvements on the system of incandescent illumination set forth in Eng. Pat. 5646 of 1883 (preceding abstract), and refers especially to the construc-

tion and arrangement of the frames for carrying the material to be rendered incandescent. Thus needles of the refractory material (which may be magnesium, calcium, zirconium or silicon oxides, cyanite, kaolin, or quartz) may be made with one end thickened to form a head, so that they may be supported in a frame consisting of a perforated plate of metal, porcelain, or other suitable material. The frame or holder may be arched or made star-shaped, round, or polygonal, and the burner beneath it may be of similar design. Rods rising vertically from lugs at the side of the burner, and either straight or curved, serve to support the holder above the flame, and may be provided with a screw adjustment for raising and lowering it. In place of rods a glass chimney, cylindrical or bell-shaped, may be used, and the frame suspended from its upper end. For round or star-shaped burners a central rod may be employed. The burners are better made with a number of fine holes to allow the exit of the water-gas, rather than with annular or other slits, a more powerful light being thereby obtained.

For security in transit of such "incandescent pieces" or "combs" as are not best sent with their refractory needles, &c. separate from the frame, a special packing case with grooves to receive the "combs" is patented. (See also this Journal, 1886, 424.)—B. B.

Improvements in Purifying or Treating Coal Gas and other Gaseous or Liquid Products of Destructive Distillation, and in Part applicable in the Alkali Manufacture. A. Campbell, London, and W. Boyd, Glasgow. Eng. Pat. 10,186, July 13, 1888. 6d.

AFTER separating the tarry matter, the gas is passed through scrubbers down which is trickling water containing in suspension peroxide of manganese, which reduces the sulphuretted hydrogen and polysulphides to free sulphur. The manganese is re-oxidised and the ammoniacal liquor is either heated so as to drive off the ammonia and carbonic acid for the production of ammonium carbonate, or the gases may be passed into a solution of manganese sulphate, manganese carbonate being precipitated and ammonium sulphate produced. The manganese carbonate on ignition in air is converted into manganese peroxide. Or most of the carbonic acid is expelled and the residual ammoniacal liquor used for purifying more of the gas from carbonic acid; this may also be separated by passing the gas through a thin cream of black-ash waste, the sulphuretted hydrogen liberated being subsequently passed through the manganese scrubbers. The manganese is used over and over again until it contains a considerable proportion of free sulphur, when this is extracted by any suitable method. The fixed ammonium salt in the liquor from the tar condensers and also from the manganese scrubbers consists mainly of sulphocyanide, and this is obtained in the crystalline form by boiling down the liquor when sufficiently concentrated.—E. E. B.

Improvements in the Manufacture of Compressed Artificial Fuel. G. Frank, New York, U.S.A. Eng. Pat. 11,677, August 13, 1888. 6d.

ABOUT 50 parts by weight of coal dust or coal in a granular condition, and 40 of powdered calcined brick or similar earthy material, are mixed with 10 parts of tar or similar hydrocarbon matter, in a pug-mill heated by steam, pressed into moulds of any desired shape, allowed to cool and harden. For domestic use the sawdust of sandalwood or some other aromatic substance may be added, while for disinfecting purposes any suitable substances, "such substances being coffee beans, or anything possessing similar anti-septic and fragrant elements," may be employed.—B. B.

Improvements in Artificial Fuel. G. Frank, New York, U.S.A. Eng. Pat. 12,377, August 28, 1888. 6d.

NINETY-FIVE pounds of quicklime and 5 lb. of gypsum are mixed with 10 galls. of water, and added to a solution containing 2 lb. of lead acetate in 5 galls. of water; about 100 lb. of some carbonaceous substance, such as vegetable charcoal, coke or coal, in powder, is added to the mixture and incor-

porated by stirring. The pasty mass is then formed into blocks or cakes (which may be perforated) and dried.

It is claimed that the mineral ingredients cause the product to be coherent though porous, and improve its qualities as a fuel.—B. B.

Apparatus and Process for Manufacturing Gas. J. D. Averell, Brooklyn, U.S.A. Eng. Pat. 2914, February 19, 1889. 8d.

THE gas here referred to is to be made from wood and enriched with vaporised oil. The wood to be dealt with is placed in a metal cartridge case, having one end open. When filled the case is thrust into a retort with the open end to the rear. Steam introduced at the back of the retort softens and disintegrates the wood, thus aiding the distilling process. The gas here produced passes to a hydraulic main, where it is mixed with hydrocarbon vapours generated by distilling oil in a separate retort, preferably placed above the wood retorts.—A. R. D.

Improvements in the Method of and Apparatus for Converting Solid Fuel into Gaseous Fuel. W. J. Taylor, Chester, U.S.A. Eng. Pat. 4807, March 19, 1889. 8d.

THE main feature of this invention consists in maintaining a deep bed of ash below the incandescent fuel in the generator. Peep-holes are provided to enable this incombustible layer to be kept at a uniform level; and to facilitate the regular removal of ash and clinker, the base of the generator is made to rotate upon a central support.—A. R. D.

Improvements in the Trays or Grids of Gas-Purifying Apparatus. C. H. Turnbull, New Westminster, Canada. Eng. Pat. 5134, March 25, 1889. 6d.

THE tray consists of a number of strips of iron, wood, or other suitable material of elliptical cross section, kept parallel to and equidistant from each other by means of washers, through which pass tie-rods going from side to side of the tray. The strips are so placed that the longer axis of their elliptical cross section is at right angles to the plane of the tray.

By this arrangement any absorbent substance carried by the tray (e.g., lime for gas purification) presents a large surface to the gases it is intended to absorb; the tray is also stiffer than it would otherwise be. One of the uses to which it can be put is the removal of tar from gas by allowing the crude gas to stream through the requisite number of trays, placed one above the other, and kept wet by a stream of water from the top.—B. B.

Improvements in Apparatus for the Manufacture of Illuminating or Heating Gases. W. M. Cosh, Baltimore, U.S.A. Eng. Pat. 5181, March 26, 1889. 8d.

THE improved apparatus consists of a generator having on either side a firebrick superheater surmounting a combustion chamber. Each superheater is connected both to the upper and lower portions of the generator, communication being controlled by suitable valves. As will be seen, the apparatus may be used in a variety of ways, but the following *modus operandi* is preferred:—Steam is admitted at the top of the highly-heated superheaters, and after passing downwards through these, is caused to travel upward through the mass of incandescent fuel in the generator. When the lower portions of the fuel have fallen in temperature below the point suitable for decomposition, the course of the current is changed, and the superheated steam is caused to enter the generator at the top and pass downwards through the fuel. When the decomposition again begins to slacken, steam is turned off, and an air-blast is introduced at the bottom of the generator. The products of incomplete combustion passing to the combustion chambers of the superheaters, meet there a supplementary supply of air, find their way upwards through the brickwork, when the apparatus is again brought to the temperature necessary for the decomposition of steam. Means are provided for the introduction of naphthalene when an illuminating gas is required.

—A. R. D.

Improvements in the Manufacture of Artificial Fuel. A. J. Boulton, London. From H. G. Weber, Atlantic, U.S.A. Eng. Pat. 5389, March 29, 1889. *Id.*

COAL dust or waste coal is mixed with ground oil-cake, the resulting mass moulded into blocks, balls, or other suitable shape, and allowed to dry. The proportions depend on the nature and condition of the materials. It is claimed that the oil-cake serves to hold the particles of coal together, to facilitate their ignition, and to yield much heat from its own combustion.—B. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Occurrence of Paraffin in Crude Petroleum. E. A. Partridge. J. Franklin Inst. 1889, 479—484.

It is well known that the paraffin obtained by the distillation of petroleum residues is crystalline, while that obtained directly (as in the filtration of residuum) is amorphous. Ozokerite differs but slightly from paraffin, the main difference being want of crystalline structure in it as found crude. As crystalline paraffin could be obtained from ozokerite by distillation alone, it has been supposed to be engendered in the process. Recently, however, crystalline paraffin has been obtained from ozokerite by extraction with amyl alcohol, and in the same way, by repeated treatment of petroleum residues with amyl alcohol, a substance melting at 59° can be obtained which cannot be distinguished from ordinary paraffin. The action of amyl alcohol is probably the same as that effected by distillation, viz., a partial separation of colloid substance. These facts point to the conclusion that crystallisable paraffin exists ready formed in both petroleum and in ozokerite, but in both cases other colloidal substances prevent its crystallisation.—D. B.

PATENT.

Improvements in and Apparatus for the Distillation of Tar and the like. F. Lennard, East Greenwich, Eng. Pat. 7334, May 17, 1888. *Id.*

IN this invention the distillation is effected in a continuous manner, and it is claimed, more economically and efficiently than hitherto. The patentee causes the tar for distillation to pass in films or streams of small depth over surfaces heated by means of an oil-bath. To ensure the effectual working of the still, the tar, before entering, should be heated sufficiently, so that the distillation commences immediately the tar is admitted into the still. The volatile products are collected as they arise, and the pitch passes off at the outlet. Steam is injected into the still to facilitate the operation. For details of the apparatus and its mode of working, the specification and drawings must be consulted.

—D. B.

IV.—COLOURING MATTERS AND DYES.

The Separation of Certain Red Shades of Acid Violet into Acid Magenta and Acid Violet. R. Meldola. Dyer, 1889, 21—22.

ACID violets of a red shade are produced by the alkylation of acid magenta. The alkylation is, however, not complete, and the author has devised a process of separation which is as follows:—A known weight is dissolved in hot water, and after cooling, the colouring matter is precipitated by basic lead acetate and filtered, and the precipitate (A) repeatedly washed with cold water till the washings (B) are colourless.

The precipitate (A) is decomposed by ammonium carbonate, the lead carbonate filtered off, and the colouring matter in the filtrate estimated by evaporation and weighing the residue. The washings (B) are made acid with dilute sulphuric acid, then alkaline with lime, filtered to remove calcium sulphate and evaporated to dryness. The dry residue is treated repeatedly with hot alcohol, which extracts the lime salts of the violet colouring matters, leaving that of the acid magenta undissolved. The shade of the precipitate (A) and the two portions of the washings (B) can be ascertained by dye trials.

The author points out that it is necessary for dyers to remember that mixed colouring matters such as the above, if used in successive dyeing, are almost certain to give variations in the degree of redness and brilliancy.—R. L. W.

On some Derivatives of Resorcinoldisulphonic Acid. F. Uzer. Monatsh. 9, 1127—1131.

To prepare *nitrosoresorcinoldisulphonic acid*, 100 grms. of potassium resorcinoldisulphonate are dissolved in 400 cc. of water. The solution is acidulated with 15 cc. of glacial acetic acid, and 20 grms. of potassium nitrite are added. The mixture, which becomes dark violet, is poured, after some hours' standing at a moderate temperature, into ice water, when violet crystals of potassium nitrosoresorcinoldisulphonate separate, soluble in hot water, insoluble in alcohol, exploding on heating, and yielding precipitates with most metallic salts. On oxidation in alkaline solution with hydrogen peroxide or with a solution containing 2 per cent. of potassium permanganate, the nitroso-compound is converted into the nitro-compound. Its aqueous solution turns dark red on addition of ferric chloride. Treated with fuming nitric acid, styphic acid is formed. On boiling the nitrosoresorcinoldisulphonic acid with tin and hydrochloric acid, an amido-compound is formed; the yield is 80 per cent. of the theoretical one. On addition of nitrous acid to this body, the solution is first coloured green, turning into a greenish-yellow and into orange on concentration, the solution yielding, on cooling, orange crystals. It has not the properties of a diazo body, but seems to be an azo colouring matter.—A. L.

On an Easy Method for Preparing Leuco-Malachite Green. M. Nencki. Monatsh. 9, 1148—1149.

Forty grms. of benzaldehyde, 100 grms. of dimethylaniline, and 40 grms. of 93 per cent. alcohol, are heated on the water-bath in a flask with reversed condenser and holding about 2 litres. A small separating funnel connected with the flask contains 65 grms. of phosphorus oxychloride which are allowed to run gradually into the mixture in the flask. The violent reaction is moderated by shaking the contents of the flask. After adding the phosphorus oxychloride the reaction is completed by heating for about half an hour on the water-bath, or until bubbles cease to rise to the surface. The mixture is dissolved in hot water, and an excess of caustic soda added after cooling. The oily base which solidifies after a short time is recrystallised from alcohol. It is perfectly white and pure. This method gives a nearly theoretical yield.—A. L.

On a New Dihydroxy-naphthalene. A. Claus. J. Prakt. Chem. 39, 315—317.

DAHL'S γ - β -naphthylamine sulphonie acid is, according to Forsling's researches, $C_{10}H_7(NH_2)(SO_3H)$ [$NH_2:SO_3H=1:1'$] (this Journal, 1887, 72). He bases his conclusions on the preparation of a dichloronaphthalene obtained from it, melting at 48° C. The author prepared a hydrazine sulphonie acid, and from this an α -naphthalenesulphonie acid, so that there is no doubt left that the sulphonie group is in the alpha position.

By boiling the diazo-compound of Dahl's acid a β -naphtholsulphonie acid is obtained, which on fusing with caustic soda yields a β - γ - α -dihydroxynaphthalene [the letter γ is used to indicate that it is not yet definitely known which alpha position the sulphonie group is in]. The dihydroxynaphthalene melts at 134°—135° C., is with difficulty

soluble in cold alcohol and chloroform, easily in ether, benzene, and acetone, and crystallises best from benzene in short prisms. It reduces silver nitrate especially in a solution of ammonia. Ferric chloride produces a blue coloration, disappearing, however, at once, and a colourless precipitate separates, changing to a copper-red on addition of more ferric chloride. The alcoholic solution of the dihydroxy-compound does not show fluorescence. Chromic acid produces on heating a black precipitate. The dihydroxy compound forms a diacetyl compound, melting at 73° C.

On heating β -naphthol- γ - α -sulphonates with phosphorus pentachloride a chloronaphthol and a dichloronaphthalene are obtained, the former melting at 128° C., the latter at 48° C., and therefore identical with Forsling's dichloronaphthalene.—A. L.

On the Diamidobenzophenones. H. Wichelhaus. Ber. 22, 988—989.

DIAMIDOBENZOPHENONE from rosaniline is said to be identical with the alpha-compound obtained by Städel and Pauer. All their properties correspond with the exception of their melting points, which were observed at 172° C. and 237° C. To become clear as to this difference, diphenylmethane was converted, according to Städel and Pauer's method, into dinitrodiphenylmethane (melting point 183° C.), then by oxidation into dinitrobenzophenone (melting point 189° C.), and finally by reduction into diamidobenzophenone, melting at 237° C., the same temperature at which the diamidobenzophenone obtained from rosaniline, melts. Thus the complete identity of the two compounds is established. This ketone is easily reduced in an alcoholic solution by sodium amalgam, forming a carbinol, melting at 98° C., with difficulty soluble in neutral solvents, easily, however, in acids. Both compounds form tetrazo colouring matters, useful for dyeing cotton.—A. L.

Synthesis of Rosanilines from Amidobenzophenones and Aromatic Amines in the Presence of Halogen Carriers. O. Mühlhäuser. Dingl. Polyt. J. 271, 592—596.

THE author, after reconsidering the theoretical aspect of the formation of dyes from amidobenzophenones, gives a historical sketch of their production. A table is appended in which the most important of these dyes are enumerated, along with the substances from which they are prepared. "The Badische Anilin und Soda Fabrik" and the "Actiengesell. f. Chem. Ind. Basel" chiefly manufacture: tetramethyldibenzyl-, tetraethyldibenzyl-, pentamethyl- α -naphthyl-, and tetraethyl- α -naphthyl-pararos-aniline, and they are known under the names of Benzyl Violet B, 2 B, Victoria Blue 4 R and 2 B respectively.

For the production of these dyes equal molecules of amidobenzophenone, amine, and halogen carrier are mixed together. In many cases the reaction takes place with only a slight rise in temperature. In certain cases, however, a violent reaction must be prevented by cooling or addition of indifferent solvents, e.g., aromatic hydrocarbons. With other mixtures, again, it is necessary to heat to 100° to bring about the desired reaction. It is always advantageous to have an excess of aromatic amine in order to keep the mixture as neutral and fluid as possible.—A. R.

On the Preparation of Rosanilines from Aromatic Acid Chlorides and Tertiary Amines. O. Mühlhäuser. Dingl. Polyt. J. 272, 44—46.

By the action of acid chlorides on tertiary monamines in the presence of substances favouring condensation, dyes belonging to the rosaniline group are formed. The author gives a historical sketch of the numerous processes for the production of these colouring matters by the above method. Since 1883 the "Badische Anilin und Soda Fabrik" and the "Gesellschaft für Chemische Industrie" (Basel) have manufactured hexamethyl- and hexa-ethylpararos-aniline, also trimethyltriphenyl-pararos-aniline on the principles of O. and E. Fischer's acid chloride process.

To prepare substituted rosanilines of symmetrical constitution, e.g., hexamethyl- or trimethyltriethylrosaniline,

carbon oxychloride is made to react on the tertiary base in presence of the chloride of zinc, iron, or aluminium. The acid chloride which is first formed reacts on the excess of tertiary base with production of the corresponding colouring matter.

When it is a question of preparing substituted rosanilines of which only two-thirds of the substituted groups are symmetrical, e.g., pentamethylphenyl- or tetramethyldiphenyl-rosaniline, carbon oxychloride is allowed to react on the tertiary amine to such an extent only, that the reaction stops with the formation of the acid chloride; this is effected by using no condensing substance or only a very weak one. On then treating the reaction product, which consists of an acid chloride, an amine and its hydrochloride with dilute caustic soda, the chloride is hydrolysed. Brine and unchanged amine may be removed by decantation or filtration, and the amidobenzoic acid is now obtained from the solution by precipitating with hydrochloric acid. After drying, the acid is reconverted into its chloride with PCl_5 , and the chloride in its turn is acted upon by the required amine in presence of aluminium chloride. Excess of amine may then be removed by steaming or by boiling with hydrochloric acid.—A. R.

Tartrazines and Azo-Dyes. R. Meyer. Mittheil. des K. K. Tech. Gew.-Museums, 1889, 49—55.

DYESTUFFS of the tartrazine class have been obtained by substituting, on the one hand, phenylhydrazine sulphonic acid by its homologues and the naphthylhydrazine sulphonic acids, and on the other hand, substituting dihydroxytartaric acid by such double ketones as benzil and phenanthraquinone. The dyestuffs, formed from benzil and phenanthraquinone by condensation with phenylhydrazine sulphonic acid, have the following constitutions:—

In the phenanthraquinone compound two of the benzene rings are directly united in addition to being connected through the $-\text{C}-\text{C}-$ group, which fact finds expression in the reddish-yellow colour of the dyestuff, the benzil dyestuff being a pure yellow.

The tartrazines closely resemble the mixed azo-dyes, as the constitution of the two classes of bodies show:—

I. being the ordinary formula of the osazone of dihydroxytartaric acid or of unsulphonated tartrazine; II. that of a mixed azo-dye. It is possible that the first formula represents an unstable compound which at the moment of formation undergoes a molecular change and becomes constituted as in the second type. This is supported by the fact discovered by Zincke that the hydrazone of α -naphthoquinone is identical with benzene-azo- α -naphthol. Again, the author finds that the hydrazone of mesoxalic acid prepared by E. Fischer is identical with benzene-azomalonic acid obtained by saponifying the product of the action of diazobenzene chloride on the sodium compound of diethylmalonic ether. Japp and Klingemann, also, find the benzene-azo-propionic acid prepared by them identical with Fischer's hydrazone of pyruvic acid. Further, A. Bernthsen points out that the hydrazone of acetylaldehyde has all the properties of an azo-dye. Then again, whilst Japp and Klingemann have proved that benzene-azo-acetone is a hydrazone compound and not an azo-body, Claisen and Baeyer showed that certain singular compounds behaved, in certain reactions, more like azo-bodies. In the present state of knowledge it is impossible to fix the constitution of these bodies, the mixed azo-dyes and the hydrazones, with certainty, for they almost appear to be substances so susceptible of molecular change as to react as azo-dyes in some cases and as hydrazones in others.

—E. B.

PATENTS.

Preparing Colouring Matters for Dyeing and Printing. J. H. Johnson, London. From H. Caro, Mannheim, Germany. Eng. Pat. 5305, December 29, 1879. (3rd Edition.) 6d.

This patent describes the manufacture of Naphthol yellow S (see also this Journal, 1882, 63). It consists chiefly of the sulphonic acids of dinitro- α -naphthol, and is prepared by the action of nitric acid upon the sulphonic acids of α -naphthol which are produced by the action of sulphuric acid on α -naphthol in such a way as to produce higher sulphonation products than the monosulphonic acid. By the action of nitric acid, these sulphonic acids and more especially a trisulphonic acid of α -naphthol are converted into nitrosulphonic acids, and chiefly into sulphonic acids of dinitro- α -naphthol.

The sulphonation is performed by means of fuming sulphuric acid, and from time to time a sample is taken from the mixture, dissolved in an excess of nitric acid and diluted with water. If much precipitate be formed and the filtered solution give little or no precipitate on the addition of caustic potash, the action of the sulphuric acid must be continued either by raising the temperature or adding more sulphuric acid. The sulphonation is complete when a sample of the naphthol sulphonic acids after treatment with nitric acid remains clear on the addition of water, and gives with caustic potash an abundant precipitate of the potassium salts of the dinitronaphthol sulphonic acids. The whole melt may then be similarly treated with nitric acid, or the sulphonic acids may be first purified by conversion into their alkaline salts, then separated or not by crystallisation and treated directly with nitric acid. The nitrosulphonic acids thus obtained are converted into their soluble calcium salts, which by the action of alkaline carbonate yield the corresponding alkaline salts. The following quantities are given for working the patent. 10 parts by weight of α -naphthol are mixed with 20 parts by weight of fuming sulphuric acid containing 25 per cent. of sulphuric anhydride, and the mixture is kept well stirred at 40° to 50° C. until a sample is soluble in water. 18 parts of fuming sulphuric acid of 70 per cent. anhydride are then added at the same temperature, and the mixture is kept well agitated until a sample gives the reaction with nitric acid described above. The melt is then diluted with 75 parts of water and gradually mixed with 25 parts of nitric acid of sp. gr. 1.38. The temperature of the mixture is not allowed to rise above 50° C. After standing 12 hours in the cold, chiefly a monosulphonic acid of dinitronaphthol crystallises out and is converted into the potassium, sodium or ammonium salt. The mother-liquor is treated with an excess of caustic lime, and the soluble calcium salts thus produced are decomposed by means of alkaline carbonates with the formation of the corresponding alkaline salts, preferably for commercial purposes into the potassium salts. The patentee claims:—
1. The preparation of a trisulphonic acid of α -naphthol or of such sulphonic acids of α -naphthol, which upon treatment with nitric acid will retain one or more of their sulphonic groups and become changed into nitrosulphonic acids and chiefly into the sulphonic acids of dinitronaphthol described.
2. The preparation of nitrosulphonic acids of α -naphthol, and chiefly of the sulphonic acids of dinitronaphthol by the action of nitric acid upon the above described sulphonic acids of α -naphthol as described.—T. A. L.

Improvements in the Production of Colouring Matters. C. D. Abel, London. From the Farbwerke vorm. Meister, Lucius and Brüning. Höchst-on-the-Maine, Germany. Eng. Pat. 9600, July 2, 1888. 6d.

This patent describes the production of the dyestuff "Rhodamine" from fluorescein chloride (Bayer, *Annalen*, 183, 18) by acting on it with primary and secondary amines. The reaction takes place according to the following equation:—

Fluorescein chloride is obtained by the action of phosphorus pentachloride on fluorescein and yields red colouring matters when treated with the following amines:—mono-ethylamine, diethylamine, mono-methylamine, dimethylamine, *m*-amido-dimethylaniline, *m*-amido-diethylaniline, *m*-amido-dimethyl-*o*-toluidine, *m*-amido-diethyl-*o*-toluidine, *m*-amido-mono-methylaniline, *m*-amido-monoethylaniline, *o*-toluidine, xylylidine, ψ -cumidine. The following amines yield reddish violet colouring matters:—aniline, monomethylaniline, monomethylamine, α -naphthylamine, phenylhydrazine, *m*-amido-dimethyl-*p*-toluidine, *m*-amido-diethyl-*p*-toluidine. Violet colouring matters are obtained from diphenylamine, benzidine, *p*-phenylene diamine, *m*-phenylene diamine, β -naphthylamine, *p*-toluidine. Paramido-diphenylamine yields a blue colouring matter. The reaction is not confined to ordinary fluorescein chloride, but also takes place with the chlorine and bromine compounds of fluorescein chloride. The method of application is described in the two following examples:—

(1.) 3.7 parts of fluorescein chloride are heated with 1.9 parts of aniline, and 3 parts of zinc chloride to 210° C. for one hour. The melt is dissolved in alcohol containing hydrochloric acid, or in 7 parts of concentrated sulphuric acid, at a temperature of about 60° C. On pouring the solution into water the dyestuff is precipitated and is then filtered off, washed and dried. (2.) 5 parts of fluorescein chloride are heated in an autoclave with 4 parts of diethylamine hydrochloride, 5 parts of sodium acetate (or 1.6 parts of lime), and with or without zinc chloride and alcohol, of each of which 5 parts, for 12 hours to 200° C. The colouring matter is extracted by means of alcohol containing a sufficient quantity of hydrochloric acid, the alcohol is distilled off and the residue purified by dissolving it in very dilute hydrochloric acid and precipitating the dyestuff by salt.

—T. A. L.

Improvements in the Manufacture of Methylene-blue and allied Colouring Matters. J. Y. Johnson, London. From The Badische Anilin und Soda Fabrik, Ludwigshafen-on-the-Rhine, Germany. Eng. Pat. 10,314, July 16, 1888. 6d.

By the action of alkalis on Methylene red or preferably by treating *p*-amidodimethylaniline with oxidising agents and thiosulphuric acid, one of the compounds obtained is a well crystallised substance possessing acid properties and capable of reacting analogously to *p*-amidodimethylaniline. Its formula is $\text{C}_{16}\text{H}_{11}\text{N}_2\text{S} \cdot \text{SO}_3\text{H}$. When equal molecules of this body and of dimethylaniline are oxidised in a neutral aqueous solution, a green crystalline indamine is obtained almost insoluble in water and having the composition $\text{C}_{16}\text{H}_{10}\text{N}_2\text{S}_2\text{O}_3 + \frac{1}{2} \text{aq}$. On heating this with a solution of zinc chloride or of a cupric salt it is converted into Methylene-blue. The method of working the process is as follows:—6 parts by weight of dimethylaniline are dissolved in about 18 parts by weight of hydrochloric acid of sp. gr. 1.16, and to this is added a solution containing 3.8 parts of sodium nitrite in 6 parts of water. The nitrosodimethylaniline hydrochloride thus formed is reduced by adding about 30 parts of the above hydrochloric acid, and then in small quantities about 10 parts of zinc dust. The solution of *p*-amidodimethylaniline hydrochloride is then diluted with 250 parts by weight of water, and any free acid neutralised by means of an alkali. 16 parts of sulphate of alumina and 13 parts of sodium thiosulphate are added, and immediately afterwards a solution of 5 parts of potassium bichromate in 60 parts of water is run in quickly, forming the compound $\text{C}_{16}\text{H}_{11}\text{N}_2\text{S} \cdot \text{SO}_3\text{H}$. The substance is not separated, but is treated with a solution containing 6 parts of dimethylaniline dissolved in 6 parts of hydrochloric acid and 6 parts of water, and the whole is shortly afterwards

oxidised by running in 14 parts of potassium bichromate dissolved in 160 parts of water, the whole being thoroughly agitated. The green crystalline indamine separates out and is converted into Methylene-blue by boiling it for half an hour with about 50 parts by weight of a solution of zinc chloride of sp. gr. 1.5. On cooling, crystals of Methylene-blue separate out, which may be purified by solution in water and precipitation by salt. The quantity of potassium bichromate in the second oxidation described above is about one-third more than is actually required. The excess is necessary in order to prevent the formation of leuco-compounds in the subsequent operation. Homologous compounds to the dyestuff above described are obtained by employing diethylaniline or methylethylaniline in place of dimethylaniline. Colouring matters allied to Methylene-blue are obtained by substituting the equivalent amount of aniline, *o*-toluidine, methylethylaniline or diethylaniline for the 6 parts of dimethylaniline mentioned in the second stage of the process described above. The amine which has yielded the best result is *o*-toluidine.—T. A. L.

Manufacture of Brown Colouring Matters which Dye Cotton without the use of a Mordant. C. D. Abel, London. From The Actien Gesellschaft für Anilin Fabrikation, Berlin, Germany. Eng. Pat. 10,653, July 23, 1888. 6d.

THESE colouring matters are obtained by the action of the sulphonic acids of diazo-compounds on the orange colouring matter obtained by combining tetrazo-diphenyl first with one molecule of salicylic acid and acting with the intermediate compound thus formed on one molecule of resorcinol. 47 kilos. of this orange colouring matter are dissolved in 4,000 litres of boiling water and 25 kilos. of caustic soda of 40° B. When cool, 20 kilos. of *p*-diazobenzene sulphonic acid suspended in 600 litres of water are slowly added. The sparingly soluble colouring matter separates out, and the precipitation is completed by the addition of salt. The same substance is obtained if the intermediate product from one molecule of tetrazo-diphenyl and one molecule of salicylic acid acts on the colouring matter obtained by the action of molecule of *p*-diazobenzene sulphonic acid on one molecule of resorcinol. To obtain the colouring matter according to this method, 19.5 kilos. of benzidine are dissolved in 48 kilos. of hydrochloric acid and 800 litres of water and diazotised by 6.9 kilos. of sodium nitrite; the diazo solution is added to a solution of 15 kilos. of salicylic acid, 30 kilos. of sodium carbonate, 14 kilos. of caustic soda of 40° B., and 1,200 litres of water, and the whole mixture is then stirred into a solution containing 36 kilos. of the colouring matter from *p*-diazobenzene sulphonic acid and resorcinol in 1,000 litres of water. The mixture is then allowed to stand for 24 hours, when it is heated and the colouring matter precipitated by salt, filter-pressed, and dried. Yellowish-brown shades are obtained by using *m*-diazobenzene sulphonic acid in place of the para-compound, whereas naphthionic acid gives redder shades. The substitution of toluidine for benzidine makes no important change in the shade.—T. A. L.

Improvements in and relating to the Manufacture of Colouring Matters. H. H. Lake, London. From K. Oehler, Offenbach-on-the-Main, Germany. Eng. Pat. 10,845, July 26, 1888. 6d.

THE diazo-compounds of the amido-phenol and amido-cresol sulphonic acids combine with α -naphthylamine to form azo dyestuffs of the general formula—

These azo-compounds can be re-diazotised and combined with α - and β -naphthol sulphonic acids to form new tetrazo dyestuffs.

21.5 lb. of sodium amido-*p*-phenol-sulphonate and 7 lb. of sodium nitrite are dissolved and poured slowly into an excess of hydrochloric acid. When the diazotisation is complete, a solution of 20 lb. of α -naphthylamine hydrochloride is added, and the reaction accelerated by heating to 40°–50°. The precipitate, which has the composition $C_6H_3(OH)(SO_3H) = N.C_{10}H_6NH_2$, forms dark green

crystals dissolving in ammonia with a brownish-orange and in concentrated sulphuric acid with a violet colour. It is insoluble in water, and, after filtering off and washing, it is dissolved in a moist state in 10 lb. of ammonia of 17 per cent., 7 lb. of sodium nitrite are added, and the whole poured into hydrochloric acid cooled to 0°. The diazotisation is complete when the blackish flakes which first form change to a pure brown, and the whole is then poured into an alkaline solution of 38 lb. of β -naphthol disulphonic acid R. (Ger. Pat. 3229). The dyestuff forms as a black precipitate, and is purified by crystallisation from water. Its solution in concentrated sulphuric acid is blue. It dyes wool violet to violet-black according to the strength. In place of the R. salt 28 lb. of Schaeffer's sodium β -naphthol sulphonate or of sodium α -naphthol sulphonate may be employed with the formation of similar dyestuffs. Homologous colouring matters are obtained by substituting the sulphonic acids of amido-*o*-cresol and amido-*p*-cresol for the amido phenol in the process described above. The patent contains a table giving the reactions with various reagents of the dyestuffs obtained from these substances. The dyestuffs are said to be very fast to light.—T. A. L.

The Production of New Colouring Matters. W. G. Thompson and W. H. Claus, Manchester. Eng. Pat. 14,836, October 16, 1888. 6d.

THIS invention describes the production of colouring matters by acting with diazo- or tetrazo-compounds on decoctions of cutch, quercitron bark, logwood, and fustic. By the action of the diazo-compounds of benzene and its homologues, amido-azo-benzene, α - and β -naphthylamines and the sulphonic acids of all the foregoing and phenylene diamine on decoctions of cutch, quercitron bark and logwood, colouring matters are obtained which dye wool and mordanted cotton and are more especially useful for cotton printing. The shades vary from yellow to brown. The following is an example of the method for obtaining the colouring matter from toluidine and cutch. 107 lb. of toluidine are dissolved in 1,800 lb. of water containing 230 lb. of hydrochloric acid of 30° Tw., and diazotised by the addition of 73 lb. of sodium nitrite in 200 lb. of water. After one minute 280 lb. of cutch dissolved in 1,000 lb. of water are added, and the colour is salted out, filtered, and dried. The colouring matters from diazotised benzidine, toluidine, and benzidine disulphonic acid combined with the above wood extracts are said to be rather insoluble. 92 parts of benzidine when diazotised combine with 280 parts of solid cutch, 240 parts of logwood extract of 51° Tw., 400 parts of quercitron extract of 51° Tw., or 280 parts of fustic extract of 51° Tw. If intermediate compounds be formed by using only half the above quantities of the extracts, these can be further combined with amines, phenols, and their sulphonic acids, forming a variety of shades. (See also this Journal, 1888, 619.)—T. A. L.

Improvements in the Preparation of Nitro- and Amido-phenols from the corresponding Anides. A. Deninger, Dresden, Germany. Eng. Pat. 16, January 1, 1889. 6d.

WHEN a salt of diazobenzene is heated in an aqueous solution in presence of nitrous acid, *o*-nitro-phenol is obtained. If, however, the mixture is allowed to decompose spontaneously, the product formed is *p*-nitro-phenol. From *o*-toluidine are produced respectively *o*-nitro-cresol [$CH_3.OH:NO_2 = 1:2:3$] with a melting point 69°, and *p*-nitro-cresol [$CH_3.OH:NO_2 = 1:2:5$] with a melting point 96°; *p*-toluidine yields *p*-nitro-cresol [$CH_3:NO_2:OH = 1:3:4$], melting point 34°. Naphthylamine forms nitro-naphthol, melting point 128°, benzidine yields dinitrodiphenol, melting point, 260°, and toluidine gives dinitrodieresol, melting point 270°, when similarly treated. The following is the method of applying the invention:—600 grms. of crude sulphuric acid are mixed with one litre of water and 250 grms. of aniline and cooled to 15°. A solution is then prepared containing 750 grms. of sodium nitrite in one litre of water, and one-third of this solution is added slowly in order to diazotise the aniline. The remainder is then added quickly and sufficient sulphuric acid stirred

in under constant agitation to raise the temperature of the mixture to 70°. Considerable frothing takes place, and, after cooling, the mixture is filtered, the black residue on distillation with steam yielding 60 per cent. of *o*-nitro-phenol. The *p*-nitro-phenol remains behind, and is extracted by means of boiling water, yielding about 16 per cent. In order to obtain a larger yield of the para-compound the diazotisation must be performed at a temperature below 10°, and after treating as described above is allowed to stand for some days at 15°–20°. The reduction of the above nitro-compounds is performed by means of tin and hydrochloric acid, or by sulphuretted hydrogen and ammonia.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

An Artificial Silk. De Chardonnet. Compt. Rend. 108, 961–963.

COTTON or the sulphited pulp of young wood is treated with nitric acid, and then dissolved in a mixture of ether and alcohol—38 to 42. This collodion is placed in a copper vessel and forced by air pressure through capillary glass tubes, the outlets from which are surrounded by water. In the figure, A shows the glass tube, the lower end of which dips

into the collodion; B is a second tube enveloping the first, and receiving a supply of water by the opening C. The collodion, forced through the orifice A, solidifies as it comes into contact with the water, forming a thread which is seized by a clip and carried forward to the bobbins in the usual way. It is stated that the cellulose is denitrated by soaking it in a bath of nitric acid of sp. gr. 1.32, the temperature of which is allowed to fall slowly from 35° to 25° C. At the end of this process the cellulose has become gelatinous, has lost its explosive properties, and very readily absorbs colouring matters and salts. In density, breaking strength, and elasticity it compares very favourably with natural silk, and in lustre even surpasses it.—A. R. D.

PATENTS.

Improvements in Apparatus and Means for Cleaning Vegetable Fibres. A. Figge, London. Eng. Pat. 4887, March 31, 1888. 8d.

THE apparatus consists of a vessel fitted with electrodes, in which a perforated drum revolves. The drum contains the materials to be treated, and the vessel contains lukewarm water and a small quantity of blood. When a current of electricity is passed between the electrodes a fermentation or putrefaction of the blood is set up which extends to the glutinous matter encasing the fibres, rendering it readily soluble. In certain cases salt may be added to the liquid.

—E. J. B.

Improvements in Methods of and Apparatus for Utilising Peat Fibre. G. A. Cannot, London. From G. H. Beraud, Maestricht, Holland. Eng. Pat. 8742, June 14, 1888. 1s. 3d.

THIS invention relates to the utilisation of the fibre of peat by spinning it into threads either alone or mixed with a small quantity of wool, cotton, or other fibrous material, and manufacturing it into textile fabrics which can be used for a variety of purposes, such, for example, as cloth, wrappers for meat, fish, and food stuffs, soles for boots, chest protectors, screens, curtains, &c. The material is first broken up into fibres and freed from dirt by treatment in a beating engine of special construction. It is then converted into tow by another machine called a breaking engine, after which it may be spun into thread. The above processes may be preceded by a chemical treatment of boiling in alkaline solutions. Or it may be soaked for 6–12 hours in a 5 per cent. sulphuric or hydrochloric acid solution, after which it can be bleached with chlorine or sulphurous acid. The specification contains 15 drawings of the various machines and apparatus employed.—E. J. B.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Utility of Good Commercial Glycerin. Dyer, 1889, 24.

COMMERCIAL glycerin, which is usually from 1.16 to 1.25 specific gravity, is much used in the dyeing industry as a solvent for many aniline dyes, also as an antiseptic in solutions which contain albumen, casein, and other substances, for which purposes it is not necessary to use the white glycerin except for delicate colours, when it must be absolutely free from mineral matter. It can also be used with bleaching materials to prevent the penetrating odour, and bleaching can then be performed in the driest weather with open windows without the goods becoming stiff or brittle. It also acts as a preventive of "stock stains" in goods which are warehoused a long time. A mixture for such use is the following:—Dextrin, 10 lb.; glycerin, 24 lb.; sulphate of alumina at 1.5 specific gravity, 2 lb.; and water, 51 pints.—R. L. W.

Removing Starch from Cotton. Dyer, 1889, 26.

IN order to remove starch completely from too heavily dressed cotton, which has to be subsequently dyed, use is made of the decomposition which starch undergoes by the action of malt extract. For 10 lb. of yarn a chilled bath containing 3 oz. of malt and 3 oz. of glycerin is prepared, and the cotton after "wetting out" worked in this till free from starch.—R. L. W.

The Composite Indophenol-Indigo Vat. A. Kertész. Chem. Zeit. 13, 626–627.

THIS article is a criticism on a paper previously published by Noelting in the same Journal (this Journal 1889, 189; see also 1889, 282).

A series of experiments on the large scale were undertaken by the author with a view to obtaining data for an exact comparison of the relative costs of the composite and pure indigo vats. The concentrated composite vat was made according to the directions given. As a preliminary trial showed that the indophenol tended to float about on the surface of the vat and so escape reduction, it was made into a paste with hot water before being mixed with the ground indigo. A good quality of Bengal indigo, containing 62 per cent of colouring matter, was used. Two vats were prepared as follows:—No. 1 vat was set with 33 lb. of indigo costing 165s.; No. 2 vat was set with 22 lb. of indigo and 7 lb. of indophenol, together costing 142.3s. 172 pieces = 9,753 yards of cloth, were dyed in No. 1 vat, against 165 pieces = 9,309 yards, in No. 2 vat. There was consequently a gain equal to 11 per cent. of indigo with the composite vat.

This amount is below that stated to be gained, namely 25 per cent., but is still considerable. But the relative costs of reduction have yet to be taken into account. In the case of the new vat, owing to the necessity of preserving the vat as long as possible, the cost is comparatively high. Of the vats now in use, namely, that of lime and zinc dust, the caustic soda and zinc dust, and the sodium hydrosulphite vat, the first two require renewing more frequently than the latter, which is therefore preferred whenever it is desired to keep the vat; and this being especially the case with the composite vat, the hydrosulphite method of reduction is selected and modified to suit the special case.

As far as can be judged from a comparative dye-trial lasting five days, the new vat keeps in better condition than the sodium hydrosulphite vat, but not so well as a vat made with lime, caustic soda, and zinc dust, and the manipulation of the goods is rendered slightly more difficult through the workmen requiring to wear india-rubber gloves on account of the strong alkalinity of the vat.

The costs of reduction with the different vats are as follows:—

Lime and zinc dust	4½	per cent. of the value of the indigo.
Caustic soda and zinc dust 5½	"	"
Sodium hydrosulphite	9½	"
Composite vat	15½	"

The composite vat, as stated above, effects a reduction of cost equal to 14 per cent. of indigo, but when the extra cost of reduction is deducted from this percentage, only a gain of 4½ per cent. is realised by the new vat as against the hydrosulphite, and little or no gain against the other vats.

The shades obtained with the composite vat are rather more purplish than those of pure indigo; washing or exposure to light renders them slightly duller than the latter. Indophenol can be detected on the fibre by boiling with sodium hydrate of 14° to 18° B., and adding ether to the solution; pure indigo dissolves in the ether with a pale blue colour, indophenol colours it violet.—E. B.

Tolylene Orange. F. V. Kallab. Mittheil. des K. K. Tech. Gew. Museums, 1888, 114—120.

TOLYLENE orange is the name of a mixed tetrazo-dye produced by combining cresolcarboxylic acid and tolylene-diamine sulphonic acid with tetraxiditoly. It is sold in two shades, G(TOG) and R(TOR).

The commercial product is the sodium salt. It appears as an orange-brown powder tolerably easily soluble in water. Its aqueous solution is rendered brighter in colour by the addition of a little caustic soda; further addition produces an orange-brown precipitate. Concentrated sulphuric acid dissolves the dye with a violet colour.

Tolylene Orange G(TOG), is the first orange substantive dye which appeared in the market. It yields shades fast to soap, and ranging from the most delicate "ivories" and "creams" through the whole scale of buffs, down to full shades of orange closely resembling chrome orange, but possessing advantages over the latter in not being tarnished by hydrogen sulphide, and not injuring the feel of the cloth. Again, the shades are faster to acids than chrome orange, and faster to light than the reds of the substantive class. The dye is very suitable in calico printing for the production of pad buffs and creams, and is strongly recommended as a substitute for iron buff, especially for padding over colours liable to be injured by this colour. Chrysamine, which has been in use some time as a substitute for iron buff, is not as red as the latter, and no satisfactory method of overcoming this deficiency is known. The various methods in use, such as leaving the pink stain uncleaned on cloth printed with alizarin colours, mixing caustic soda with the chrysamine, and adding magenta or benzopurpurin to the padding colour, all have their drawbacks. Tolylene orange, again, is not so sensitive as chrysamine to the action of copper salts or metallic copper. It is best applied in a wooden dye-bath along with soap and phosphate of soda, the water being first softened by boiling with soap, and the scum removed. In dyeing full shades on cloth printed with fast colours, the

bath may be boiled; in the case of cloth printed with aniline colours the temperature should not exceed 45°. 8—10 minutes' dyeing will suffice for printed cloth, plain cloth should be worked at the boil for a longer time. In the case of medium and pale shades, it is preferable to pad either by padding or printing machine since the dye is apt to be too rapidly, and consequently unevenly, absorbed from a dye-bath. The following receipt is given for a medium pad shade: 2 parts of Tolylene orange G are dissolved in 1,000 parts of boiling water containing 20 parts of sodium phosphate, and 5 parts of soap. The solution is then mixed with 1,000 parts of gum tragacanth paste (1:20), and boiled for 15 minutes, then strained and padded. The pieces are passed through a Mather and Platt's steam aniline ager or steamed for a short time, washed and finished.

The steaming can be dispensed with in many cases, and the pieces finished after lying for a few hours.

A printing colour is made by mixing starch paste, gum tragacanth paste, tolylene orange G, and glycerin. The calico is printed, steamed for an hour, and washed in a cold bath containing 3 per cent. of ground chalk. The colour is not very fast to soap, but is suitable for many purposes, such as linings for example.

Discharge effects are obtained by printing a thickened mixture of stannous acetate for white, and Persian berries, alizarin, Methylene blue, Alizarin blue, logwood, along with suitable mordants, and stannous acetate for coloured patterns.

Tolylene orange acts as mordant for basic dyes, and a variety of compound shades can thus be obtained. Care must be taken that the material dyed with the Orange is well rinsed before the basic dye is applied.

Linen and jute dye similarly to cotton; China grass and hemp take a redder shade. Animal fibres, dyed under the same conditions as the vegetable fibres, are coloured more yellow than the latter. Silk dyes well in baths of boiled-off liquor "broken" with acid. Wool is dyed for an hour at the boil in a bath containing 10 per cent. of sodium sulphate; the shades obtained are fast to milling.

Tolylene Orange R, in general resembles the G shade, but gives redder shades, which are, however, scarcely so fast. Salmon shades are obtained by using only a little of the dye, larger quantities give shades like chrome-orange which has been strongly lined or topped with magenta. Tolylene orange R is applied in the same way as the G shade.—E. B.

PATENTS.

Improvements in Apparatus for Printing on Fabrics.
J. Kerr, Church. Eng. Pat. 9124, June 22, 1888, 8d.

This invention relates to the construction of duplex printing machines, and enables two sides of a fabric to be printed simultaneously without the use of central cylinders or bowls, or blankets, when so desired the impressions on the two sides of the fabric being made to exactly coincide.

One or more pairs of printing rollers are provided, the individual pairs being placed opposite one another. The fabric to be printed is passed between the pair or pairs of rollers so as to be in contact with each roller of the pair, or all the rollers at the same time. The rollers may print the same pattern on each side, or different patterns may be printed on the two sides. In patterns printed with one colour, one pair of rollers can be used, but in printing with more than one colour, the number of rollers will correspond with the number of colours. Both sides of one fabric, or one side of each of two fabrics placed back to back can be printed with the same or different patterns.

The arrangement of the pairs of rollers is such, that the "nips" are in parallel planes to each other, in this respect differing from ordinary printing machines, wherein the centre lines of the "nips" radiate towards the centre of the bowl. Two drawings are given.—E. B.

Improvements in Linings for Bleaching Kiers, Vats, Dye Tanks, and other Analogous Receptacles. R. P. Frist, Wilmington, Delaware, U.S.A. Eng. Pat. 18,773, December 22, 1888. 6d.

BLEACHING kiers have formerly been made of wood, or of iron lined with wood, galvanised, or even enamelled. These methods of lining are open to objection. The objections are overcome by lining the kier or tank with chemically prepared or treated fibre such as "celluvert" (a product described in Eng. Pat. 9319 of 1885, this Journal, 1885, 751), vulcanised fibre, parchment fibre, and like products resulting from the treatment of vegetable fibres with acids or acid compounds. Of these materials, "celluvert" is preferable, since, after the lining has been in use some time, a skin or enamel is formed on it. The fibre is impervious to moisture; steam does not affect it, whereas wood becomes soaked, swells, and warps.

The prepared fibre lining, moreover, is of much less thickness than a wood lining, so that it detracts much less from the capacity of the kier. The lining is preferably made in the form of slabs, which may be secured to the kier or tank in any suitable way, for example, by means of bolts passing through the shell, and lining of the kier, and having inside the kier cap-nuts, made of, or covered with cellulvert, &c., of sufficient size to cover a slot or enlarged opening in the lining, which allows for the slight expansion, and contraction of the same.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Researches on the Thionic Series. Berthelot. Compt. Rend. 108, 773—779.

THE author has determined the heats of formation of the acids of the thionic series by oxidising their potassium and sodium salts with a solution of bromine in potassium bromide. Complete conversion into sulphuric acid takes place in a few minutes with hyposulphurous, trithionic, tetrathionic, and pentathionic acids, but in the case of dithionic acid, oxidation takes place so slowly that the method is useless. The author deduces the heats of formation of these thionic acids from the number of calories evolved during the oxidation, making due allowance for the heats of formation of sulphuric acid, of water, and of hydrobromic acid, together with the heat of solution of bromine in potassium bromide, the heat of neutralisation of the thionic acid, and the heat disengaged by the saturation of an equivalent of potash or soda with sulphuric acid. Below are the calories disengaged during the formation of the molecular weight of each acid in grms.

	Cal.
$S_2O_3 \cdot H_2O$	79.4
$S_3O_3 \cdot H_2O$	207.8
$S_4O_3 \cdot H_2O$	211.4
$S_5O_3 \cdot H_2O$	205.2
$S_6O_3 \cdot H_2O$	215.8

It will be noticed that in each case the proportions approximate to 40 calories for each equivalent of oxygen directly united with the sulphur atom. This is also the case with sulphurous, sulphuric, and persulphuric acids.

—A. R. D.

The Action of Alkalis on the Acids of the Thionic Series. Berthelot. Compt. Rend. 108, 925—930.

THIS communication is intended to supplement the author's note (preceding abstract) on the heats of formation of the acids of the thionic series. He now describes the behaviour of these acids with an excess of alkali in dilute solution. Conversion into sulphites and thiosulphates (hyposulphites) take place with evolution of heat. The re-arrangement of the molecular groups of the thionic acids really involves an absorption of heat, but this absorption is more than

counterbalanced by the heat of neutralisation of the increased number of acid molecules produced. His results lead him to advance the theory that the thionic acids should be considered as derivatives either from thiosulphuric (hyposulphurous) or sulphurous acids or from both, by the elimination of molecules of water.—A. R. D.

On the Solubility of some Salts. H. Le Chatelier. Compt. Rend. 108, 801—803.

THE author still maintains the impossibility of a vertical tangent to the curves of solubility in the case of calcium chloride. He also complains that B. Roozeboom (this Journal, 1889, 391) has in his calculations neglected the change of volume that accompanies the solution of the salt, and which at the point of fusion, he contends, will materially influence the results. He thinks, however, that Roozeboom and himself are nearer of accord than may at first appear, especially if the former will assent to the proposition that with every abrupt change in the nature of the solvent there is a correspondingly abrupt change in the behaviour of the curve. Roozeboom has already completely accepted the opinion advanced by the author, that a sudden change in the behaviour of the curve of solubility corresponds necessarily to every sudden change in the state of a solid salt, which undergoes solution.

Roozeboom had complained that the author had attributed a too great degree of precision to his experiments. He considers that on a subject so delicate, theory alone can lead to positive conclusions. His formula, which claims absolute rigorousness, contains a denominator holding good to the point of fusion of $CaCl_2 \cdot 6H_2O$ and giving consequently an infinite value for the angular coefficient of the tangent. The author cannot accept this view; he has great confidence in the experiments, but much less in the rigorous formula, which they, in fact, only approach.

Roozeboom neglects in his calculations, as being infinitely small, the change of volume accompanying solution of the salt. But on arriving at the fusing point, this neglected quantity becomes infinitely large in proportion to that which has been preserved, and the formula loses its applicability. (*Études sur les Conditions de l'Équilibre*, B. Roozeboom, Compt. Rend. 108, 22 and 218.)—A. R. D.

On the Oxides of Manganese obtained in the Wet Way. A. Gorgeu. Compt. Rend. 108, 948—951.

HYDRATED protoxide of manganese held in suspension in a mother liquor containing excess of manganese salt absorbs oxygen with the formation of the saturated bibasic manganite $MnO_2 \cdot 2MnO$. Further absorption of oxygen goes on slowly at ordinary temperature till the acid manganite of the formula $MnO_3 \cdot MnO$ is arrived at. Neutral aqueous solutions of manganous salts grow turbid on exposure to the air, the amount of deposit varying inversely with the degree of concentration. From solutions of chloride, sulphate, and acetate it has the composition $MnO_3 \cdot MnO$; from the nitrate, $3MnO_2 \cdot 2MnO$. Probably this deposit is due to the action of oxygen upon the salts already somewhat dissociated by the fact of their solution in water. Iodine (dissolved in potassium iodide) acts very feebly upon hydrated manganous protoxide and upon the carbonate. Upon salts of manganese with acetic and the stronger acids it has no action at all. Chlorine and bromine behave much more energetically, oxidising the protoxide and decomposing the carbonate with ultimate formation of the dioxide. A considerable time is required to effect complete oxidation owing to the formation of intermediate manganites of manganese, which are less susceptible to the influence of the oxidising agent.—A. R. D.

A New Determination of the Specific Gravities of Solutions of Ammonia. G. Lunge and T. Wiernik. Zeits. f. angew. Chem. 1889, 181—183.

GRÜNEBERG (this Journal, 1889, 390—391) lately published a new table of the specific gravities of solutions of ammonia, which table appears to agree very closely with that published years ago by Wachsmuth. The tables of both investigators

are, however, based on determinations performed at different temperatures, and if the necessary corrections are introduced into Wachsmuth's table, who took 12° C. as the normal temperature, it will be found that the agreement with Grüneberg, although still good, is no longer very close. Lunge and Wiernik now made a large number of experiments, in which the specific gravities and actual percentages of ammonia in ammoniacal liquors were determined with the greatest possible care. From these determinations a table was calculated, which agrees very well with Wachsmuth's, corrected for a temperature of 15° C., whereas Grüneberg's figures are a little too low, as will be seen by the comparison of these tables:—

Specific Gravity.	Carius, 14° C.	Grüneberg, 15° C.	Smith, 11° C.	Wachsmuth, corrected for 15° C.	Lunge and Wiernik, 15° C.
0.880	..	35.50	..	35.42	35.60

The Specific Heat of Sulphuric Acid of Various Strengths.
F. Bode. *Zeits. f. angew. Chem.* 1889, 244—245.

THERE exists for the specific heat of hydrated sulphuric acid, a formula by Marignac, viz. :—

$$C = 18n + 8.58 + \frac{334.8}{n} - \frac{2882}{n^2} + \frac{7262}{n^3},$$

in which $C = p \cdot c$ the molecular heat ;

p = the molecular weight of the solution ;

c = the specific heat of the solution per unit of weight ;

n = the number of molecules of water per molecule of SO_3H_2 .

This formula gives accurate results from a certain point, and the results found by calculation agree with those found by experiment. Marignac's formula is, however, only applicable if n , that is the number of molecules of water, be known, and the author therefore calculated a more generally useful table, where the specific heat can be read off directly, after the specific gravity of the sulphuric acid at 15° C. is ascertained.

$^{\circ}\text{B}$ at 15° C.	Specific Gravity.	Specific Heat.	$^{\circ}\text{B}$ at 15° C.	Specific Gravity.	Specific Heat.
66	1.842	0.3315	35	1.320	0.67
63	1.774	0.38	30	1.263	0.73
60	1.711	0.41	25	1.210	0.78
55	1.615	0.45	20	1.162	0.82
50	1.539	0.49	15	1.116	0.87
45	1.453	0.55	10	1.075	0.90
40	1.383	0.60	5	1.037	0.95

The specific heat increases with a rise of temperature.

—S. H.

PATENTS.

Improvements in Purifying or Treating Coal Gas and other Gaseous or Liquid Products of Destructive Distillation, and in part applicable in the Alkali Manufacture.
A. Campbell, London, and W. Boyd, Glasgow. Eng. Pat. 10,186, July 13, 1888. 6d.

See under 11., page 534.

Improvements in the Reduction of Hydrogen Sulphide for the Production of Sulphur therefrom. A. B. Thompson, London. Eng. Pat. 17,183, November 26, 1888. 6d.

THE hydrogen sulphide is reduced to sulphur by means of the fumes obtained by the decomposition of nitrates or nitric acid. Sufficient air must be admitted to reoxidise the nitric oxide formed by the reaction to nitrogen peroxide, and the process then goes on continuously. Drawings are given to show how the operation can be carried out in conjunction with the process patented in 1887 (this Journal, 1888, 626).—E. E. B.

Improvements in the Manufacture of Acetic Acid.

M. Cannon, London. Eng. Pat. 5224, March 26, 1889. 6d.

CRUDE acetic acid is digested with about 3 per cent. of either binoxide of manganese, manganate of soda or other manganate, or permanganate of potash or other permanganate. An equivalent amount of sulphuric or other acid is added to decompose the acetate produced by the decomposition of the oxidant, and the digested acid is distilled, the first 10 per cent. and the last 5 per cent. being rejected. The acetic acid thus produced may be still further purified by repeating the process with 1 per cent. of one of the above oxidising agents. The manganese is recovered from the residue in the still and is used over again.—E. E. B.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

PATENT.

Improvements in the Manufacture of Plate Glass. P. Simon. Sulzbach, Germany. Eng. Pat. 6393, April 15, 1889. 6d.

THE object of this invention is to obtain rolled plate glass with a smooth and even surface. The glass is pressed between rollers with their surface waved, the wave running parallel to the axes of the said rollers, and the wave of the one roller when they are in motion passes in the hollow of the other, so that the space between the two rollers remains constant, and the plate will not receive varying thicknesses. By means of pins or punches attached to the rollers the glass may be perforated if required. Drawings are attached to the specification.—C. X. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland Cement. Candlot. Bull. Soc. d'Encouragement l'Ind. Nat. 1889, 212—229.

CANDLOT'S paper has been accepted by the chemical committee of the society through H. le Chatelier, of whose report the following is an abstract. The chief object of the author has been to examine the various methods of testing Portland cement, already in use. These are comprised in the determination of (1) chemical composition, (2) fineness, (3) density, (4) speed of setting, (5) tensile strength. Taking these *seriatim* we find :—

(1.) The ultimate composition of a cement may vary within tolerably wide limits without affording any criterion of quality. The only three points that can be thus used, are the percentage of insoluble matter, which in the case of cements of good quality does not exceed 1 per cent.; the loss on ignition (water and carbon dioxide), which if greater than 3 per cent., indicates that the cement has undergone sufficient alteration to appreciably diminish its strength; and the presence of sulphides in notable amount, which points to adulteration with blast-furnace slag.

(2.) Candlot considers that all particles which refuse to pass through a sieve with 900 meshes per square cm. are inert; those passing one of silk have a marked influence on the early stages of hardening, while those of intermediate size ultimately become hydrated and harden as perfectly as the finest, but take a considerable time in so doing. It therefore appears that this test is of value intrinsically, but it is also important on account of the bearing it has on others of the tests usually made, such a *density* and *speed of setting*.

(3.) A careful distinction must be drawn between absolute and apparent density; the former is that of an isolated particle, while the latter is the weight of a given measure of

the cement. The former varies within very narrow limits (3.108 for cement from under-burnt yellowish clinker, and 3.154 for that from well-burnt black clinker, being the extreme figures quoted), and is of little use in judging quality. The latter must obviously be taken under standard conditions of filling the measure, as otherwise enormous variations will occur. It is found that the apparent density increases with the coarseness of the sample examined, and it is this fact that has given rise to the fallacy that a low density is characteristic of an under-burnt cement; under-burnt cement is soft, and becomes more finely divided by a given amount of grinding than a well-burnt one, and it is this greater fineness that causes it to have a low apparent density. Density, real or apparent, is therefore dismissed as of but slight value.

(4.) An arbitrary method of determining the beginning and end of the setting is inevitable. Vicat's needle, which is a point 1 mm. in area loaded with 300 grms. is commonly used. The influence of various conditions and circumstances was studied.

- (a.) *Rise of temperature* much hastens the setting; the alteration is most marked with slow setting cements.
- (b.) Decreasing the *proportion of water* used for tempering quickens the setting; it is on this account that neat cement sets more quickly than when mixed with sand, because in the latter case more water is needed for a given weight of cement.
- (c.) Soluble *foreign salts*, such as calcium chloride, sulphate, and nitrate, retard setting; sodium chloride is without influence; sea water forms calcium sulphate and chloride by the action of the magnesium salts it contains on the lime of the cement, and therefore also lessens the speed of setting. Under-burnt cements are most affected in this respect.
- (d.) *Fine grinding* quickens the setting to a slight extent, more so with fresh than with sea water.
- (e.) *Exposure to air*, involving as it does the absorption of water and carbon dioxide, considerably retards the setting.

From this it appears that the speed of setting is so easily altered by comparatively slight causes that its determination is of little value as a means of judging the quality of the cement. Moreover, Portland cement of good quality may set in any time from 10 minutes to 10 hours according to its method of manufacture (the very quick-setting variety is, of course, specially made to replace ordinary quick-setting cements). The chief reason, therefore, for examining samples in this respect is to ascertain whether they be suited for the work in which they are to be used.

(5.) Tests in compression approach more nearly than those in tension to the conditions obtaining in practice, but are little used on account of the difficulty of making them and the costliness of the apparatus necessary. Candlot has confined his attention to tensile tests, and points out many sources of uncertainty. For instance, it is customary to make the tests in sets of six, and as the figures given by these often vary widely, to adopt certain arbitrary rules which may differ among themselves; thus some operators return the mean of the whole, others that of the three strongest, others again the highest value of the six. Further the tensile strength of the cement, whether neat or mixed with sand, is not the same per unit of sectional area for briquettes of all sizes; it appears rather to be proportional to the perimeter of the section.

The maximum strength of a cement is not usually reached until at least a year has elapsed after its setting; normally, the limit once reached is invariable; certain cements, however, show a retrograde tendency, especially such as contain an excess of lime or are under-burnt. Even a good cement, if very finely ground, mixed with sea water, and tested neat, will generally reach a maximum strength between the third and sixth month, but this is a phenomenon of a different order altogether, for it does not occur if the cement be mixed with sand or tested in compression. Candlot's figures show that the usual 7 and 28 days' tests fail to give any but an imperfect idea of the final strength of the cement.

The quantity of water used is without influence if it vary not more than 20 per cent. of its total amount; beyond this limit a decrease in strength occurs. There is usually a perceptible difference between cement mixed with soft and sea waters, but its direction and amount cannot be reduced to any rule. The influence of temperature on the final strength is doubtful, as is also that of the environment in which the briquettes are kept, *e.g.*, in moist or dry air, or under water. Cement ganged on an absorbent surface, such as a plaster slab, and left there for 24 hours before immersion, shows a much higher tensile strength than when a non-porous plate has been used, if tested after a fairly short period has elapsed; in the long run this difference tends to disappear. The kind of sand used and the proportion adopted are also noteworthy factors.

Besides all these, which are external conditions, and apply equally to good and bad cements, there are certain intrinsic properties of cements which influence its tensile strength. First with respect to the *composition*: an over-limed cement will show a high tensile strength to begin with, but will be apt to retrograde; if over-clayed on the contrary, it will be at first somewhat weak, but will not thus deteriorate afterwards. Secondly, *burning*: under-burnt cement of normal composition will set rapidly and attain its maximum strength in the first month. Thirdly, *fineness*: this is without influence on the final strength if the cement be tested neat, but if mixed with sand the finer cement will be considerably the stronger.

From these facts one is forced to conclude that the determination of the tensile strength does not define the quality of a cement with any great precision.

To supplement these methods of testing it has been proposed to allow the briquettes to harden under water at 80°–100° C., instead of at the ordinary temperature. This, Candlot condemns, but Chatelier is of opinion that it is useful, especially in discriminating between cements of really good and thoroughly bad quality; over-limed cements are detected by the deterioration they suffer.

Finally, Chatelier comments on the discouraging state of things indicated above, and suggests that reform is much needed in our methods of testing. It is of no interest to know the tensile strength of cement that is to be used in compression when no certain relation exists between the two. He lays down the following rules with which, among others, a cement of good quality should comply:—

- (1.) It should possess a fair but not necessarily high strength, when tested mixed with sand and in compression.
- (2.) It should be capable of adhering with sufficient firmness to ordinary building materials such as brick and stone.
- (3.) It should not disintegrate spontaneously or crack or swell.
- (4.) It should not disintegrate under the influence of perfectly dry air or frost.
- (5.) It should, if intended for marine work, resist the action of magnesium salts as far as possible.—B. B.

Basic and Fire-proof Stones from Basic Slag. Dingl. Polyt. J. 272, 17.

THE *Hüstener Gewerkschaft* (Hüsten, Westphalia) proposes as a binding material for basic and fire-proof stones the phenolates of the alkalis and alkaline earths (Ger. Pat. 46,237, Nov. 24, 1887), of which the phenols have been obtained by the dry distillation of coals, brown coal, peat, or wood. The tar from these materials is distilled, and the tar oils thus obtained are separated in the usual way into phenols and hydrocarbons.

The first (carbolic acid or creosotes) are then stirred to a thin paste with the alkali or alkaline earth selected. The mass becomes warm, and before it can cool and harden, the fire-proof materials are mixed with it. In a few hours the mixture hardens, and it must at once be brought into the desired position, and form just like cement. The purer the phenols employed, *i.e.*, the more carefully the neutral oils are removed, the harder and more durable is the moulded mass. Those materials, which in the roasted condition possess basic properties, *e.g.*, limestone, marble,

dolomite, magnesite, &c., may, after burning and suitably pulverising, be worked up with the phenols at once, to yield a plastic mass capable of being moulded, and which on cooling also hardens like cement.—W. S.

The Influence of Sugar on the Hardening of Cements.
Stammer. *Dingl. Polyt. J.* 271, 266—278.

A SERIES of experiments have been made on the influence of additions of sugar on the hardening of cements, by H. de Parsons and H. Hobart Porter on behalf of the American Society of Civil Engineers. The chief results obtained were that the addition of sugar or molasses delayed the setting of the mortar, the retardation being greater when molasses was used, but when certain proportions were not exceeded the strength of the mixture was greater than that of the pure cement. Less than 2 per cent. of sugar must be added to Portland cement, and less than 1 per cent. to Roman cement, otherwise the mortar will not hold together.

The following diagrams show graphically the results of the experiments. The abscissæ represent the duration of

Fig. 1.

Fig. 2.

Fig. 3.

the hardening in days, and the ordinates the breaking strain in kilos. The sugar appears to have no chemical action on the other materials, crystals of it being easily detected on the broken surfaces. The authors are of opinion that the increased binding power of the cement brought about by the addition of sugar is due more to mechanical than chemical causes, as the presence of the sugar retards the setting of the cement, and consequently favours the completion of the chemical reactions involved in that process.—W. M.

X.—METALLURGY.

Progress in the Iron Industry. W. Kuort. *Dingl. Polyt. J.* 272, 1—18.

A MODIFICATION of the Bessemer process by Carlsson (Sweden), which yields a product containing about 0.2 per cent. of carbon and 0.02 per cent. of silicon, is described.

—A. R.

Extraction of Zinc in Shaft Furnaces. W. Koyort. *Dingl. Polyt. J.* 272, 268—272 and 312—319.

THE extraction of zinc in shaft furnaces is a question which requires a satisfactory solution. For a number of years many attempts have been made to improve the shaft furnace process. In 1878, Binon and Granddils in Stolberg made the attempt to use a zinc oven with upright retorts. They aimed at making the old Cornithian method continuous. The materials containing zinc were heated with reducing agents by gas in reduction spaces in the form of shafts, which were filled above, and emptied below.

The zinc shaft furnaces of Henri Harmet have above and below an apparatus for leading off the zinc vapours. The volatile products are led through two long cylindrical upright chambers in which the reduction of carbonic acid to carbonic oxide, and traces of zinc oxide to metallic zinc is completed. Westman, in the year 1881—85, used two shaft furnaces supplied with coal, and one for preparing briquettes of ore and coal. Through both the first shaft furnaces generator gas was passed, by the combustion of which in the regenerating chambers sufficient heat was produced to reduce the ore to metal. Quaglio, Pintsch, and Lentz obtained, in the year 1884, a patent for a furnace construction which consists in the arrangement of two shaft ovens connected by a canal, into one of which the air is introduced, and from the other the products of the reaction are withdrawn, this constantly being reversed. The discoverers indicate that the principle of their discovery consists in reducing the carbonic acid into carbonic oxide, so that the apparatus forms at the same time a carbonic oxide generator, in which the units of heat formed by the combustion of carbon to carbonic oxide, otherwise lost, are made use of, and the carbonic oxide is used as a heating gas. Rigaud uses likewise a double shaft furnace. One shaft is upright, and is charged in the usual way with ore and fuel. The other has an inclined position, and is in combination with the first under the hearth; it is only charged with coal. Metallic vapours come off with the gases escaping from the hearth, oxides probably being reduced also. Its temperature is only so high that the metallic vapours are condensed, and the liquid metal runs down the side channels, and is collected in an outside receiver. Steger considers the preparation of zinc in shaft furnaces possible if enough heat is produced for the reduction, and the zinc produced led over in an atmosphere of carbonic oxide into the cooled receiver for condensation in the liquid form. Steger has tried to find out whether by regulating the air current, and the supply of coal, the percentage of carbonic acid in the gas may be reduced so low that its action is immaterial. One of the most important conditions for producing an atmosphere rich in carbonic oxide consists in securing the highest possible temperature in combustion, attained by means of a highly heated blast. With a blast temperature of about 1,200° C., only a trace of carbonic acid is formed with the carbonic oxide. Clerc uses a blast heated nearly to the melting point of iron on a cold mixture of zinc oxide and charcoal powder. The zinc is driven forward as zinc dust, and at first flakes of zinc oxide are formed. Steger recommends now, horizontal shaft ovens, a detailed description of which is given. In these furnaces the zinciferous material mixed with coal is added from above. The furnaces are then brought to a full red heat by a very hot blast, and then the coal reduces the zinc from its ores. The chief question now is how to obtain the least possible quantity of carbonic acid, and have all the oxygen of the blast converted into carbonic oxide. Continuous working is not possible with these furnaces. Horizontal ovens are also preferable for sanitary reasons.

Just recently a method of Eichorn's has appeared. Eichorn's method resembles Westman's in the choice of apparatus, but differs essentially in principle. Eichorn heats the oxides produced by the reduction of the carbonic acid again to a temperature sufficiently high to reduce them. (Berg-und Hütten. Zeit. 1888, Nos. 43 and 44.) For this purpose two shaft furnaces filled with coke are used, by which the temperature is produced by hot blasts. These coke furnaces serve to store up heat, and for reduction, while the Westman gas producers are only for condensation. Eichorn's method can be used not only for the production of zinc, but also all those metals and metalloids which are separated in the form of vapour from their compounds on account of their low boiling points.

A new method of reduction by aid of heat stored up before in the reducing carbon has been introduced with the water-gas process. Eichorn says that this cannot be used in connexion with the ordinary shaft furnace process, but can replace the process in which vessels are used in the furnace, as no vessels, less handwork, and less coal are used. Since the heat stored up in the coke is only limited, it must be renewed in a proportionally short time. The working should be in alternate periods of reduction (which is also a period of hot blast), and of storing up of heat, being charged every $\frac{1}{2}$ —1 hour. Practically this method can only be used for the reduction of gases, vapours, and solids in such fine clouds of dust that they are carried away with a stream of gas. Eichorn is now examining the applicability of this method to the preparation of sulphur from SO_2 , and zinc from finely-divided zinc oxide. If the behaviour of the oxygen compounds of these elements on being reduced with coal is compared, then the following numbers are produced by 1 kilo. of each substance:—

Compound 1 kilo.	Heat necessary for the decomposition of the compound.	Heat formed by burning the O of the compound from C to CO.	Difference of the two foregoing Nos.	Carbon combined with, by the oxygen of the compound.
Cal. H_2O	Cal. 3,222	Cal. 1,600	Cal. 1,622	Kilo. 0.0666
SO_2	1,110	900	210	0.3750
ZnO	1,043	355	688	0.1481

As a sufficient amount of heat is not produced by the combustion of the oxygen in the compounds, the requisite quantity must be supplied by burning coal in air. With the hot blast only the combustion of carbon to carbon monoxide comes into account, and 1 kilo. of carbon produces $2,400 - 824 = 1,576$ available cal., if the gases escaping have a temperature of 500°C . From this can be calculated the amount of carbon theoretically required as follows:—

1.6958 kilo. of C for 1 kilo. H_2O .
0.5082 " 1 " SO_2 .
0.5816 " 1 " ZnO .

or,

23.7412 kilo. of C for 1 kilo. H.
1.0164 " 1 " S.
0.7285 " 1 " Zn.

The lowest possible temperature of reduction for sulphurous acid and water vapour is about 500° . Since, however, with the production of water-gas only carbon monoxide, and not carbon dioxide, should be formed with the hydrogen, in the practical working the temperature must be about $1,200^\circ$. This temperature corresponds to the reduction temperature for zinc oxide, so that the relations are the same in the three cases. The apparatus for the decomposition of sulphur dioxide and zinc oxide is essentially the same as that for the decomposition of water vapour. It consists of a roasting or shaft furnace in which the ore is roasted or melted down; this is connected with the two shaft furnaces charged with coke, and these with a receiver for condensation. Apparatus of the same size as for the water-gas process is used. The carbon required for 1 kilo. SO_2 is shown by calculation to be 0.874 kilo. Lead, silver, and copper in the zinc ores can be obtained

by this process. Hänisch and Schroeder have recently succeeded in absorbing the sulphurous acid from the roasting furnace gases, and condensing it to liquid sulphurous acid free from water.—A. J. S.

The Influence of Copper on the Tensile Strength of Steel.

E. J. Ball and A. Wingham. Iron and Steel Institute Spring Meeting, 1889.

THE iron rich in copper was produced by melting pig iron, and then adding to the molten metal oxide of copper. The carbon and silicon acted as the reducing agents for the cupric oxide, and the copper was thus introduced into the iron by a "reaction" and not by simple solution. A metal was obtained of the following composition:—

Cu = 7.550 per cent., C = 2.720, Mn = 0.290,
Si = 0.036, P = 0.130, S = 0.190.

The metal was bright, white in colour, crystalline, and very hard, but it did not offer any great resistance to impact. Varying quantities of it were then melted down with the basic Bessemer steel previously mentioned. The products of these fusions were allowed to cool very slowly. Test-pieces, 1 inch by $\frac{3}{4}$ inch by $\frac{3}{16}$ inch, were then cut, and submitted to tensile tests in a multiple lever-testing machine, the test-pieces being first carefully annealed.

The following table shows the percentages of copper and carbon in the metals tested, and the results of the tensile tests of the various specimens:—

Test-Piece.	Copper.	Carbon.	Tensile Strength.
No. 1	Per Cent. .847	Per Cent. .102	Tons per Sq. In. 18.3
2	2.124	.217	36.6
3	3.630	.380	47.6
4	7.171	.712	56.0

The elongations observed, however, were as follows:—Test-piece (1), 10 per cent.; (2), 5 per cent.; (3), 5 per cent.; (4), showed no visible extension, or the extension was but very slight. It will be observed that the tensile strengths of the specimens containing copper are greater than those of the specimens in which no copper is present. Some of the specimens, comparatively poor in copper and carbon, appeared to forge fairly well, both cold and hot. The principal effect that the presence of copper appears to exert on iron and steel is to render it extremely hard. From a general consideration of the results of the experiments it would seem that within certain limits copper does not prejudicially affect the mechanical properties of steel.

The Manufacture of Basic Open-Hearth Steel. J. H. Darby.

Iron and Steel Institute Spring Meeting, 1889.

ONE experimental steel furnace used was of five tons capacity, and above the regenerator chamber of the "Batho type" there were no end blocks, gas and air being conveyed from the chambers in wrought-iron pipes lined with brickwork; the air was admitted at right angles to the gas-pipes and above them, so as to bring the flame well on to the metal. This furnace gave considerable trouble. Sufficient heat could not be obtained; the refractory material in the gas and air tubes often required repairs. This furnace was abandoned when it was proved that phosphoric pig could be manufactured into good soft steel by treatment on a dolomite hearth. The next work tried by the author was that of designing and then building four 12-ton and afterwards two 20-ton furnaces. Each furnace was provided with a separate chimney, ordinary butterfly reversing valves of ample size, and regenerator chambers of large capacity. The furnace proper is composed of two wrought-iron sides, supported by H iron buck-staves, well braced together at the top and bottom. The ends are left open; holes are cut in the plates for the three doors on the front side of the

furnace, and another hole is made at the back for the tap-hole plates. The plates are also cut away to allow air to circulate for cooling purposes under the furnace bottom and bridge plates. The silica blocks at each end of the furnace are built in the usual manner. The roof is level from block to block; the ends, however, are well inclined to bring the flame down on the metal. On the iron plates for holding the dolomite hearth fire-bricks are placed, so that no part of the basic hearth when finished is more than 15 inches thick. As soon as all the brickwork is dry, hard burnt dolomite, well ground and mixed with a little anhydrous tar as will make it stick together when compressed, is rammed with hot irons until the desired shape of the hearth is built up; the tap-hole is made by a round piece of wood, which is left in and burnt out as the furnace heats up. The shrunk dolomite or basic material is brought up to the bottom of the doors and to an equal height all round. On it a layer of about two inches of chrome ore, also ground fine and mixed with tar, is rammed to act as a neutral separator between the acid and the basic portions; chrome ore is also rammed in between the silica blocks and the basic hearth. The side walls and jambs are built on the chrome ore. The roof is then put on and the furnace heated up, at first with a coal fire. When the furnace is properly dried and heated the hearth will become very hard; the tap-hole should be cleaned out and then filled with dry, ground, basic material for several inches. This should be well pushed up against a scraper held from the middle door. Anthracite coal is then rammed in, and the outside of the tap-hole is covered with damp sand. The charge may now be introduced. The author uses 80 per cent. of pig and 20 per cent. of scrap. Limestone is usually charged in sufficient quantity to make a basic slag from the first scrap and pig follow. When sufficiently hot, additions of iron ore and limestone are made at intervals during about five hours. The first sample is taken, and from its appearance and fracture it is judged if sufficient ore has been added. If so, as much as possible of the unspent oxide is reduced in the slag by reacting on the remaining impurities, lime additions being made from time to time. The hammered sample rapidly improves. The edges which were rough at first become smooth and free from cracks; the surface of the sample is clean, and when the charge is ready it will bend over into four thicknesses without any indication of cracking. Ferro-manganese is then added and the charge is tamed. Any kind of iron ore may be used in the steel furnaces, providing it contains a low percentage of silica. The 20-ton furnaces make from 180 to 200 tons of ingots per week, or 23·3 cwt. per hour, exclusive of Sundays. After experience in the manufacture of over 60,000 tons of basic open-hearth steel, the author has never seen red, short material in the usual soft quality. An average analysis of the soft steel is as follows:—

C = ·12 per cent., P = ·03, S = ·018, Si = nil, Mn = ·400.

This steel gives about 24·5 tons tensile strain per square inch and 15 tons elastic limit, with an elongation of 31 to 33 per cent. in eight inches.—A. J. S.

Alloys of Nickel and Steel. J. Riley. Iron and Steel Institute Spring Meeting, 1889.

THE author has shown that the composition of the alloy can be as effectually controlled in the open-hearth furnace as in the crucible. It can be made in any good open-hearth furnace working at a fairly good heat. The charge can be made in as short a time as an ordinary "scrap" charge of steel—say about seven hours—and its working does not demand so much care as is required in working many other kinds of charges. If the charge be properly worked, nearly all the nickel will be found in the steel, almost nothing is lost in the slag. The ingots are clean and smooth in appearance on the outside, but those richest in nickel are a little more "piped" than are ingots of ordinary mild steel. Any scrap produced can be re-melted in making another charge without loss of nickel. No extraordinary care is required when reheating the ingots for hammering or rolling. If the steel has been properly made, and be of correct composition, it will hammer and roll well, whether it contains little or much nickel. Some tables of tests of

steel with varying contents of nickel are given. In one case the addition of 4·7 per cent. of nickel raised the elastic limit from 16 up to 28 tons, and the breaking strain from 30 up to 40·6 tons, without impairing the elongation or contraction of area to any noticeable extent. In another case somewhat similar results were found with an addition of only 3 per cent. of nickel, combined with an increase of the carbon to 0·35 per cent. In two cases, one containing 2·0 per cent. of Ni, 0·90 per cent. of C, and 0·50 per cent. of Mn, the other 4·0 per cent. of Ni, 0·85 per cent. of C, and 0·50 per cent. of Mn, there was extreme hardness, due in part to the large quantity of carbon present, but also to the presence of nickel in addition. The quality of hardness obtains as the nickel is increased, until about 20 per cent. is reached, when a change takes place, and successive additions of nickel tend to make the steel softer and more ductile, and even to neutralise the influence of carbon. In the 25 per cent. nickel steel there are some peculiar and remarkable properties. In the unannealed specimen the breaking strain is high and the elastic limits moderately so, but in the annealed piece, while the breaking strain remains good, the elastic limit is very greatly reduced down to one-third of the breaking strain. Again, in both cases, the ductility as shown by the extension before fracture is marvellous, reaching 40 per cent. in 8 inches. Another feature is that this elongation is nearly uniform throughout the piece. The whole of the series of nickel steels up to 50 per cent. nickel take a good polish and finish, with a good surface, the colour being lighter with the increased additions of nickel. The steels rich in nickel are practically non-corrodible, and those poor in nickel are much better than other steels in this respect. The 1 per cent. nickel steel welds fairly well, but this quality deteriorates with each addition of nickel. The 25 per cent. nickel steel, with its peculiar properties of high breaking strain, great ductility, and comparatively low elastic limit, is extremely well adapted for all operations involving considerable deformation—for instance, for deep stamping and flanging—whilst its non-corrodibility will render it invaluable for a great number of purposes. In the region between 25 per cent. and about 5 per cent. of nickel are an abundance of possibilities as yet comparatively unknown, in which I expect will be found materials for tool steel equal, if not superior, to anything at present known.—A. J. S.

PATENTS.

Improvements relating to the Extraction of Aluminium from Substances containing the same. C. Netto, Dresden, Germany. Eng. Pat. 4228, March 21, 1887. 11d. (Amended Specification.)

IN the previous specification (this Journal, 1888, 217) the inventor states that "the decomposition commences at once and is completed in a few moments." He now substitutes the word "minutes" for "moments." Also, in the sentence "After the decomposition is terminated, the aluminium is never united into a coalescent lump" the word "never" is replaced by "seldom."—O. H.

Improvements in the Amalgamation of Gold and other Ores, and in Apparatus employed therein. A. E. Donkin, Rugby. From R. Donkin, Thames, New Zealand. Eng. Pat. 8303, June 6, 1888. 6d.

THE invention consists of a method for producing a constant supply of sodium amalgam, and bringing this in contact with the ore to be treated. At the bottom of a suitable non-conducting cell a layer of quicksilver is placed, which forms the electrolytic cathode. Above the quicksilver is poured a saturated solution of a sodium salt—preferably chloride of sodium—and into this is placed a carbon anode. The quicksilver and the carbon are connected to the terminals of a dynamo, or other suitable appliance for generating a current of electricity, so that, on the passage of the current, chlorine is liberated at the anode and sodium at the cathode. The sodium amalgamates with the mercury, and by making holes and fixing pipes in the sides of the cell below the level of the mercury, it may be connected

directly with the main body of mercury in an amalgamator, settler, or amalgamating pan. By a suitable contrivance the mercury may be made to circulate so that a regular supply of the sodium amalgam is distributed.—H. S. P.

Improvements in Plating Metals with Aluminium and Producing Alloys therefor. L. Q. Brin, Paris, France. Eng. Pat. 8746, June 14, 1888. 6d.

A COMPOSITION is made by fusing alumina or a clay rich in alumina with about half its weight of borax, finely powdering the mass so obtained, and mixing it with oil or water. The metal articles to be coated are cleaned with acid, coated with this paste, dried and heated in a reverberatory furnace until the material of the coating is melted. It is stated that aluminium is thus set free, and that it unites with the surface of the metal and spreads thereon as tin in the operation of tinning.

A reducing atmosphere of nitrogen, cyanogen, carbonic oxide, or preferably of ammonia, is employed, by which means it is also maintained that "the retort or apparatus wherein the ammonia is generated also serves as a condensing chamber for the surplus aluminium vapours generated in excess from the heated flux, which vapours in the presence of the nascent ammonia become reduced to the metallic state. This pure metal is therefore collected at the same time as the operation of making the alloys, and can be employed for enriching the alloy or for other purposes."—A. W.

An Improved Process of Producing Aluminium Bronze and other Alloys of Aluminium. L. Q. Brin, Paris, France. Eng. Pat. 8747, June 14, 1888. 6d.

PIECES of metal, such as copper, steel, or iron, &c. are first "moistened with water," then mixed with a quantity of aluminium hydrate or rich aluminiferous clay, borax, and salt, and melted in refractory crucibles. It is stated that aluminium bronze or steel is produced. The operation is accelerated by passing into the crucibles reducing gases, such as ammonia, &c. "in the nascent state."—A. W.

Improvements in the Manufacture of Sodium and Potassium. W. G. Forster, London. Eng. Pat. 9391, June 27, 1888. 4d.

INSTEAD of using solid carbonaceous matter to reduce caustic soda or potash the patentee introduces coal gas or carbonaceous vapour or other reducing gas or vapours through a perforated pipe immersed in the fused alkali. The metal is distilled over and condensed in the usual way.—H. S. P.

Improvements in Tempering or Hardening Steel and Iron. G. Theodossieff, St. Petersburg, Russia. Eng. Pat. 9457, June 28, 1888. 6d.

GLYCERIN is used in tempering steel, cast steel or cast iron. The specific gravity of the glycerin may be varied between 1.08 and 1.26 at 15° C. by adding water, according to the composition of the steel. The quantity of glycerin should be from one to six times greater in weight than the weight of the pieces to be plunged in it, and its temperature may be varied from 15° to 200° C., according to the hardness of the metal. The harder the steel to be tempered the higher should the temperature be, and for a mild steel a low temperature should be used. To increase the quenching power of the bath, various salts may be added to the glycerin solution. Thus, when a hard temper is wanted, proto-sulphate of manganese may be added in quantity varying from 1 to 34 per cent. of the liquid, or from $\frac{1}{4}$ to 1 per cent. of sulphate of potassium. For a softer temper 1 to 10 per cent. of chloride of manganese and 1 to 4 per cent. of chloride of potassium may be added. The principal advantages to be derived from these methods are—(1.) The temperature of the aqueous solutions of glycerin may be varied within wide limits, the boiling point of pure glycerin being 29° C. (2.) Owing to the fact that solutions

of glycerin in water dissolve most salts that are soluble in water, its quenching properties may be readily varied, by dissolving such salts in the bath, to suit the kind of metal to be tempered, and the degree of temper required.—H. S. P.

Improvements in the Manufacture of Aluminium and its Alloys. J. A. Stephan and R. Southerton, Birmingham. Eng. Pat. 10,266, July 16, 1888. 6d.

"EMERY Alum Clay" or any other material rich in alumina, such as a mixture of emery and an alum, preferably ammonia alum, is heated in a crucible, and a current of hydrofluoric acid gas passed through it. When the mass has changed from the spongy to the pasty state, the current of gas is stopped, and the temperature raised till the metal flows.

If four parts of a mixture of equal quantities of emery and ammonia alum be added to 100 parts of hematite iron ore, and the whole melted in the blast furnace in the usual manner, "aluminium pig steel" is produced.—A. W.

An Improved Method or Process of Covering Articles of Iron with Lead. W. R. Lake, London. From Velthuisen and Co., Frankenthal, Germany. Eng. Pat. 11,022, July 30, 1888. 6d.

THE article of iron or steel is first cleaned (preferably by steel brushes), then roughened by a sand-jet blower, washed over with a soldering liquid, and plunged into a bath of molten lead. While in the bath the article is brushed with steel brushes to ensure intimate contact between the lead and the iron. The layer of lead thus obtained is too thin to protect the iron from the action of acids, and the article is subjected to a second operation. If it be a plate of iron or steel it is fixed horizontally, with a narrow rim or border placed round it, and it is then washed over with soldering liquid, heated to about 400° C., and molten lead is poured over its surface and uniformly distributed. The height of the rim determines the thickness of the layer of lead. The whole is then again heated to a temperature above the melting point of lead, and the surface again brushed with steel brushes. The plate is then allowed to cool, care being taken during the cooling of the sheet iron or plate to keep the layer of lead as long as possible above the melting point of lead, by fresh additions of small quantities of molten lead. In the case of articles such as pipes, boilers, or similar vessels, a suitable "core" or easing is provided, and after treating the surface with soldering liquid and heating to 400° C., the space between the article and the "core" is filled with molten lead. The whole is then again heated above the melting point of lead, and finally allowed slowly to cool, the lead again being kept as long as possible in a molten state.—H. S. P.

Improvements in the Utilisation of Waste Pickle from Tinning and Galvanising Works where Hydrochloric Acid is used for Pickling. H. J. Kirkman, Swansea. Eng. Pat. 16,247, November 9, 1888. 6d.

THE iron is precipitated from the waste liquor, previously rendered clear, if necessary, by subsidence or filtration, by means of lime, limestone, chalk, gas liquor, ammonia, sodium hydrate or sodium carbonate. The precipitated iron is washed and dried and may then be ignited for making pigments, or mixed with sawdust for purifying gas.—E. E. B.

A Process for Decomposing Commercial Nickel and its Salts and Galvanically Coating Objects with pure Nickel. G. Krüss, Munich, Germany. Eng. Pat. 1418, January 25, 1889. 6d.

As a result of his researches the patentee finds that metallic nickel contains on an average only about 98 per cent. of real nickel and 2 per cent. of another element, irrespective of the known technical impurities, which differs from nickel in its properties and in the nature of its compounds. This element he designates "X" in the specification. It is impossible to purify the nickel in one operation, as the combinations of X are soluble in nickel salts. It is necessary

to repeat several times one or more of the operations based upon the following behaviour of the neutral chloride of the element X:—(1.) It gives a combination with alkali soluble in water when treated with concentrated alkali lyes or melted with caustic alkali. The white hydroxide, however, is very slightly soluble in excess of weak alkali. (2.) It is incompletely precipitated by oxalic acid either hot or cold, but more completely by oxalate of ammonium after short standing at a low temperature. A large excess of the latter precipitant redissolves the precipitate. (3.) It is not precipitated by fixed alkali lyes, ammonia, ammonium oxalate, or oxalic acid, even at high temperatures, if the solution contains organic acids, such as acetic, citric, &c., whereas the soluble double oxalate of nickel is decomposed on heating under the same conditions. Again, when the solution of X is brought into contact with a metal more electro-positive than nickel, such as zinc, it is not reduced even on warming. These properties are all more or less altered or concealed in the presence of a large excess of nickel salts. Thus the white hydroxide of X is not precipitated at all by ammonia if more than 70 per cent. of the dissolved substance consists of nickel salt.

To separate nickel from X the neutral solution is mixed with ammoniacal oxalate of ammonium till the precipitate is redissolved, and is allowed to stand for some time, whereby white basic oxalate of X is precipitated. Repeated additions of ammoniacal oxalate of ammonium are made at intervals until after long standing no more precipitate is produced. The blue liquid is then evaporated, the residue ignited and dissolved in hydrochloric acid. The chloride solution is concentrated and solid caustic soda, up to five times the weight of chloride present, is added, the pasty mass being kept melted for a short time. When cold it is broken up and dissolved in small pieces in ice-cold water, care being taken that the temperature does not rise above 10° C. The sodium compound of X is dissolved while the nickel remains insoluble. After decanting and washing, the residue is dissolved in a weak mineral acid or in acetic acid, a quantity of citric or other organic acid is added, and, after heating, the pure hydroxide of nickel, free from X, is precipitated with soda solution; or the pure oxalate of nickel may be produced by precipitating the boiling organic acid solution with ammonium oxalate.

In lieu of this, however, the original solution, or any of the solutions produced above, may be decomposed and pure nickel obtained by warming with zinc dust or cuttings. The necessity of repeating any or all of the above treatments is regulated by the quantity of X originally present.

The purified nickel is well suited for nickel plating, as it gives a coating lighter in colour and more like silver than that heretofore obtained, which is generally of a brownish-yellowish hue, owing to the presence of the so-called element X.—A. W.

Improvements in the Manufacture of Metal Alloys. S. McColley Godfrey, New York, U.S.A., and J. B. Allen, London. Eng. Pat. 2031, February 5, 1889. 6d.

THE idea is to produce the metal to be alloyed from its ore in the same crucible and by the same operation as that in which the alloy is made. The ore of one metal is placed in a crucible, covered with a flux, and the other metal is poured on to this, whereby the first metal is reduced and alloys "in a uniform manner" with the second.—A. W.

Improvements in the Treatment of Steel. C. Jones, Derby. Eng. Pat. 4956, March 21, 1889. 4d.

STEEL scrap (e.g., railway-carriage and other carriage springs) after being cleaned by immersion in dilute sulphuric acid and subsequent washing in boiling water, are dipped first into oil or grease and then into soot. The scrap is then packed with powdered gas coke in a metal box, and heated in a furnace for 30 hours or more, at about 1,400° F., then withdrawn and allowed to cool slowly. The scrap may then be melted into blocks or ingots which can be rolled, welded, hammered or otherwise treated in the usual way.—H. S. P.

Improvements in the Manufacture of Ingot Iron or Steel and the Simultaneous Production of a highly Phosphoric Slag. J. H. Darby, Brynbo. Eng. Pat. 5667, April 2, 1889. 4d.

IN the basic open-hearth process of steel-making, instead of introducing limestone along with the charge, as is usual, the patentee introduces a quantity of slag from a previous charge. He finds by experiment that, to 10 tons of metal, consisting of 7 tons of phosphoric pig and 3 tons of scrap, about 10 cwt. of slag is a suitable quantity to add. When this is melted the additions are made in the usual way, except that instead of introducing limestone with the iron ore, a further addition of slag is made. The process is then continued to completion with limestone and iron ore or limestone additions alone. It is not generally necessary to use lime, as the slag on the surface is usually sufficiently basic from the beginning of the operation. The furnace linings, &c., are therefore not cut away by lime dust so rapidly as when lime additions are made, and the resultant slag is richer in phosphoric acid than ordinary basic slag.

The purification of pig iron and simultaneously of ferruginous phosphatic slag has already been patented by Fwynham (Eng. Pat. 1796 of 1886; this Journal 1887, 43), and the inventor makes no broad claim to the use of the principle involved, but only so far as regards the method of procedure above described.—H. S. P.

Improvements in the Production of Aluminium. C. M. Hall, Oberlin, Ohio, U.S.A. Eng. Pat. 5669, April 2, 1889. 8d.

THE fluorides of aluminium and calcium are melted in a carbon-lined crucible, alumina is dissolved in the fused mass, and the whole then submitted to a current of electricity. Carbon electrodes are used, or if an alloy be required the negative electrode is made of the metal to be alloyed. Any alkaline earth fluoride can be used, and sodium fluoride and calcium chloride may also be added to the bath. The best mixture is that which corresponds to the formula CaAl_2F_6 . The advantage of continuity is obtained by replenishing the bath with fresh additions of alumina.—A. W.

Improvements in the Production of Aluminium and Alloys thereof. C. M. Hall, Oberlin, Ohio, U.S.A. Eng. Pat. 5670, April 2, 1889. 8d.

THIS specification is similar to the above except that the double fluoride of aluminium and potassium or sodium is used as the bath in which to dissolve the alumina. In this case any alkaline earth fluoride may be present, and it is stated that the presence of lithium fluoride in the bath increases its power of dissolving alumina.—A. W.

Manufacture of Compressed Compound Blocks of Substances containing Iron and Carbonaceous Matter and the use of such Blocks in the Production of Cast Steel and Ingot Iron. L. Imperatori, Milan, Italy. Eng. Pat. 7132, April 29, 1889. 6d.

IRON ores, iron oxides, slags rich in iron, &c., are reduced to powder and mixed in suitable proportions with ground charcoal, coke, or anthracite, and the mixture is moistened with water, well stirred to render it uniform, and then stamped or pressed in moulds, into blocks. These blocks, after drying, may be melted in a reverberatory furnace to produce ingot iron or cast steel, or they may be used in the Martin process. Directions are given as to varying the composition of the blocks, to suit the kinds of ores used and the manner of smelting employed.—H. S. P.

Improved Method of and Apparatus for Condensing Zinc Vapours and Collecting the Metallic Zinc therefrom. E. Walsh, St. Louis, U.S.A. Eng. Pat. 7181, April 30, 1889. 8d.

IT is known that the temperature at which zinc oxide reduces is about 1,300° F., while metallic zinc distils at a temperature about 100° lower. In the metallurgical process of making zinc in a cupola furnace, the zinc vapour passes from the furnace mixed with a considerable quantity of carbonic acid, which, at the temperature of distillation, has an oxidising

effect upon it. The patentee has found that carbon has no effect upon carbonic acid at temperatures lower than 1,300° F., but at temperatures between 1,400°—1,500° carbon converts carbonic acid into carbonic oxide, which has no action upon zinc vapour. By passing the mixture of carbonic acid and zinc vapour, heated to between 1,400°—1,500° F., over carbon the carbonic acid is converted into carbonic oxide, and the whole of the zinc may be condensed in a cooler part of the apparatus. The apparatus described in the patent consists of a eupola furnace near the top of which a condensing chamber projects. This chamber consists of a round flue, and it is filled with the carbonaceous matter required to reduce the carbonic acid. The carbon is fed in through a hopper or opening near the cooler end of the condenser, and it is forced along the condenser by a plunger or a suitable screw arrangement. The zinc which distils falls through perforations in the cooler part of the condenser and is collected in a trough placed below. Drawings are given with the specification.—H. S. P.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

On the Difference of Potential at the Contact of a Metal with Salt of the same Metal. H. Pellat. *Compt. Rend.* 108, 667—669.

WHEN a metallic liquid, such as mercury, is allowed to flow into an electrolyte, a current is generally obtained when connexion is made by means of a wire between the metal which is flowing out and the metal of the same kind which has collected at the bottom of the vessel. If the former is insulated it very soon attains a fixed potential which sometimes differs considerably from the potential of the metal which is at rest at the bottom of the vessel; thus, in the case of mercury flowing into a solution of zinc sulphate, this difference of potential is equal to 0.52 volt. It can be measured by the usual compensation method, using a potentiometer and Lippmann's capillary electrometer. The author assumes that the quantity thus measured represents what he calls the normal difference of potential between the electrolyte and the metal which is at rest, and deduces from his experiments the following results:—

(1.) *The normal difference of potential between a metal and a solution of a salt of the same metal in contact with it is zero.* The metals employed were mercury and the fluid amalgams of copper and of zinc. These latter behave in a voltaic cell exactly like solid copper and zinc. Thus a cell consisting of amalgams of copper and of zinc in a solution of zinc sulphate has an E. M. F. of 0.985 volt; a Daniell cell consisting of sulphate of zinc, sulphate of copper, and amalgams of these metals, has an E. M. F. of 1.063 volt. But no difference of potential appears to exist between mercury and nitrate of mercury; and the largest difference of potential observed between a metal and its salt (in the case of zinc amalgam and zinc sulphate) was only 0.002 volt.

(2.) If we denote by P, M, and M' the metals which form the poles and each of the electrodes of a cell of the Daniell type, and by S and S' the salts of these metals in contact with them (salts of the same acid), then the E. M. F. of the cell necessarily is—

$$E = P | M + M | S + S | S' + S' | M + M' | P.$$

But by Volta's law $M' | P + P | M = M' | M$; and according to the law stated above (1) we have $M | S = S' | M' = 0$.

$$\text{Hence } E = S | S' + M' | M, \text{ or—}$$

The E. M. F. of a cell of the Daniell type is equal to the difference of potential of the two liquids in contact together with the difference of potential which would exist between the two metals forming the electrodes, if these were placed in direct contact.

Again, the E. M. F. of such a cell is proportional to the quantity of heat produced by the substitution (in a salt of the same acid) of the metal forming the anode instead of the metal forming the cathode. Therefore the difference of potential due to the contact of two metallic salts of the same acid, plus that due to the contact of the metals themselves, is proportional to the quantity of heat set free in the substitution of one of the metals for the other in a salt of the given acid.—D. E. J.

The Elmore Copper Depositing Process. Electrical Review, 24, 682.

THE process consists in depositing the metal from a copper sulphate solution upon a rotating mandril, a burnisher of agate having a few pounds pressure being in continual operation from one end of the cathode to the other. The effect of the burnisher on the physical character of the copper is remarkable, a very high tenacity and great malleability being imparted to the deposited metal. Wire is made from the copper cylinders by cutting from them spirally a continuous square strip, which is then drawn directly to the required diameter without remelting. The wire so obtained, compared with the usual standards, has an electrical conductivity of 102 per cent.—W. W. H. G.

PATENTS.

Improvements in Gas Batteries. L. Mond, Northwich, and C. Langer, London. Eng. Pat. 2411, February 17, 1888. 8d.

To overcome the difficulties incident to the old forms of gas batteries the use of a simple liquid electrolyte is abandoned in favour of a solid porous material which is impregnated with some liquid electrolyte. Plates of porous earthenware and plates of plaster of Paris have been found to be the most suitable absorbents. The porous substance used is brought into contact with the material, such as platinum black, having the power of occluding gas. Connexion between the poles of the battery and the occluding material is made by the help of very thin platinum, or gold foil or leaf perforated by very numerous and very small holes. The prepared plates are fixed in gas-tight chambers through which gases can be passed. When the gases are such as hydrogen and oxygen, which produce water on combination, it is advisable to employ them dry or hot so that the platinum black, or whatever occluding substance is used, may not become moist, which would have the effect of greatly diminishing the action of the battery. When hydrogen and atmospheric air are used it is found that all the water formed can be removed by simply passing an excess of air through the battery without previous drying or heating. By using at one plate of the battery air and at the other side "hydrogenic gases," produced by the action of steam upon incandescent coke, anthracite, iron, or in other ways, electricity may be produced at a very low cost. It is, however, very necessary to have the gases carefully purified and freed as much as possible from carbon monoxide. It is claimed that even when using hydrogen produced by the action of sulphuric acid on zinc these new gas batteries offer special advantages over ordinary galvanic batteries. The actual construction of the batteries differs in detail in accordance with the size desired, but the general principle followed will be understood from the figure which represents

the section of a very small battery consisting of a single plate of porous material M. This is fixed in a non-conducting frame (such as ebonite) R R by means of cement S¹ S. On both sides of the frame are narrow conducting strips A A which are joined to the battery terminals. The porous plate M having been impregnated with dilute sulphuric acid, is covered on both sides with the platinum or gold foil m m. This projects beyond the plates in such a way that it is in metallic connexion with the conducting strips A A, which are properly protected from the action of the electrolyte by paraffin or varnish. The perforated foil is made to adhere to the porous plate by gently rubbing over its surface, and is then covered with platinum black obtained by the reduction of platinum chloride in dilute alkaline solution by means of formic acid. Only about 0.2 gram. of the Pt. per sq. dem. of surface is required to give a good result. The platinum black is formed in a paste with dilute sulphuric acid, and then applied with a brush. Part of the black penetrates through the holes of the foil, and is hence in contact with the porous plate. To form narrow gas-tight cells G G¹, plates of india-rubber K K, and the end plates E E are used, which are held in place by the bolts E¹ E¹. The chambers G G¹ are put in communication with the gas-conducting tubes O O and H H. The chemical action consists in the decomposition of the sulphuric acid into, say, H₂ and SO₄. The hydrogen appears at the oxygen side and there, under the influence of the platinum black, forms water. The SO₄ travels to the hydrogen side, where sulphuric acid is again produced. To counteract the tendency of the accumulations of water and sulphuric acid it is advised to reverse from time to time the places of the oxygen and hydrogen.—W. W. H. G.

Improved Method or Process for Depositing Metals from their Salts. W. H. Beck, London. From A. Lévy, Paris, France. Eng. Pat. 8961, June 19, 1888. 6d.

The process consists in hanging the metal article, say of iron or copper, by means of a zinc wire in an acid or alkaline solution of the salt of the metal to be deposited, preferably the chloride or a double chloride; or the article to be coated may be placed in a rotating open-work box or cage of zinc or containing zinc immersed in the solution of the metallic chloride. Wire may be coated by causing it to pass over zinc pulleys immersed in the solution, or the salt, preferably the chloride, may be used. The specification states that the process is specially adapted to the deposition of aluminium and magnesium.—H. S. P.

Improvements in the Reduction of Zinc Oxides. C. A. Burghardt, Manchester. Eng. Pat. 9886, July 7, 1888. 6d.

The object of the patent is to obtain a pure quality of zinc free from the impurities contained in ordinary zinc, such as iron and manganese. The process consists in depositing the zinc from a solution of zinc oxide in caustic soda, by means of an electric current. The anodes and cathodes are of pure zinc, and are placed in a tank or cistern divided by porous partitions into compartments, so that each compartment contains, in alternate order, an anode or a cathode. The tank is filled with the alkaline solution of zinc oxide, and into each anode-compartment an excess of zinc oxide is placed. On passing a current of electricity the zinc may be deposited upon the zinc cathode while fresh oxide is taken into solutions at the anode, so that by keeping up the supply of oxide the operation may be continued until the accumulation of the impurities from the oxide or the formation of sodium carbonate (from the air) interferes with the action of the cells. The specification also provides for the agitation or circulation of the liquid if needed, or for its heating by a steam coil or otherwise, as for instance by the use of a hollow anode, through which steam may be passed, or by making a steam coil the anode.—H. S. P.

Improvements in and Apparatus for obtaining Copper and other Metals from Solutions of the Salts of same. W. P. Thompson, Liverpool. From A. Rovello, Turin, Italy. Eng. Pat. 12,208, August 24, 1888. 8d.

A series of Daniell's cells on a large scale are constructed by dividing the vats by means of vertical porous diaphragms, and in which the electro-negative elements consist of cast or wrought iron plates instead of zinc, unless zinc sulphate is a desideratum. The copper liquor is poured in a continuous stream through a funnel to the bottom of the compartment containing the copper cathode, and a weak solution of a salt of the same metal as the anode is simultaneously run into the compartment containing the anode. The two plates are connected by a metallic rod, electrical action takes place, and the copper solution is deprived of its metal in its passage upwards from the bottom to the top of the tank. Any arrangement can be used, but drawings are given of an apparatus which ensures a small internal resistance. The same can be used for the electrolysis of zinc solutions, in which case the cathodes are zinc plates, the anodes, iron, and the pole rods are connected with a dynamo. The advantage in the case of copper is the small consumption of iron as compared with the present precipitation process.—A. W.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Specific Gravity of some Fats and Oils. C. A. Crampton. Amer. Chem. J. 11, 232—236.

THE author has determined the specific gravity and co-efficient of expansion of a number of fats and oils, of which the following are the results:—

Description.	Mean Coeff. of Expansion Absolute.	Calculated.			
		Sp. Gr., $d = \frac{+15.5^\circ}{+4^\circ \text{ C}}$ Apparent.	Sp. Gr., $d = \frac{+40^\circ}{+4^\circ \text{ C}}$ Apparent.	Sp. Gr., $d = \frac{+50^\circ}{+4^\circ \text{ C}}$ Apparent.	Sp. Gr., $d = \frac{+100^\circ}{+4^\circ \text{ C}}$ Apparent.

—J. W. L.

A New Product of the Soap Industry. R. Meyer. Mittheil. des K. K. Tech. Gew.-Museums, 1889, 55.

A NEW product, known as "soap meal," made by O. Korschelt of Zittau, was analysed, with the results given below:—

	Per Cent.
Fatty anhydride	84.20
Soda	9.66
Sodium chloride, sodium sulphate, lime	3.26
Water (directly determined = 2.08)	2.88
	100.00

The soap appears as a yellowish-white powder, dry to the touch, easily soluble in water. It is quite free from uncombined alkali or fat.—E. B.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

PATENTS.

Improvements in the Treatment or Preparation of Paper, Cardboard, Paper-pulp, Papier Maché, and other Fabrics and Metals, to render the same impervious to the Action of Acids, Water, Air, Mineral Oils, and other Liquids or Gases. G. D. Aria, London. Eng. Pat. 8981, June 19, 1888. 6d.

See under XIX., page 565.

An Improved Varnish-removing Compound. E. Oates, Paris, France. Eng. Pat. 10,301, July 16, 1888. 6d.

TWENTY lb. of solution of caustic soda of 40° B., 1 lb. of potato starch, and 20 pints of water are introduced into a closed boiler. The mixture is thoroughly agitated, which effects spontaneous heating of the same with conversion into a gelatinous mass. This is treated with 57½ pints of water and 1½ lb. of potato starch to form a total weight of 100 lb. of final product. This composition constitutes the most concentrated type of varnish remover, and may be reduced with water to any desired percentage of alkali if required.—D. B.

An Improved Paint-removing Compound. E. Oates, Paris, France. Eng. Pat. 10,365, July 17, 1888. 4d.

THE paint remover is prepared by introducing 50 lb. of caustic soda solution of 40° B. and 8 lb. of Iceland moss into a closed boiler, and after thorough stirring, heating the liquid gently to boiling, at which point it is maintained for an hour. When completely cold, 100 lb. of caustic potash are added to the mixture, which is then again heated up to boiling. It is now left to cool, and treated with a quantity of potato starch in the proportion of from 6 to 8 per cent. of the mass.—D. B.

Improvement in the Production of White Lead or Carbonate of Lead, and the Apparatus therefor. R. W. E. MacIvor and F. A. Darlington, London; G. Paul, Edinburgh; and J. Allan, London. Eng. Pat. 10,426, July 18, 1888. 6d. (Amended Specification.)

LEAD oxide is mixed with a solution of an alkaline acetate (preferably ammonium acetate), and carbon dioxide driven

through the mass. White lead is formed which, when the action is complete, can be filtered off and the solution of the alkaline acetate used in effecting the conversion of a fresh quantity of lead oxide.

The chief alterations in the specification are the insertion of the names of co-patentees, and the withdrawal of the claim to use compounds of lead other than the oxide (this Journal, 1888, 846).—B. B.

Improvements in Anti-corrosive Compositions and Materials for Ships and other Structures, and in the Method of applying the same. R. Turnbull, Newcastle-upon-Tyne. Eng. Pat. 10,601, July 21, 1888. 6d.

THE object of the patent is to prevent corrosion in the holds and ballast tanks of iron and steel vessels. A coating of "paraffin" or "spirits of naphtha," Trinidad pitch, marine or fish glue, or one of shellac varnish, or of a varnish composed of Stockholm pitch and solvent "naphtha," is first applied cold; it is followed by one of asphaltum "tempered with Stockholm pitch and coal tar, marine glue, and paraffin wax," applied hot; the surface is then covered with calico, linen, or tough paper, which adheres to the last coating and prevents the succeeding one running into it; this latter is composed of asphaltum, coal-tar, and Portland cement, applied hot, and serves as a wearing surface.—B. B.

A New Paint for Stones, Plaster, and the like. F. Wendling, Munich, Germany. Eng. Pat. 10,757, July 25, 1888. 6d.

ZEOLOTIC minerals, such as Natrolite, Epidote, Chlorite, Idocrase, Apophyllite, are mixed in such proportions that the resulting mass has a composition approximating to 10—12 of silica, 2½—4 of alumina and ferric oxide, 1½—3 of lime and magnesia, 2—5 of soda and potash, 3 to 8 of water, all reckoned in equivalents, and then incorporated with sufficient suitable pigment to give them the desired colour.

Failing these, silicates of suitable composition may be prepared from a mixture of quartz, kaolin, lime and alkalis, and used in their stead. In using the patented material it should be mixed with about six times its volume of milk of lime of 22° B., and the surface to which it is to be applied should be previously moistened with water. Instead of using milk of lime, caustic lime may be added to the dry pigment, provided it be packed in air-tight vessels.—B. B.

Improvements in making a White Pigment of Lead and in Apparatus therefor. J. B. Hannay, Loch Long. Eng. Pat. 1282, January 24, 1889. 8d.

GALENA or any other lead ore is mixed with sulphur or a suitable sulphide, unless there is already sufficient sulphur in the ore to convert the whole of the lead into sulphate, and is then heated in a furnace until the lead volatilises. The fumes and combustible gases are passed into a chamber where the fumes are oxidised and the gases burnt; these are then drawn through a flue in which much of the lead sulphate is deposited, and finally forced by means of steam injectors into a wet fume condenser containing sulphuric acid, preferably a condenser similar to the one described in Eng. Pat. 16,290 of 1886.—E. E. B.

Improvements in Treating or Purifying Sulphate of Lead. J. B. Hannay, Loch Long. Eng. Pat. 1434, January 26, 1889. 4d.

SULPHATE of lead made by any process involving volatilisation is purified by treatment with dilute sulphuric acid. After washing or filtering, the sulphate of lead is obtained in a practically pure condition.—E. E. B.

An Enamel or Paint having Disinfecting Properties. L. E. Audés, Chur, Switzerland. Eng. Pat. 5792, April 4, 1889. 6d.

RESINS or copals are "picked," sifted, and powdered, and then stirred with three times their weight of water for three

hours at 10° C., allowed to stand for 48 hours, and the resulting deposit of purified resin collected in thick sacks, dried at 120° C., powdered, spread out on a well-ventilated drying floor at 18° C., and kept there for 28 days "to increase the solubility of the pulverised resin by the absorption of ozone." The product is digested for 24 hours with a solvent composed of methyl and ethyl alcohols, "formic ether," camphor, and oil of turpentine, in a boiler provided with a stirrer and heated by steam. The solution is then agitated for 48 hours with ½—2 per cent. of boric, carbolic, and salicylic acids separately or together, passed through a filter kept hot by steam, allowed to stand six weeks, and mixed with pigments inert with respect to the other ingredients.—B. B.

Improvements in Treatment of Gum Copals, Gum Resins, and other Gums for the Manufacture of Varnishes and other Solutions for Coating Surfaces, and for other uses. G. H. Smith, London. Eng. Pat. 6581, April 17, 1889. 8d.

THE object of this invention is to purify gums and render them suitable for the manufacture of varnishes. The process is of special utility for the treatment of the harder kinds of gum, as it increases their solubility, effecting this object without exposing the material to the action of heat sufficiently high to be injurious to the gums. The method consists in subjecting the gums to the action of the vapours of volatile solvents prior to their being dissolved in solvents of the same or like character to produce solutions of gums. By this process they are rendered tractable to the solvent action of the solvent liquids. The process is fully described in the patent, the specification being accompanied by two sheets of drawings illustrating the apparatus employed.—D. B.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENTS.

A New or Improved Process for Unhairing Skins and Pieces of Skins. P. Puech, Mazamet, France. Eng. Pat. 10,362, July 17, 1888. 6d.

AFTER describing the process of unhairing skins by means of a depilatory and by stoving, the patentee states that by these processes the value of the wool is much depreciated. According to this invention, the skins, after the cleansing of the wool, are dried, and then passed through a shearing machine. To produce thoroughly-washed wool, the skins are soured with warm water and soda crystals, and beaten before drying, which causes the wool to stand erect and dry straight.—B. H.

An Improvement in Tanning. J. Rivage and J. B. Matrod, Paris, France. Eng. Pat. 10,482, July 19, 1888. 4d.

ACCORDING to this invention, "alumina hydrate jelly" is applied to the tanning of hides, principally sheep, goat, or calves' skins. After tanning with vegetable substances, the skins are cleansed by hot water till free from soluble and fatty matters. "They are then agitated with an excess of alumina hydrate in solution or suspension in water until they can absorb no more."—B. H.

Improved Method of Treating Hides, Skins, or Scraps, in Liquids. C. W. Cooper, Brooklyn, U.S.A. Eng. Pats. 5674 and 5762, April 2, 1889. 8d.

IN these two patents are claimed respectively the apparatus for and the process of treating hides, skins, or scraps in

water or other liquid. An inner tank having a "slatted" bottom, and provided with perforations near the top, contains the material to be treated. This tank is enclosed on the bottom and sides by an outer tank, which is filled to a suitable height with water or other liquid. Air or other gas is then blown in at the bottom of the inner tank, and by its ascent through the liquid, agitates and exposes the material to the action of the liquid. Drawings are given, and for particulars of the plant, the specifications must be consulted.

—B. H.

XV.—AGRICULTURE, MANURES, Etc.

Experiments upon Putrefaction and the Formation of Farm-Yard Manure. J. Reiset. *Compt. Rend.* **108**, 779—785.

DETAILS are here given of the results of the experiments referred to in *Compt. Rend.* **108**, 708. 10,687 grms. of horse-dung mixed with milk of chalk, was found, at the end of 21 days, to have absorbed 209.5 grms. of oxygen, of which 192.3 grms. went to form carbonic acid. A disengagement of nitrogen took place, equal to 5.46 per 1,000 parts of oxygen consumed. 1,500 grms. of beef, cut into slices, mixed with chalk, and moistened, absorbed in 33 days 38.08 grms. of oxygen, of which 37.63 grms. went to form carbonic acid. Nitrogen was disengaged equal to 21.77 per 1,000 of oxygen consumed. In the third experiment 30 grms. of beef cut into long shreds absorbed 1.46 grms. of oxygen, with a disengagement of nitrogen equal to 59.5 per 1,000 of oxygen consumed. Complete putrefaction took place in 12 days, at the end of which time oxygen had ceased to be absorbed, and the shreds of beef were almost black.—A. R. D.

The Influence of Carbonic Oxide on Germination. G. Linossier. *Compt. Rend.* **108**, 820—821.

SOME months ago the author stated that carbonic oxide exercised a very feeble influence on the phenomena of germination, having only a retarding effect even when present in the proportion of 79 per cent. This has been disputed by C. Bernard, according to whom 17 per cent. of carbonic oxide is sufficient to arrest germination. The author thought that this discrepancy might be due either to the diminution of the oxygen tension in Bernard's experiments, or to his carbonic oxide having been imperfectly freed from carbonic acid. With a view to test this, he has made a large number of experiments with cress and lettuce seeds in varying mixtures of oxygen, nitrogen, and carbonic acid. The influence of the last-named gas did not begin to show itself till it reached 10 per cent.; and even though its effect was rather more pronounced when added to the air without a corresponding addition of oxygen, still the results throw no appreciable light on the cause of the discrepancy.—A. R. D.

History of a Field newly laid down to Permanent Grass. Sir J. B. Laws. *J. Roy. Agric. Soc. Eng.* [2] **25**, 1—24.

TWO acres of the Rothamsted estate laid down to grass in 1856 have been cropped of hay each year. The average crop was 1 ton 14½ cwt. of hay over the whole period of 23 years. The balance sheet shows an average profit of 2*l.* 8*s.* 7*d.* per acre. The amount of nitrogen put on in the form of manure was 20 lb., that of phosphoric acid 14.9 lb., and that of potash 2 lb. per acre per annum in excess of that removed in the crops. Regarding the amount of nitrogen found in the soil in 1888, as compared with that found in it in 1879, and with that calculated to be present in 1856, there appears to have been an accumulation of

52 lb. per acre per annum, of which not more than 20 lb. had been added in manure, and the author again asks the question, whence does it all come from?—J. W. L.

Annual Report for 1888 of the Consulting Chemist, Roy. Agric. Soc. Eng. Journal [2] **25**, 346—353.

THE consulting chemist again calls attention to the prevalence of adulteration in linseed cakes, and bearing in mind the frequent cases of poisonous seeds observed among these impurities, to say nothing of the fact that they are as a whole of no value, he urges strongly the use only of pure feeding materials. Sorghum has been experimented with by 52 farmers at the invitation of the Agricultural Department during the past year. Owing probably to the wet season, only in six cases did the plant grow at all, and these were apparently a failure in respect of the full maturing of the plant. Two samples were examined, more especially for sugar, and while one contained nearly half a per cent., the other was destitute of this ingredient.—J. W. L.

Harvests increased by the Use of Ferrous Sulphate in 1887—1888. P. Marguerite-Delacharlonny. *Jour. de l'Agriculture*, 1889, 61—64 and 98—103. (Compare this *Journal*, 1889, 205.)

FERROUS sulphate has been found of benefit to vines, not only as regards their growth, but also as a protection against phylloxera, &c. Vines have succumbed to the attacks of such parasites, whilst neighbouring vines treated with ferrous sulphate have thriven. Mixed with compost it is found to exert a useful influence. In meadows where lucerne and clover were attacked by *cuscuta*, the latter have been eradicated and excellent crops of the useful plants obtained by dressings of 800, 400 and 200 kilos, of ferrous sulphate per hectare respectively. Other instances of large increases of these crops and of sainfoin are given. Examples of moss being destroyed and of a meadow being visibly improved in three days by ferrous sulphate are quoted. It is stated that cattle show a preference for fodder grown with ferrous sulphate. Potatoes have yielded crops of double weight by its use. The author has succeeded in obtaining largely increased yields of oats by using ferrous sulphate in quantities double those tried by Griffiths, who used 125 kilos. per hectare. With the exception of hemp and tobacco, other cultivated plants, such as sugar-beet, peas, roots, poplars, fruit-trees, &c., have yielded well in response to applications of ferrous sulphate.

Good results must not always be expected, as they are only obtained under favourable circumstances. The quantity used must not be either too large or too small, and must be applied at the right time—best when the plants are a few centimetres high and after rain; two successive dressings are recommended. The quantities vary from 65 to 500 or even 1,000 kilos. per hectare, according to the condition of the soil and kind of plant. Small quantities are suitable for sandy soils, heavy dressings for soils rich in lime.—D. A. L.

Suppression of the Potato Disease by Ferrous Sulphate. P. Marguerite-Delacharlonny. *Jour. d'Agric. Prat.* 1889, 126—130.

EXPERIMENTS have been made by Gaillot in France which confirm the results obtained by A. B. Griffith in England with regard to its killing the *Peroouspora infestans*. The experiments were made on two acres of fertile highly-manured clay soil; 12 rows of potatoes were planted, and when they were above ground and in rainy weather six alternate rows were watered twice with a 2.5 per cent. solution of ferrous sulphate, to the extent of 10 kilos. of the sulphate per acre. At harvest these rows yielded per acre 238 kilos. of good and 5 of bad tubers, whilst 183 kilos. of good and 27 of bad tubers were obtained from the rows not so treated. Moreover, the treated potatoes remained good, whilst 10 kilos. = 6 per cent. of the others, had rotted up to December 15. The increase by the use of ferrous sulphate would thus amount to 6,500 kilos. per hectare at a

cost of 60 francs for 1,000 kilos. of the salt. Other experiments give even more favourable results. (For mode of applying the sulphate see preceding abstract.) Compost should be watered with a 1 per cent. ferrous sulphate solution to kill fungi before putting on the land.—D. A. L.

Ash of the Seed Capsules of the Cotton Plant. Annual Report of the Connecticut Exp. Stat. 1887, 81.

ANALYSES of 10 samples gave the following numbers:—

	Minimum.	Maximum.
	Per Cent.	Per Cent.
Soluble phosphoric acid.....	0.4	2.8
Reverted " "	1.0	7.63
Insoluble " "	0.69	2.40
Potash soluble in water.....	12.54	32.79

The potash is not combined with chlorine. The ash is used as a manure and is excellent for the tobacco plant.—D. A. L.

Practical Application of Hellriegel's Researches with Leguminosae (Papilionaceae). A. Salfeld. Bied. Centr. 18, 239—244.

THESE experiments are interesting as the first practical application of Hellriegel's suggestion as regards the supply of nitrogen to *papilionaceae*.

The experimental soil is high-moor (this Journal, 1889, 469) of the usual North-west German type, $\frac{1}{2}$ metres deep, with an upper layer of sphagnum peat $\frac{1}{2}$ metres thick. The northern half of the experimental land was turned over three times, burnt twice, and in 1887 carried its first crop, rye, dressed with 4,000 kilos. of lime, 160 kilos. of potash, 120 kilos. of phosphoric acid, and 60 kilos. of nitrogen as ammonium sulphate and Chili saltpetre, per hectare, and yielded 47.12 centners of grain. The southern half, previously covered with dense growth of the heathers, *Erica vulgaris* and *tetralix*, was cleared by cultivating, burning, hoeing, and treating with lime, but in the spring of 1888, even after six repeated and careful attacks, undecomposed clumps of heather and peat-moss still remained, and, therefore, the outlook for the success of leguminosae on this part was less favourable than on the northern part.

An analysis of neighbouring moor-land in 1884 showed that it contained per hectare, 2,827 kilos. of nitrogen, 179 kilos. of potash, 484 kilos. of lime, and 172 kilos. of phosphoric acid; the nitrogen of the uncultivated moor is, however, in a very insoluble form. Plots of an *are* each were covered in October 1887 with 40 kilos. per hectare of the following soils:—1. Glauconite soil from uncultivated land containing 3.73 per cent. of potash in the dry matter; very clayey. 2. Kalenberger soil, taken from the surface of a clayey soil noted for the production of horse-beans. 3. Wier soil, clayey marsh soil from Holland; on analysis a similar soil yielded per cent. of dry soil, NO \cdot 21, K₂O \cdot 80, CaO 1.70, MgO 1.31, P₂O₅ 1.54, sand and clay 80.50. In addition, each plot, and also those receiving no soil, got 4,000 kilos. of calcined lime, 160 kilos. of phosphoric acid as basic slag, and 180 kilos. of potash as kainite. The plants were drilled on April 19—24, 1888. The plants developed considerably better on the Kalenberger and Wier soil plots than on the plots receiving the Glauconite soil or none at all, and were even better on the unpromising southern part than on the northern parts of the experimental ground. The differences grew more evident the nearer the plants approached maturity. Cold and wet weather from July 29 to August 7 threw things back considerably. The peas (both field and ordinary) were the first to show the benefit derived from the fertile soils, but the other plants showed up later, and the harvest results show best with those plants which were only injured by frost, rust, and wet, but not by beating down. The results on the northern portion were as follows:—

Plant.	Soil added.	Mean Yields.	
		Grain.	Straw.
		Kilos.	Kilos.
Field peas.....	Without ..	7.975	23.175
"	Wier	10.70	43.20

Peas (<i>Pisum arvense</i>).....	Without ..	3.30	28.55
" " "	Wier	3.90	31.45

The peas on the fertile soils grew too tall and were much fallen, so that pod formation was delayed, some of the field peas rotted on the ground before reaping, and the ordinary peas could not ripen. The lentils also suffered from overgrowth, for they were so close together that they did not mature. But in spite of bad weather, the increase obtained by the use of Wier soil, for example, was with horse-beans and capucine peas 90.3 per cent. on the grain and 117 per cent. on the straw, whilst with horse-beans and lentils the increase was 208.8 per cent. on the grain and 84.9 per cent. on the straw. These results were more than could be expected under the circumstances from newly cultivated high-moor. The use of Wier soil, in fact, even if it only lasts good one season would be profitable; as, however, 4,000 kilos. appear too much in some cases, experiments are being made with smaller quantities.

It is pointed out that the beneficial action of the fertile soils cannot be mechanical, because the equally clayey Glauconite soil was inactive, nor can it be attributed to the small proportion of ash constituents contained in them. Therefore it is assumed that the application of fertile soils suitable for the growth of peas and beans, contributes to high-moorland the means of enabling leguminosae to thrive upon it with only a limited supply of nitrogen in the soil.

—D. A. L.

Economical Merits of the Soltsien and the Kellner Methods for Removing the Bitter Alkaloid from Lupins. J. Kühn. Bied. Centr. 18, 244—246.

LUPINS treated by Soltsien's method are only eaten by cattle, horses, and asses after lying a long time on the drainers, but sheep and goats eat them after three days drying. But lupins treated by Kellner's method are eaten by all animals in the fresh moist state, and as much as 3½ lb. per 1,000 lb. of live weight have been included in the daily ration without injury to milking cows.

Both methods remove the bitter principle equally well, and both diminish the dry matter to the same extent. Therefore Kellner's method is to be preferred when a steaming apparatus is at hand, and Soltsien's under other circumstances. The injurious substance *Ikroten* is generally removed by both methods, but when the *ikroten* has become insoluble on account of the age and dryness of the lupins, Soltsien's is preferable to Kellner's method, and in fact when the latter method is used it is advisable to make test-feedings for many weeks before introducing this lupin fodder generally.

Ikroten is destroyed by high temperatures, and the author recommends steaming for many hours under 2 to 2½ atmospheres pressure in order to be sure of its destruction, for it is not destroyed by the temperatures developed either in making silage or brown hay or by drying at 100°. Treated lupins constitute a good fodder, and are a good crop for light soils; but such sorts only should be selected which submit readily to the treatment for removing bitter principles, and are subsequently eaten freely by farm animals, such sorts, for instance, as:—Blue lupin (*Lupinus angustifolius*), more especially the white seeded Blue, or White East Prussian lupin (*L. angustifolius*, var. *leukospermus*), and perhaps the white-seeded Yellow lupin (*L. luteus*, var. *leukospermus*). In harvesting, moderate-sized bundles should be arranged in

a conical heap with the pods inwards, and protected with a straw cover, so as to avoid loss by shedding. The straw and shells should be strewn in the cow-shed.—D. A. L.

The Action of Salt Water on Earth and Vegetation.
A. Stood. Landw. Versuchsstat. 1889, **36**, 113.

A SOLUTION containing more than 1 grm. of sodium chloride per litre is prejudicial to vegetation. The injury is not so apparent in a wet season, but during dry weather the salt solution rises in the ground by capillary attraction and becomes concentrated near the surface by evaporation, to the detriment of the plants.—G. H. B.

Comparative Value of Equal Quantities of Nitrogen as Ammonia and as Nitrate. J. Samek. Tyroler landw. Blätter, **7**, 1889, 14—15.

SOME of the results obtained with beet-root and oats were as follows:—

Manuring per Hectare.	Yield. Kilos. per Hectare		Profit.
	Roots.	Leaves.	
			Marks.
1. 64 kilos. of soluble phosphate and 30 kilos. of ammoniacal nitrogen	30,700	3,100	120
2. 64 kilos. of soluble phosphate and 30 kilos. of nitric nitrogen.	38,500	3,200	176
3. 64 kilos. of soluble phosphate without nitrogen	29,200	2,600	156

3. "	23	2,400	10
4. "	18	1,800	..
6. "	28	3,300	-14

In both cases the nitrate proved better than the ammonia. Potash produced a quite unimportant increase.—D. A. L.

Chili Saltpetre and Superphosphate for Oats and Wheat.
Roth. Sächsische landw. Zeits. **36**, 1888, 526—531.

OATS were sown on a light soil which had received no farmyard manure since 1884, and had carried sugar-beet in 1885, barley in 1886, and flax in 1887. Wheat, following sugar-beet, was grown in a field of the same soil, which had been dressed with stable manure in 1886, and had received the leaves and tops of the sugar-beet in 1887. Various quantities of nitrogen alone, and along with various quantities of phosphoric acid, were applied, but neither the oats nor the wheat were improved by the use of phosphates, whilst the Chili saltpetre proved remunerative. Some of the results were as follows:—

Manuring per Hectare.	Yield, Centners (50 Kilos.) per Hectare.			
	Oats.		Wheat.	
	Grain.	Straw, &c.	Grain.	Straw, &c.
Unmanured	56'00	70'18	47'63	73'09

Accurate Manurial Experiments with Barley. J. Hanamann. Oesterr.-Ungar. Zeits. f. Zuckerind. u. Landw. **17**, 1888, 574—578.

THESE experiments were conducted in order to ascertain the agricultural value of a light marly soil containing 93·8 per cent. of fine earth, which consisted of 80·8 per cent. of fine sand, and 19·2 per cent. of clay, and contained 2·72 per cent. of hygroscopic, and 2·8 per cent. of combined water, 2·9 per cent. of humus, and losing 8·42 per cent. on ignition. Both the soil and the fine earth yielded 0·088 per cent. of potash to cold 10 per cent. acetic acid, whilst cold 10 per cent. hydrochloric acid extracted in 24 hours 0·194 per cent. of potash from the soil and 0·776 from the fine earth. The barley seeds were carefully selected of uniform size and weight, and allowed to germinate on moist sawdust; they were then transferred to iron cylinders with holes at the bottom, containing 4 kilos. of the air-dried soil;

five seedlings being allowed to each cylinder. The pots were so arranged as to get plenty of sun, with facilities for sheltering in bad weather. Various manures were added to different cylinders, and although the season was a bad one, nevertheless the system of experimenting allows of trustworthy deductions being made from the results obtained. The barley was benefited to the greatest extent by dressings of nitric and phosphoric acids together, to a marked degree by nitric acid alone, scarcely by phosphoric acid alone, and not at all by potash either alone or in conjunction with the other fertilisers.

On this soil, therefore, potash is not required, but both soluble phosphates and nitrates are beneficial, and should be applied in the form of ammoniacal superphosphates or superphosphate and saltpetre.—D. A. L.

Results of Comparative Experiments with Basic Slag and Superphosphate. E. Meissl. Oesterr.-Ungar. Zeits. f. Zuckerind. u. Landw. **17**, 1888, 579—609.

EXPERIMENTS with basic slag and superphosphate were conducted at 35 places in Austria. The experimental fields were in all cases as level as possible and of the same condition, that of medium fertility (preferably the second year after moderate dressings of farmyard manure). The manuring per hectare was 20 kilos. of nitrogen, as ammonium sulphate, and 60 kilos. of soluble phosphoric acid, as dissolved bones, or 150 kilos. of phosphoric acid as basic slag. The manures were mixed with soil and sown broadcast in the autumn. The experimental plots were 1,500 square metres in extent, and were separated by a non-experimental strip 75 to 100 centimetres wide. The experimental crops were in 18 places wheat, in 13 rye, in the rest meadow herbage and oats. On the whole the basic slag plots yielded rather heavier crops than the superphosphate plots, and $2\frac{1}{2}$ parts of phosphoric acid in basic slag may be definitely regarded as equivalent to, at least, 1 part of phosphoric acid in the form of superphosphate. Moreover it is certain, in most cases, that for autumn manuring superphosphate may be replaced by finely pulverised basic slag in the above proportion. It is, however, pointed out that frequently, owing to local or accidental circumstances, the action of basic slag is not so good; also for spring dressings, when readily-assimilable phosphoric acid is required, it would not be profitable to use slag instead of superphosphate. The price of a kilo. of phosphoric acid is taken at about 22 pfennigs ($2\frac{2}{3}$ d.) in basic slag, and at 64 pfennigs (little less than $7\frac{3}{4}$ d.) in superphosphate.

—D. A. L.

Manuring for Beetroots. Dingl. Polyt. J. **271**, 266—278.

Quasthoff has tried experiments with a peculiar form of potassium salt as manure, especially for sugar beets, and has obtained very good results.

The author considers that the manurial effect of the potassium in inorganic salts is only developed by combining the sulphuric acid with lime.

The potassium salt is treated by wetting it with milk of lime and then drying it or mixing it with some other dry substance, so that it can be spread over the ground. Other salts besides the sulphate can be similarly treated, and in general it is found that the addition of lime sets free the potash, and in consequence of this excellent results are obtained; in the case of beets the extra yield has amounted to 65 per cent.

The following conclusions have been drawn from experiments on the application of sulphate of iron as a manure for sugar beets:—

- (1.) The yield was increased from 5 to 30 per cent. according to circumstances.
- (2.) The application should be made during rain or when the ground is wet.
- (3.) When a solution is employed, 65 kilos. per hectare are sufficient, but not when the dry powder is spread out. According to the quality of the soil, 100 to 300 kilos., or even more, can be spread out without any bad effect.
- (4.) The increased yield affects the total solid matter as well as the sugar content of the beet.
- (5.) Along with sulphate of iron the usual chemical manures should also be used.
- (6.) The sulphate of iron, mixed with 5 or 10 times its weight of earth or sand, should be spread out after the beets have been thinned.—W. M.

The Examination of Abnormal Beetroots. Deutsche Zuckerind. 1889, 600.

CHASSEX examined beetroots which gave in the manufacture a lower yield than was expected, while no reason could be assigned for this loss of sugar. It appears that a sugar was present which gave a right-handed rotation in the polariscope, but did not undergo inversion on treatment with hydrochloric acid. This substance was precipitated by basic acetate of lead. When abnormal losses in the manufacture occur, denoting some error in the analytical methods, it is recommended to supplement the usual estimation by the polariscope by the inversion method of Herzfeld, which includes a preliminary clarification of the alcoholic extract of the roots by means of lead acetate. This will eliminate the abnormal substance before inversion.—G. H. B.

Xylose and Wood-Caoutchouc. H. J. Wheeler and B. Tollens. Ber. **22**, 1046.

THE authors have extracted from beech-wood, by means of 5 per cent. caustic soda solution and precipitation with alcohol and hydrochloric acid, wood-caoutchouc corresponding in properties to Thomson's substance.

Both substances yield on hydrolysis Koch's wood-sugar or xylose. Xylose closely resembles arabinose and turns the plane of polarisation, though much more feebly, to the right. Like arabinose, it gives no levulinic acid, but a considerable amount of furfuralamide. Its phenylosazone derivative has the formula $C_{17}H_{20}N_4O_3$, and according to Raoult's molecular weight method it has the formula $C_5H_{10}O_3$. With phloroglucinol and hydrochloric acid it gives, like arabinose, the well known cherry-red colouration.

—J. B. C.

Compounds of Raffinose with Bases. A. Beythien and B. Tollens. Ber. **22**, 1047.

LIKE cane-sugar, raffinose forms compounds with bases, some of which are less soluble in water or alcohol than raffinose itself.

Di-strontium raffinosate, $C_{18}H_{32}O_{16} \cdot 2 SrO$, is obtained by boiling for some time a strong aqueous solution of its constituents, or more quickly by adding alcohol.

Sodium raffinosate was obtained, containing from 7—8 per cent. of sodium, and less, according to the proportion of soda employed.

Eight per cent. of sodium corresponds to the composition of di-sodium raffinosate, and, in conjunction with other facts, points to the formula $C_{18}H_{32}O_{16} + 5 H_2O$ for raffinose. Barium, calcium, and lead raffinosates were also prepared. The authors will shortly publish their results in this direction, as well as the results of other researches on raffinose, and phenylosazones and their melting points.

—H. T. P.

Maize, and the Preparation of Crystallised Cane Sugar therefrom. J. H. Washburn and B. Tollens. Ber. **22**, 1047—1048.

ALTHOUGH cane-sugar has been shown to be present in maize, it has hitherto not been separated in a state of purity. The authors extracted maize-flour with alcohol and added magnesia or lime. They also employed the strontium precipitation method. In this manner the authors succeeded in obtaining crystals of pure cane-sugar from Baden maize, and also, but in larger quantity, from American sweet maize. Full information regarding this subject, as well as a quantitative examination of sweet maize in various stages of ripeness is given in another paper.—H. T. P.

A Hexyliodide from Sorbite. C. Hitzemann and B. Tollens. Ber. **22**, 1048.

ONE of the authors was unable to obtain sorbose from the juice of the service-berry, but a considerable quantity of the juice deposited crystals of sorbite. The crystals contained 9 per cent. water, corresponding to the formula $C_6H_{14}O_5 + H_2O$. By the action of hydriodic acid and phosphorus on sorbite, a small quantity of hexyl iodide, $C_6H_{13}I$, boiling at $168^\circ C.$, was obtained. This proves that sorbite belongs to the six carbon atom series.—H. T. P.

The Preparation of Gluconic Acid. A. Heffter. Ber. **22**, 1049.

MERCUROS gluconate is obtained by boiling an aqueous solution of glucose with yellow mercuric oxide as long as reduction takes place. After filtration and cooling, the salt is deposited in large white needles having a silky lustre. The reaction seems to be a quantitative one. The needles are insoluble in alcohol, difficultly soluble in cold water, easily soluble in hot water. At $100^\circ C.$, the crystals turn grey, and continued boiling with water causes the separation of mercurous oxide. Gluconic acid is obtained as a slightly yellowish syrup by decomposing the above salt with sulphuretted hydrogen.—H. T. P.

Notes on Mannose. E. Fischer and J. Hirschberger. Ber. **22**, 1155—1156.

A SHORT time ago, Reiss (this Journal 1889, 406) communicated his discovery of a new sugar—seminose—obtained by the hydrolysis of a particular variety of cellulose existing in many seeds. It forms a hydrazone bearing great similarity to the phenylhydrazone of mannose (this Journal 1889, 296 and 297) and gives a precipitate with basic acetate of lead. In a former paper the authors state that mannose gives no precipitate with this reagent. On this ground Reiss bases his conclusion that seminose is distinct from mannose. On reinvestigating the subject, the authors find that mannose does give a precipitate with basic acetate of lead. In dilute solution the precipitation takes place slowly, quickly in strong solutions. The precipitate is slightly soluble in cold water, more soluble in hot water. Mannos-oxime was also prepared. It is easily soluble in warm water, almost insoluble in alcohol. When quickly heated it melts at $184^\circ C.$ with decomposition, heated slowly, the melting point is $176-180^\circ C.$ Reiss finds 176° to be the melting point of the oxime of seminose, gas being given off. The phenylhydrazone of mannose when nearly pure melts at $188^\circ C.$, with decomposition; when quite pure and quickly heated it melts at $195-200^\circ C.$ The seminose compound melts at $185-186^\circ C.$ On these grounds the authors are of opinion that seminose is identical with mannose.—H. T. P.

A Process for Purifying Refinery Washings and other Sugar Syrups by Means of Fatty Acids, to the Exclusion of By-products. F. Harn. Chem. Centr. 1889, 330.

DRINKING the concentration of sugar juices, and after the addition of char, the organic and inorganic impurities present are so concentrated as to interfere with the crystallisation of the sugar. The author describes a process whereby these hurtful results are avoided. Experiments made on a large scale have shown that the addition of a small quantity of fatty acid (about $\frac{1}{2}$ per cent. of the total mass) serves the purpose. The fatty acid combines with the alkalis and alkaline earths, and so prevents their influence on the sugar. The raw syrup obtained by the process yields these impurities as a mud.

The author describes the following applications of his process:—

(1.) In refineries where raw sugar only is employed. (2.) In refineries where sugar is extracted from molasses, and this introduced into the raw sugar solution. (3.) In working with beet, with and without the addition of saccharate of lime.

When working the process on the large scale it is possible to obtain the sugar syrup as pure, even if raw syrup has

been added, as in working without the addition of raw syrup, and the product may be worked up for immediate consumption or as raw sugar. The after products only make their appearance if the operation is stopped, so that the last raw syrup cannot be re-introduced into the general working.—A. L. S.

A Decolourising Powder for Dark-coloured Liquids, especially for Inverted Molasses and Sugar Solutions; also for Fuel Oil, Wood Spirit, Glycerin, Crude Spirit, Acetic Ether. A. Gawalowsky. Chem. Centr. 1889, 331.

THIS powder is prepared from the residues obtained in the manufacture of ferrocyanide of potassium by treating them with 100 per cent. of hydrochloric acid for two days, then well washing and treating with 100 per cent. of a 20 per cent. solution of soda, and afterwards well washing and drying. The original material yields 50—60 per cent. of the absorption powder. Dark-coloured syrups and sugar solutions, especially those obtained in the determination of raffinose by the inversion method, are made almost as colourless as water by its use, and this without affecting their rotative power.—A. L. S.

The Diffusion Process in Java. Stammer. Dingl. Polyt. J. **271**, 266—278.

IN Vonopringo, in Java, the diffusion process has been successfully applied to the extraction of sugar from the sugar cane. Lime was added to the diffusion cylinders, and the juice passed, without filtration or defecation, to the vacuum pans, thus saving much labour and time. The water in the extracted cane chips was pressed out in the old cane mills and the chips thus dried were used as fuel for the boilers.

The following average figures show the working at Vonopringo:—

Analysis of the Cane.	29th July 1888.	12th August 1888.

PATENT.

Manufacture of a Vegetable Black for Decolourising Purposes, and Apparatus therefor. E. A. de Lisle, Paris, France. Eng. Pat. 8738, June 14, 1888. 8d.

WOOD or bark is reduced to a fine powder by suitable means, and mixed with 15 to 20 per cent. of lime. The mixture is packed in perforated iron cylinders, closed at the

ends, and heated to redness in a closed retort. It is then allowed to cool spontaneously out of contact with the air, or falls into water when red-hot, and so cooled. In either case it is washed first with dilute hydrochloric acid, to remove the lime salts, then with water, and dried. Thus obtained it has a very high decolourising power. Exhausted Peruvian bark may be so utilised without the addition of lime. Any suitable furnace may be employed. An arrangement of apparatus is illustrated in the specification for carrying in effect the operations described above.—C. C. H.

XVII.—BREWING, WINES, SPIRITS, Etc.

Purification of Alcohol by Hydrogenation. L. Naudin. Chem. Centr. 1889, 331.

Titus is a method for purifying alcohol by nascent hydrogen generated by a zinc-copper couple, sodium amalgam, or other means. It is claimed that the process described by Godefroy (this Journal, 1888, 859), depends (so far as it is of any value) on the author's principle, and the latter considers the simultaneous addition of lime and calcium chloride to be worthless and harmful.—A. L. S.

Progress in the Manufacture of Spirit. Dingl. Polyt. J. 272, 29–41.

Crude Products and Malt.—The potato-rot is detected by a slight darkening in the colour of the skin, which gradually changes to a dirty shade. On cutting through the potato, brown spots are seen. The disease is due to parasitic worms, which are most dangerous to a variety of cereals, &c. Potatoes affected with it are best used for spirit manufacture, and not for making starch. The stalk-rot is generally restricted to certain of the stalks, but may sometimes attack the bulb. It is due to a parasite which lives in the upper layers of the earth. Free access of air is the best remedy against the disease.

R. Heinzelmann discusses the employment of wheat and wheat-malt in the manufacture of spirits. As wheat contains a larger amount of substance capable of fermenting than any other cereal, the author considers it most suitable for the production of malt. The latter is more readily prepared, the yield in alcohol and extract greater, than with barley. 100 grms. of wheat-malt gave 60.08 grms. of alcohol, while 100 grms. of barley-malt gave 52.03 grms. of alcohol. Different kinds of wheat, however, behave very differently. Those richest in substances containing nitrogen are best adapted for making malt. Moreover, the summer rather than the winter crop, the white rather than the red, and the soft rather than the hard variety, may be said to be most suitable. Wheat attacked by the corn-parasite will not germinate.

Steaming and Mashing.—Too great a dispersion of the steam is not advantageous in steaming potatoes, even when they are diseased. The opposite applies in the case of maize and other cereals.

Fermentation and Yeast.—To prevent a frothy fermentation, Christek advises addition of an extract prepared from 1 kilo. of rape-seed husks with 5 kilos. of water.

For preserving liquid yeast, it is advisable to add one-eighth its volume of glycerin; pressed yeast is simply covered, in closed vessels, with glycerin. Others recommend kneading with animal charcoal, and drying in the sun. Before use, the mass is dissolved in water, and the charcoal skimmed off.

Distillation and Rectification.—L. Godefroy's process (this Journal, 1888, 859) for purifying spirits is first described.

Hoper has taken a German patent for purifying alcohol by filtering through vegetable charcoal, and the crushed product obtained by fusing together manganese oxides, alkalis, and lime. The mass is revived by igniting in presence of superheated steam.

J. Traube's method for freeing spirit from fusel oil (this Journal, 1888, 762) has been improved upon, by allowing

for more thorough separation of the layers and by an extension of the plant; so much so, in fact, that the author believes the most inferior spirit may be turned into the best quality, with excellent yield, from the crude product, and at a very small cost.

In purifying spirits by filtering through charcoal, the filters are generally made of wood, 2 metres high by 1 metre wide. The charcoal is best prepared from ash or pine wood, and used as a fine and gritty powder. This cannot be regenerated; but such a filter will last 90–100 days, with 150 litres of spirit passing through it daily.

Plant.—In connexion with a discussion as to a good apparatus for peeling the potatoes, it was elicited by C. Bennewitz, that it is advisable to leave a certain quantity of the skin in the mash, as this favours fermentation.

An apparatus for freeing spirit from fusel oil by means of petroleum is described by Ruffin.

Analysis.—Sell thinks the only reliable means at present for estimating the quantity of fusel oil in crude spirit are Roes's (this Journal, 1888, 396 and 871), and Traube's capillarimetric and stalagmometric methods (this Journal, 1888, 42 and 396). Roes's improved method. A very pure alcohol of sp. gr. .96565 at 15.5° C. is required, corresponding to 30 per cent. by volume. The specific gravity is determined in a long-necked pycnometer. To obtain an alcohol of r per cent. by volume (r less than 30) for every 100 cc. of the same $\frac{r}{30}$ (30– r) cc. of absolute alcohol at 15.5° C. should be added. When the alcohol has the required density, the apparatus for shaking is filled to the lower mark with chloroform of 15° C., the 30 per cent. alcohol contained in a 100 cc. flask added, and 1 cc. of sulphuric acid, the strength of which though otherwise immaterial, must be the same in the various experiments. The mixture is now run into the extractor, shaken 150 times, and again returned to the cooling cylinder. After a short time the increase in height of the column of chloroform is noted. Several experiments are needed with the above pure normal alcohol as a basis for the numbers. In the same manner, the increase in the volume of chloroform is determined, which results from shaking it with alcohol of .96565 sp. gr. at 15.5° C., to which a known quantity of amyl alcohol has been added.

Every 0.15 cc. increase in the volume of the chloroform layer corresponds to 0.1 per cent. by volume of amyl alcohol. The numbers differ with different kinds of chloroform, whence fresh determinations must be made when different chloroform is employed.

In examining brandy, &c., or spirit, 200 cc. of the former, or 100 cc. of the latter, are distilled with a little caustic potash, and two pieces of pumice stone. The distillate is made up to the original volume at 15.5° C., and the determination carried out as above. If b be the basis of increase in volume, experimentally found with 30 per cent. alcohol, c the increase for a certain brandy, a the amount of water or alcohol which had to be added to 100 cc. of the original brandy, to make its strength 30 per cent. by volume, the percentage by volume of fusel oil contained in it is $f = \frac{(c-b)(100-a)}{150}$. The greatest importance attaches

to bringing the alcohol up to the accurate strength, the largest permissible margin being 29.96 and 30.04 (per cent. respectively), which is often only attained by determining the specific gravity three or four times. Both the chloroform and the alcohol must have a temperature of 15° previous to mixing.

A large number of substances may influence the height of the layer of chloroform either by decreasing or increasing it. Tables are given showing to what extent this applies with 24 different bodies, both before and after distilling with caustic potash, as compared with amyl alcohol. To spirits containing a high percentage of alcohol, water should be added previous to distilling with potash. Roes's method, when carried out with all the above precautions, gives very good results. In fact, 0.01 per cent. of fusel oil may be determined without difficulty.

Several precautionary measures to be taken in Traube's capillarimetric and stalagmometric methods are described

and formulæ given for calculating the fusel oil. The influence on the results through the presence of ethereal oils, &c., is greater in Traube's than in Roesse's method. Tables are given showing, as in the latter method, how far and in what direction this influence, extends. Traube's methods, though taking less time to carry out, are on the whole not as exact as Roesse's. On the other hand, the presence of such bodies as aldehyde cannot be determined by the latter process, only the numbers corresponding to fusel oil being obtained.—A. R.

Improvements in the Manufacture of Spirit. Dingl. Polyt. J. 272, 86—93.

Detection of Aldehydes and Ketones in Spirit. (U. Gayon and G. Dupetit. *Revue Industr.* March 3, 1888.)—The test consists in the addition of a sulphurous acid solution of rosaniline (for details see this Journal, 1888, 238). According to the *Zeits. f. Spiritusind.* 11, 387, the test is not reliable. As the reagent will only keep for a short time it should be prepared in small quantities only.

Estimation of Sugar in Molasses.—Oest. ung. Brennereizeit. 12 328, after calling attention to the unreliable results of the inversion process by the use of Clerget's formula, recommends that the raffinose should be ignored and the molasses examined by the inversion process, using Creydt's formulæ—

$$1. Z. = \frac{C - 0.493 A}{0.887}$$

$$II. R = \frac{A - Z}{1.57}$$

in which A = direct polarisation, B = polarisation at 20° C. after inversion, C = difference between these two results, Z = cane sugar, R = Raffinose. (This Journal 1888, 695 and 696.)

Examination of 263 samples of Brandy from various Districts in Germany. (Zeits. f. Spiritusind 11, 334.)—The price of the brandies varied between 20 Pf. and 1.30 M. per litre, and was on the whole independent of the amount of alcohol. *Colour:* 45.7 per cent. of the samples were colourless, 9 per cent. were brown; the cause of the colour is not stated. *Acidity:* 74.3 per cent. of the samples were neutral, 16.6 per cent. faintly acid, 8.3 per cent. more so, and 0.8 per cent. strongly acid. The acidity of the samples only faintly acid was probably due to acetic acid formed by oxidation. The more acid brandies probably contained mineral acids, which was the case in both the strongly acid samples. *Odour:* 16.6 per cent. of the samples had an odour of pure alcohol only, 44.5 per cent. of fusel oil, whilst the remaining samples were aromatic from the presence of ethereal oils or cinnamic ethers.

0.50—0.60 24	9.5
0.60—0.80 11	4.2
Over 0.80 3	1.1

Windisch considers that the legal limits of the amount of fusel oil should be fixed for 100 parts of absolute alcohol, not for 100 parts of the original brandy.

The seven samples not included in the above tables yielded abnormal results when tested by Roesse's process. When distilled with caustic potash they became yellowish to brown, the distillate possessed the characteristic odour to a more marked degree than usual, and upon shaking it up with chloroform the greenish-yellow dye and all the other substances are dissolved by the chloroform, materially increasing its volume. Whether these substances possess the same injurious effects as the fusel oil from potatoes remains to be proved by physiological experiments. No sort of relation appeared to exist between the amount of fusel oil in the brandies and the price of them, or between the amount of fusel oil and of alcohol.

On the Injurious Effects of Amyl Alcohol in Brandy. (Strassmann. *Versamml. deutscher Naturforscher u. Aerzte zu Köln.*)—Dogs fed with alcohol containing 3 per cent. of amyl alcohol very soon exhibited nervous complaints and died in about half as long a time as dogs fed upon pure alcohol. With 1.5 per cent. of fusel oil the nerves were also more strongly affected, but duration of life not shortened compared with the use of pure alcohol. The author concludes that a liquid containing 0.3 per cent. of fusel oil, or only one-fifth of the smaller quantity with which he experimented, would show the same results as pure alcohol, and that the injurious effects of such a small proportion of fusel oil would be quite inappreciable compared with the much greater injurious effects of the alcohol itself.

On the Composition and Examination of Natural Brandies. (H. Roupes.)—By "natural" is meant the brandies obtained by the distillation of various fermented juices from plants. The author recommends the estimation of the alcohol, total extractive matter, acidity, and the furfural; also the qualitative examination of the different fractional distillates with rosaniline bisulphite, aniline acetate, sulphuric acid, potassium permanganate, and an ammoniacal solution of silver nitrate. The analyses given show that as a rule, compared with the natural brandies, the artificial samples are less acid and almost always contain much less furfural, often only traces.

Parasitic Bacteria in Grain. (Bernheim. *Naturforschersammlung zu Köln.*)—Pure cultivations of various cocci and bacilli were obtained from the inner part of maize and different kinds of grains, as also from leguminous seeds and tubers. In the dry ungerminated seeds only cocci are found; the rods which always appear in the cultivations must be present in the grains as spores. When germination begins the bacteria increase greatly in number, especially in the glutinous portion of the grains. The author considers that the appearance of these parasites in the gluten depends on the formation of diastase from it, and that the parasites are derived from the soil and pass up the stalks of the plant.

Diastase Ferment of Ungerminated Wheat. (C. J. Lüntner. *Wochenschr. f. Brauerei* 5, 1038.)—Wheat, contains a diastase ferment which, like malt diastase, converts starch into maltose. (Cousinier, on the contrary, maintains that the ferment in ungerminated grain forms glucose.) Although this ferment produces maltose it differs from diastase, as it cannot liquefy starch paste. It was also impossible to isolate this ferment, which can easily be done with malt diastase.

Saccharification of Starchy Substances with Hydrochloric Acid for making Spirit. (E. Bauer. Ber. Oest. Ges. z. Förderung. d. Chem. Ind. 1888, II. and III.)—A description is given of the various processes which have been proposed for replacing malt by an acid, but which have hitherto been unsuccessful. It is believed that this is due to the formation by the acid of substances which have an antiseptic acid. Details are given of the experiments, the results of which were afterwards patented by the author in conjunction with Krnis and Jahn.

Preservation of Diastase. (H. Leffmann and W. Baum. Zeits. f. Spiritus. u. Presshefe-ind. 9, 313.)—Salicylic acid and saccharin are unsuitable; boracic acid and bisulphite of soda appear to slightly diminish the activity of the diastase.

Manufacture of Dextrin. (Ljubawin. Zeits. f. Spiritus. u. Presshefe-ind. 9, 313.)—Four hundred grms. of potato starch are mixed with 200 grms. of water and 5 grms. of hydrochloric acid (sp. gr. 1.14), mixed well, and then allowed to dry, which requires about two days. The mixture is then heated over a water-bath for an hour and a half, and finally dried at 110°.—E. E. B.

The Alcoholic Fermentation of the Juice of the Sugar Cane. V. Marcano. Compt. Rend. 108, 955—957.

THE author has studied in the tropical regions the nature of the ferment and of the products which accompany the formation of alcohol from the sugar cane. The deposit from a vat of fermented cane liquor is seen under the microscope to consist of small cells much more minute than

those of beer yeast. They are round in shape and isolated from one another, not forming groups or bunches. When transferred to starch or dextrin solution, or even to another solution richer in sugar, a mycelium soon develops, the filaments of which penetrate in all directions. This yeast is most energetic at a temperature of 30°—35° C., and in a liquor containing 18 or 19 parts of sugar per 100 parts of water. When undergoing distillation the crude alcohol first gives off a gas of a disagreeable odour, and then a certain amount of methyl alcohol. The latter is followed by pure ethyl alcohol, but the last portions of this are mixed with an oily acid of an unpleasant smell, which may, however, if desired, be completely separated before rectification, as it forms with the alkalis salts insoluble in aqueous alcohol. No traces of alcohols higher than ethyl alcohol are to be found.—A. R. D.

Wines from Portugal. J. H. Vogel. Zeits. f. angew. Chem. 1889, 243—244.

IN 1888 an exhibition of Portuguese wines was held at Berlin, and the author examined some specimens shown at this exhibition. As regards the method of analysing these wines, the percentage of alcohol, which on the whole was rather high, was estimated by means of Salleron's apparatus of distillation; tannin by titration with permanganate according to Loewenthal. The acid was calculated as sulphuric acid. The determination of colour and its intensity was performed by means of Salleron's "vinocolorimeter." The extract was estimated by means of Hondrat's oenobarometer. The figures obtained were as follows:—

No.	Origin of Wine.	Designation of Wine.	Specific Gravity.	Alcohol Volume Per Cent.	Colour.	Intensity of Colour.	The Wines contained in Grms. per Litre.

Fig. 2.

B is an air heating chamber in which the air employed for dessication is heated by the steam pipes *m m*, and supplied to A through sliding openings in E. Q is the charging door. J J a moveable partition which slides down when Q is opened so as to prevent the escape of hot air from the back part of the dessicating chamber. The articles to be dried are placed on trays, R, suspended to the pitch chains running round the chain wheels mounted on the vertical spindles *e e*; the bevil wheels, *o o*, rotate these pitch wheels and the chains carry round with them the trays R. The hot air charged with the moisture extracted escapes by the outlet C, regulated by the damper *l*. The steam used in the heating pipes, *m m*, is supplied by the small boiler M placed below the whole apparatus.—C. C. H.

(B)—SANITARY CHEMISTRY.

Water Softening. G. E. Davis. Chem. Trade J. 4, 306—307.

THE author recommends that water used for boiler purposes should be so treated before entering the boiler that all formation of scale shall be prevented, and deprecates the use of substances which merely prevent the scale from adhering to the boiler. As an example of how various precipitating agents may be used in conjunction with one another, a water which contained 5.2 grs. of calcium carbonate, 24.3 grs. of calcium sulphate, 0.15 grs. of magnesium sulphate, 4.27 grs. of magnesium chloride, 17.27 grs. of magnesium nitrate per gall., was treated with a mixture of 17 grs. of caustic soda (77 per cent.), 17 grs. of sodium carbonate, 5 grs. of tribasic phosphate of sodium, with the result that of 12.9 grs. of lime only 0.78 grs., and of 6.6 grs. of magnesia only 3.78 grs. remained to enter the boiler, and this at a cost of 3½d. per 1,000 galls. The precipitate amounted to 25 tons semi-dry sludge (or 9 tons dry) from 5 million galls. of this water per week.—J. W. L.

PATENTS.

An Apparatus for Precipitating Inorganic and Organic Matter held in Solution or Suspension in Liquids, and for Purifying and Clarifying the Liquid afterwards, and for Treating the Precipitate. F. R. Lipscombe, London. Eng. Pat. 6405, April 30, 1888. 8d.

THIS specification describes several devices employed in the purification of water. (1.) The admission and regulation of the reagent used and its mixture with the water operated upon; this is accomplished by means of a reaction wheel or "Barker's Mill," worked by the incoming water, and admitting, by means of a tap in the case of liquid, or a plug in the case of solid, the measured quantity of reagent. (2.) A device for mixing the reagent with water when employed as a liquid, such apparatus being somewhat similar to that described under head (1). (3.) A form of

filtering, clarifying and settling arrangement for arresting the matter precipitated. (4.) An apparatus for treating and pressing the water from the precipitate, delivering it as a solid cake, enabling it to be recovered and used in a subsequent operation.—C. C. H.

Improvements in Means for Expelling Liquid from, and Compressing Sewage, Sludge, and other Semi-fluid or Plastic Substances. J. Price, London. Eng. Pat. 8491, June 9, 1888. 6d.

A MOUND made of wood, metal, or any suitable material strong enough to resist considerable pressure, provided with a perforated bottom, which may be packed on the under side with sponge, tow, or other soft substance, is placed upon a bed plate covered with suitable textile fabric. The interior of the mound is filled with the substance operated upon, and a plunger fitting the mound is then driven down with sufficient force to expel the water present, and pressure may be further continued to compact the residue into a solid mass.—C. C. H.

Improvements in or Connected with Apparatus for Purifying Water. A. Howatson, London. Eng. Pat. 10,098, July 11, 1888. 8d.

THE apparatus specified consists of a head tank for regulating the flow of the water; beneath this a reagent tank divided into two compartments, in which lime or other reagent may be dissolved; a receiving channel into which the water and reagent flow and mix simultaneously, and from which, by means of a pipe, it is conducted into a large settling tank below the whole, where settlement of the precipitated matter occurs. The upper part of the last-named tank is provided with a bed of filtering material through which the purified water ascends and which arrests any remaining suspended particles, and finally leaves the upper part of the settling tank by an overflow pipe.—C. C. H.

Improved Means for Clarifying, Purifying, Disinfecting, and Utilising Sewage and other Foul or Waste Waters. H. Wollheim, London. Eng. Pat. 15,321, October 24, 1888. 6d.

THE sewage is treated with milk of lime to which has been previously added, when freshly prepared, trimethylamine or an isomer; "a very soluble gas is evolved and is retained in the solution with very great tenacity." The gas so dissolved entirely destroys "every species of micro-organism occurring in sewage and other foul or waste waters." About 0.5 grm. of quicklime is used per litre of sewage, and to every volume of milk of lime equal to the treatment of 1,000 litres of sewage 0.25 grm. of trimethylamine is added.—C. C. H.

Improvements in Treating Sewage and in the Construction and Arrangement of Means therefor. H. Guthrie, Manchester. Eng. Pat. 4058, March 8, 1889. 8d.

This specification describes an improvement in the shape of the precipitating vessels used in the defecation of sewage.

B is the main sewage channel into which the hopper B¹ delivers the requisite quantity of any reagent. D is a settling tank or "débris tank" in which the larger and heavier impurities are deposited, and removed continually by the bucket wheel E. F is a strainer through which the sewage passes on its way to the conical tank or basin A, overflowing therefrom at I and conducted by channel J into suitable filters K. The sludge is deposited in the conical part of A and removed therefrom by the pipe H and pump L.—C. C. H.

(C)—DISINFECTANTS.

PATENTS.

Improved Means for Preserving Articles of Food. A. Poehl, St. Petersburg, Russia. Eng. Pat. 10,901, July 27, 1888. 6d.

The patentee finds that when salt is used for the preservation of articles of food it has more "anti-fermentive than anti-bacterial action;" certain bacteria even develop active properties in a concentrated solution of salt. On the other hand, certain ethereal oils, e.g., mustard, cinnamon, and clove, restrict considerably the activity of bacteria. He therefore proposes to use one or more parts of such an ethereal oil in conjunction with ten to twenty-five thousand parts of salt solution, and so secure "a perfect antiseptic action."—C. C. H.

A New Reagent for Disinfecting, Preservative, or Remedial Purposes. H. Wollheim, London. Eng. Pat. 16,242, November 9, 1888. 6d.

THE new reagent is "a very soluble gas," which is produced when milk of lime or other alkali acts upon trimethylamine or isomers thereof. The gas so evolved is capable of destroying in a very short space of time "the vitality of all germs and spores which can induce chemical change or disease."—C. C. H.

An Enamel or Paint having Disinfecting Properties. L. E. Andés, Chur, Switzerland. Eng. Pat. 5792, April 4, 1889. 6d.

See under XII., page 553.

XIX.—PAPER, PASTEBOARD, Etc.

New Microscopic Method of Testing Paper. F. von Hömel. Mittheil. des K. K. Tech. Gew.-Museums, 1889, 1—9.

THE microscope is generally used in the determination of the nature and amount of the different fibres composing a sample of paper, tests being made in the ordinary way for the weighting materials, size, and colouring matters.

For testing microscopically, the fibres may be conveniently grouped into—

1. Linen, hemp, and cotton.
2. Wood-cellulose, straw-cellulose, and esparto.
3. Ground wood-cellulose and jute.

According to the German official directions, the sample of paper to be tested is steeped in a solution of 1·15 grms. of iodine and 2 grms. of potassium iodide in 20 cc. of water, and then examined under the microscope. It is stated that, after this treatment, the fibres of group 1 are stained brown, those of group 2 are not coloured, whilst the strongly lignified fibres of group 3 are coloured yellow. But it is found that this method is very defective, the cellulose of group 2, for example, being invariably to some extent stained, whilst the members of group 1 are so deeply coloured that it is impossible to distinguish their structural characters. After many experiments, the following method was found most satisfactory. The paper is placed on the object glass of the microscope and treated with iodine solution, the unabsorbed iodine removed by means of filter-paper, and the paper covered with sulphuric acid of a strength found by experiment most suitable. The solution of iodine in potassium iodide should be of such a strength that a layer of 3 cc. thickness should be of a ruby-red colour and quite transparent. The various fibres, after being boiled with dilute potassium hydrate, and washed, gave, on testing by this method, the following results:—

1. Cotton, linen, hemp, bleached jute, China grass, and mulberry fibre take a red-violet or wine-red colour, the inner portions of the fibre being stained yellow. Patches or stripes of a dirty yellowish colour are seen on hemp.
2. Well bleached wood-cellulose and ordinarily bleached straw-cellulose are coloured grey-blue or pure blue without any tinge of red.
3. Unbleached or imperfectly bleached wood- and straw-cellulose absorb very little iodine, and remain colourless, at least in parts, or take a pale bluish colour.
4. Maize and esparto are coloured partly blue, partly red-violet, the real fibre being coloured red-violet.
5. Strongly lignified fibres, such as raw jute and ground wood-cellulose, are coloured yellow.

When sulphuric acid, of rather greater strength than that which is most suitable for general use, is employed in the testing, the fibres of group 1 are coloured red-violet, whilst those of groups 2, 3, and 4 are coloured entirely blue. After acting for two minutes with cold dilute nitric acid on the different fibres, the members of groups 3 and 4 absorb iodine freely, and are coloured blue with sulphuric

acid, the same treatment being without effect on the fibres of group 1; ground wood-cellulose and raw jute are stained yellow by the nitric acid, the colour being deepened by the subsequent treatment. The presence or absence of esparto in a sample of paper should be ascertained by a preliminary examination; in absence of this fibre, the foregoing method gives reliable results. Esparto is seldom or never present in German papers. The method given above only refers to white papers, the raw fibres and common papers not having undergone a bleaching process, give somewhat different results.—E. B.

Economy in Paper Making. G. E. Davis and P. Duxbury. Chem. Trade J., 1889, 274—275.

THE authors discuss the question of the economical recovery of the waste soda liquors from paper mills by the Porion system of evaporation. They also give the results of experiments made with a view of ascertaining what amount of soda could be recovered from liquors in which esparto had been boiled on the laboratory scale. For this purpose 77 grms. of esparto were boiled for five hours at 60 lb. pressure with 10 grms. of 77 per cent. caustic. The liquors which drained away yielded in evaporation and incineration 67 per cent. of the total alkali taken; the first wash yielded a further quantity of 11 per cent., and the second wash 2 per cent. The resulting pulp was dried and burned; the ash yielded 0.56 per cent. of the total alkali in the soluble form, and 5.00 per cent. insoluble. The total soda actually accounted for amounted to 85.56 per cent.—E. J. B.

PATENTS.

Improvements in Methods and Processes for Treating "Bauhinia Vahlia" and other like Fibrous Materials, and in the Application thereof to the Manufacture of Fibrous Sheets, Panels, Slabs, or Blocks suitable for various Useful and Ornamental Purposes. E. Brasier, London. Eng. Pat. 7350, May 17, 1888. 6d.

THE "Bauhinia Vahlia" or other suitable fibrous material after breaking and decorticating, is converted into pulp and is then made into webs of paper in the usual manner. Several of these webs can be joined together so as to produce slabs of any desired thickness, and they can also be treated with fire- and waterproofing solutions. In some cases wire gauze is laid between the sheets to give additional strength. The pulp may also be pressed in moulds of any desired shape.—E. J. B.

An Improvement in Discharging Excess of Bleaching Agent from Paper Pulp after Bleaching. A. Boake and G. A. Roberts, Stratford. Eng. Pat. 8840, June 16, 1888. 4d.

SODIUM metasilphite is added to the pulp, preferably immediately after the bleaching has been effected, until it is found, on testing, "that the required discharge of the excess of bleaching agent has been arrived at."—E. B.

Improvements in the Treatment or Preparation of Paper, Cardboard, Paper-pulp, Papier Maché, and other Fabrics and Metals, to Render the same Imperious to the Action of Acids, Water, Air, Mineral Oils, and other Liquids or Gases. C. D. Aria, London. Eng. Pat. 8981, June 19, 1888. 6d.

THE material is coated or impregnated with a solution of gutta-percha in bisulphide of carbon mixed with shellac dissolved in spirits of wine.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Report on New Drugs and Fine Chemicals. Merck's Bull. 2 [1].

Hydro-cinnamic acid (β-phenyl propionic acid)

THIS substance is presented in the form of acicular, reddish-white crystals, but slightly soluble in water, soluble in six parts of alcohol, and possessing a slightly acid reaction. The alcoholic solution has a pleasant acid taste and an aromatic odour. This solution has been found very valuable in cases of phthisis.

Monobrom-camphor, $\text{C}_{10}\text{H}_{15}\text{BrO}$, forms colourless prisms, permanent in the air and light and possessing an odour both of camphor and of oil of turpentine. Melting point 77° C., and boiling point 274° C. It is insoluble in water, but little soluble in glycerol, easily in alcohol, fatty and ethereal oils, ether, carbon bisulphide, and chloroform.

Stevenson (*Med. Press and Circular*, 1888, October 24) reports that since 1871 he has used monobrom-camphor as a sedative in cases of epilepsy, hysteria, &c. It is found best to use the substance in combination with belladonna.

Cannabine Tannate.—This is an amorphous yellowish or brownish powder, of very faint cannabine odour and slightly bitter, but strongly astringent taste. It is but little soluble in water, alcohol, or ether, more so in acidulated water (very dilute hydrochloric acid), and readily in acidulated alcohol. As a hypnotic, the efficacy of which as well as general value, exceed those of morphine or chloral hydrate according to Prior, Vogelsang, and Mendel, it is generally administered in quantities varying from 0.25 to 0.5 gram.

Cresol salicylates (the ortho-, meta-, and para-compounds) $\text{C}_6\text{H}_3(\text{OH})(\text{CO}_2\text{OC}_6\text{H}_4\cdot\text{CH}_3)$. All the homologous monohydroxylic phenols and many of their derivatives are more or less related in their chemical action on animal life; they are all endowed with some antiseptic, antizymotic, bactericidal, or antipyretic powers. Prominent among those practically applied for such uses in medicine and surgery are especially the initial member of the phenol series, carbolic acid, and also thymol.

Among the dihydroxylic phenols and their derivatives are some very important remedial substances, similar in their capacities to the foregoing. These are resorcinol, guaiacol, quinol, eugenol, safrol, &c.

The peculiar physiological properties of certain organic acid esters of the compound class (esters) formed from various phenols, have attracted during late years much attention. Special success as remedial agents has attended two of these compounds, viz., the *salicylates of phenol* and of *β-naphthol* ("Salol" and "Betol"). Their eligibility for internal *antisepsis* is believed to be dependent on the fact that whilst inert in the stomach they become active in the intestines, no dissociation occurring in contact with the acid gastric fluid, but decomposition taking place into a phenol and salicylic acid, so soon as they reach and are reacted upon by the alkaline intestinal fluids. Nencki, the originator of both salol and betol, has now prepared compounds analogous to these from the three cresols, viz., *ortho-, meta-, and para-cresol salicylate*. These are all crystalline, insoluble in water, with difficulty soluble in alcohol, and possessed of an agreeable odour like that of salol. The *ortho-compound* melts at 35° C., the *meta-* at 71° C., and the *para-compound* at 39° C. The *ortho-compound* produces a slight burning sensation on the tongue, whilst the *para-compound* is without taste. The dissociation of these three substances in the animal economy is not only and entirely through the action of the pancreatic fluid, but is in part delayed and accomplished through other organs when these substances have already entered the circulation, as, for example, in the muscles. Their antiseptic action is the same as that of salol, and

Nencki considers them more eligible than salol in cases where the intestinal tract is to be treated by an agent at once antiseptic and innocuous.

Mercury-β-naphthol Acetate.—This most recent mercury compound has been recommended by Bombelon (Pharm. Zeit. 98) as an excellent substitute for corrosive sublimate and iodoform for the dressing of wounds and for internal administration in syphilitic affections. It is a heavy, amorphous, white powder, insoluble in ordinary solvents. It is presented as a preparation in a 1—2 per cent. mixture with natural quartz powder (Kieselguhr), or by means of gauze, or, triturated with fresh albumen, which mixture is then shaken up with water to form an emulsion.

Narcaine Meconate ("Mecon-narcaine"), narcaine being a non-acid base and meconic acid a dibasic acid, the inference would be that a neutral narcaine meconate must contain two molecules of narcaine and one of meconic acid. When the attempt is made to form the compound thus, the solution is found to crystallise at first in yellow needles, and then in white scales gathering into globular aggregations. The yellow needles are found to be richer in meconic acid than the white scales. The product is consequently not homogeneous. But a perfectly homogeneous product is obtained by uniting 1 mol. each of meconic acid and narcaine.

The narcaine meconate thus formed is of a lemon-yellow colour, tolerably soluble in boiling water, slightly in strong alcohol, and most readily in 50 per cent. alcohol. It melts with decomposition at 126° C., the temperature at which the previously described salt also melts, and with which it appears to be identical. The reaction of true narcaine mono-meconate is acid like that of all the narcaine salts, even the normal ones.

Santonin, Santoninic acid, Sodium santoninate.—It is singular that the internal use of sodium santoninate induces a partial colour-blindness along with other visual phenomena. This has been investigated and reviewed by Dr. H. König (Nature, 1889, 408). It is a well-known fact that persons under the influence of santonin toxication see all objects as if through a yellow medium. Dr. König finds that the visual power of recognising the ulterior portion of the blue and the entire extent of the violet of the solar spectrum is entirely abolished for the time being, whilst the point of neutrality is situated at the rare length of 573, this being the exact complementary point of the suppressed violet. König infers that the visual phenomena occasioned by the ingestion of sodium santoninate do not constitute actual violet-blindness, the retina or optic nerve being affected, but that the rays of violet light are, during the santoninic toxical condition, simply absorbed by certain of the media of the eye, which have been abnormally, and of course only temporarily, affected in that direction by the drug.

Anisic Acid (Methyl ether of *p*-hydroxybenzoic acid), $C_6H_4(OCH_3)COOH$.—This monobasic acid crystallises in colourless, monoclinic prisms, melts at 180° C., and sublimes without decomposition at or about 280° C. It is very little soluble in cold water, but quite readily so in alcohol.

Antonio Curei (Deutsche mediz. Zeit. 1889, No. 12) has made numerous physiological experiments on animals with this acid. He recommends its use as follows:—

1. As an antiseptic, and in the treatment of wounds and lacerations. Thus used, he finds it equally efficacious with salicylic acid.
2. As an antipyretic, if we except articular rheumatism, it is expected to act more intensely and harmlessly than salicylic acid. Anisic acid reduces temperature without depressing the action of the heart, sustains the augmented blood-pressure, does not impair nutrition, and induces no gastric disturbance. For this internal use, indications point to sodium anisate as an eligible form for communicating the acid.

Sodium Anisate, $C_6H_4(OCH_3)CO.ONa$, is crystallisable and readily soluble in cold water. It may safely be given in larger doses, and is more easily taken than sodium salicylate.

Imperialine, $C_{35}H_{50}NO_4$. An alkaloid recently discovered by K. Fragner in *Fritillaria imperialis* (this Journal, 1889, 132).—It is a heart-poison, and is probably closely related

to the older alkaloid *Tulipine* discovered by Gerard in *Tulipa Gesneriana*.

Thallium Salts, especially the soluble ones, are highly poisonous, and must not be confounded with thalline or tetrahydroparaquinanisol discovered by Skraup in 1885, and used as the sulphate and tartrate, as antipyretic, antiseptic, and antizymotic, especially in typhus and yellow fever. It is a question whether in the solitary attempt by Pozzi and Courtade (Gaz. Med. de Paris, 1884 (13), March 29) any therapeutic value at all was discovered in it, so easy is it to pass from therapeutic to toxic effects.

Thalline, sulphate and tartrate ($C_{10}H_{13}NO$) $_2$ H_2SO_4 and $C_{10}H_{13}NO.C_4H_5O_6$.—The name of thalline was given as being suggestive of the bright green colour obtained when thalline salts are acted on by oxidising agents. With ferric chloride, e.g., this colour is produced in a solution of 1 part in 100,000 of water.

The sulphate is a yellowish-white crystalline powder, with a cumarin-like odour and an acid-saline, and also bitterish aromatic taste. It melts when heated above 100° C., and is soluble in 7 parts of cold or 0.5 of boiling water and in about 100 of alcohol, slightly so in chloroform and ether. It contains about 76.9 per cent. of the base to 24.1 of the acid.

The tartrate resembles in appearance the sulphate. It is less soluble than the sulphate, requiring 10 parts of cold water and several hundred parts of alcohol. It is nearly insoluble in chloroform and ether, and contains 52.2 per cent. of the base to 47.8 of the acid.

It is principally owing to the work of von Jaksch that its salts have gained their position in the *Materia Medica*. —W.S.

The Coca Bases. O. Hesse. Ber. 22, 665—671.

Two kinds of coca leaves are found in commerce, the one obtained from *Erythroxylon coca*, which was the original trade product, and the other, which appeared later, derived from Jamaica and St. Lucia. The latter has been used in North Germany for the preparation of coca. The author obtained from this variety the substance which is named cocaine. This is a base which may be obtained in crystals by treating with acetic acid and precipitating with ammonia. It has the formula $C_{19}H_{23}NO_3$, and combines with one molecule of hydrochloric acid. Both the base and hydrochloride decompose on heating, the former yielding methyl alcohol and the latter methyl chloride. The residue left by the decomposition of the hydrochloride is cocainelegonine, $C_{18}H_{21}NO_3$, and by a secondary reaction a small quantity of cocaine acid.

If the hydrochloride be boiled with hydrochloric acid it is split up into eugonine and cocaine acid—

This acid is identical with γ -isotropic acid of Liebermann. A second acid is also present, but the quantity is too small for analysis. It is separated from the cocaine acid by the insolubility of the lime salt. Cocaine acts physiologically like cocaine, but rather weaker. The anaesthetic action is particularly weak. The action of γ -isatropylcocaine is, according to Liebreich, of an entirely different character, being a strong poison. If the crude coca bases are fractionally precipitated and dissolved in ether and the ether evaporated a syrupy residue remains, which, after maintaining for some time at 60°, no longer dissolves completely in acids. The insoluble portion dissolves in ammonia, and is precipitated by barium chloride. This new substance may be purified by fractional precipitation. Boiled with dilute acids it yields a new acid, which has not been further investigated, and eugonine. The substance itself has the formula $C_{18}H_{19}NO_4$. The author calls the acid cocaineic acid, and the substance cocainelegonine, and methylated cocainelegonine, cocaineamine corresponding to cocaine. The brownish-yellow oil obtained by the action of hydrochloric acid upon the so-called isatropylcocaine (this Journal, 1889, 305) is probably cocainelegonine, which is formed from the cocaineamine present. This is probably

the reason that Liebermann's base has poisonous properties. The solution from which the cocaine is separated contains a mixture of bases, which, when treated with hydrochloric acid, yield ecgonine, an oily non-volatile base and hygrin, and the following acids, coccic acid, cinamic and benzoic acid. The author concludes that the amorphous bases in the genuine coca are the benzoyl compounds of an oily non-volatile base and cocaine; but that other coca varieties consist of cocaine and the cinamyl compound of the oily base, and that cocerylamine accompanies both. Both bases yield hygrin.—J. B. C.

The Coca Base. C. Liebermann. Ber. 22, 672—675.

THE paper is a criticism on the foregoing investigation of Hesse, in which the author maintains the correctness of his former researches on the alkaloids accompanying cocaine.

—J. B. C.

Hygrin. C. Liebermann. Ber. 22, 675—679.

To prepare the pure material, the crude product was dissolved in ether, separated from water and allowed to stand over solid potash. The ethereal solution was then poured off and distilled in vacuo. The oil was fractionated. One portion boiled at 128—131° under a pressure of 50 mm., and another at 215° under the same pressure. Both bases differ in so far from Hesse's analytical results, that they contain oxygen, whereas Hesse's hygrin has the formula $C_{15}H_{15}N$.

The lower boiling base boils at 193°—195° under ordinary pressure, and the analysis and vapour density corresponds with the formula $C_{15}H_{15}NO$. It forms salts and a picric acid addition product. The higher boiling substance cannot be distilled at the ordinary temperature without undergoing decomposition. From a series of analyses of the free base and various salts it appears to have the composition $C_{14}H_{12}N_2O$. Neither base is decomposed by heating with conc. hydrochloric acid to 120°.—J. B. C.

Chemically Pure Narceine. E. Merck. Chem. Zeit. 13, 525—526.

As the author has found that the melting point of various preparations of narceine melt as much as 20° above the melting point given by Hesse, he considered it doubtful whether the pure substance had yet been obtained. He obtained a sample melting at 153°, which contained 1.06 per cent. of hydrochloric acid. This amount it obstinately retains and crystallises from water containing free ammonia without losing chlorine. To prepare the pure base the author starts from chemically pure narceine hydrochloride prepared by himself. It melts at 163° with decomposition, crystallises with one molecule of hydrochloric acid, but without water. Treated with water it decomposes yielding the pure base, melting at 170°—171° with decomposition. It possesses a feebly alkaline reaction. It combines readily with acids, absorbing hydrochloric acid if present in the atmosphere, by which the melting point is at once lowered considerably. For therapeutic purposes a good quality of commercial narceine should be free from meconine, and when free from acid should not melt under 165°. Chemically pure narceine is free from acid, and melts not below 170°.

—J. B. C.

Hydrargyrum Oleicium. A. P. Brown. Amer. Pharm. Journ. 1889, 168.

MERCURY oleate is best prepared by triturating 240 grms. of fine white soap powder and 98 grms. of finely-powdered mercury bichloride with a little water. The pasty mass is boiled with water until an oily yellow liquid is formed, which is cooled and thoroughly washed with distilled water. The excess of moisture is driven off on a water-bath. The product mixes well with fats and lanolin.—G. H. B.

On "Exalgine." G. Bardet. Nouv. reméd. 1889, 5, 197.

THE author corrects a former statement made by himself and Dujardin-Beaumetz (this Journal, 1889, 412) that "exalgine" is orthomethylacetanilide. "Exalgine" is methylacetanilide, of which an ortho-compound does not exist. He states that antiseptic properties are exhibited chiefly by the hydrated aromatic compounds, like the phenols, naphthols, and "oxyphenols"; whilst the amido-compounds, like kairin, thallin, and their acetyl derivatives mostly exhibit a cooling action, which is shown most powerfully in those amido-compounds in which a hydrogen atom is substituted by a hydrocarbon radicle of the fatty series, and especially by the methyl group. The author confirms his opinion that "exalgine" is a harmless anodyne, which acts extremely well in small doses in neuralgia and diabetes.—G. H. B.

Work of the Pharmacopœia Commission of the German Society of Apothecaries. Arch. Pharm. 1889, 27, 337.

Bitter Almond Water.—To test the proportion of prussic acid, 10 grms. of the liquid are treated with 1 cc. of decinormal silver solution and a few drops of nitric acid, and filtered. The filtrate must give no immediate precipitate with silver nitrate. This test permits the presence of the small quantity of free prussic acid which may result from the decomposition of benzaldehyde during the distillation.

Chlorine Water.—A volumetric determination must show at least 0.4 per cent. of chlorine.

Distilled Water.—100 cc. treated with 1 cc. of zinc iodide starch solution and dilute acid must give no colouration in 10 minutes (nitrites). 100 cc. treated with 1 cc. of dilute sulphuric acid and 0.5 cc. potassium permanganate solution must keep the red colour a long time, and must not be quite decolourised even on boiling (organic matter).

Ereosote.—The specific gravity must not be under 1.07, whilst the present pharmacopœia allows 1.03. The alcoholic solution must give a deep blue colour with a little ferric chloride solution. Mixed with 10 volumes of alcoholic caustic potash (1:5), the ereosote must congeal after a short time to a firm crystalline mass. An admixture with phenols would retard the solidification. 1 cc. of ereosote shaken with 2 cc. of petroleum spirit and 2 cc. of baryta water must give no dirty or blue colour to the petroleum, or red colour to the aqueous layer (pyrogallie ethers from beech tar).

Oil of Carraway.—The higher boiling portion of carraway oil—the carvol—of sp. gr. 0.96 must be employed. 8 drops of the oil must dissolve to a clear liquid in a mixture of 2 cc. of alcohol and 1 cc. of water.

Oil of Clove.—The specific gravity of 1.041 is increased to 1.05 or 1.06. 5 drops of the oil shaken well with 10 cc. of lime water must separate in flocks, which tend to stick to the sides of the vessel.

Oil of Cinnamon.—1 drop well shaken with hot water and mixed with lead acetate may give a white turbidity, but no yellow precipitate, as would be produced if oil of clove were present.

Croton Oil.—Sp. gr. 0.94—0.96. Soluble in two volumes of hot absolute alcohol. An elaidin test is used to detect admixture with non-drying oils, and Hübl's test for the presence of drying oils.—G. H. B.

The relation of the Caustic Action of Carbolic Acid to the Solvent. P. Carles. Journ. Pharm. Chim. 1889, 19, 425.

A MIXTURE of 30 grms. of pure neutral glycerol with 5, 10, 20, and even 30 grms. of chemically-pure carbolic acid may be placed on the skin without causing irritation. But if the glycerol contain water, the mixture is unbearable on the skin. Further examination of this phenomenon showed that the caustic action of pure carbolic acid is greatly reduced by solution in pure glycerol or strong alcohol so long as no water is added. In cases of burns caused by

strong carbolic acid, it would therefore be better if strong alcohol were used instead of water to remove the acid from the skin.—G. H. B.

PATENTS.

An Improved Process for Extracting Moisture and Volatile Bodies from Animal, Vegetable, and Mineral Substances. O. C. Hagemann, London. Eng. Pat. 6851, May 8, 1888. 6d.

THE object of this invention is the elimination or extraction of moisture or volatile bodies from the substances specified, so as to secure their preservation in some cases, and in others in order to obtain the volatile bodies themselves. This is effected in a closed chamber by means of a suitable gas or vapour, having no action upon the substances themselves, but acting as a carrier for the said moisture and volatile bodies. The moisture or volatile bodies carried away may be removed from the gaseous medium by absorption in any suitable liquid or absorbent material.—C. C. H.

Improvements in Medicine for Human Use. H. G. Noakes, London, E. J. Tucker, Catford, and D. Clark, London. Eng. Pat. 8869, June 16, 1888. 6d.

THE patentees propose to mix any drug or drop, in suitable quantities, with chocolate, which may, if requisite, be flavoured with essential oils or essences, so as to conceal any obnoxious flavour or taste. The mixture may be divided into tablets of such a size that each shall contain a proper dose of the drug.—C. C. H.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Improved Bath with Circular Flow of Water, for Washing Photographic Pictures. W. Rooke, London. Eng. Pat. 838, January 16, 1889. 8d.

IN this invention, "the main feature is to cause a swilling action of the water upon, or against, or between the photographic prints or negatives under operation, and said photographic pictures or negatives can be placed in and removed without interfering with the inflow and outflow of water." For details of the apparatus, the specification must be consulted.—O. H.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENT.

Improvements in Explosives for Use in Fire-Arms. T. G. Hart, London. Eng. Pat. 9164, June 23, 1888. 6d.

THIS invention relates to a form of gunpowder consisting of compressed chlorate of potassium, granulated, and permeated "with a saccharine solution, or other suitable hydrocarbon liquid."—C. N. H.

XXIII.—ANALYTICAL CHEMISTRY.

An Improved Gas Blowpipe. M. Lange. Chem. Zeit. 13, 660.

THE plan advocated consists in mixing the gas and air previous to their reaching the mouth of the blowpipe. This can be effected by means of the apparatus shown in the accompanying figure, in which *a* is the outer tube conveying

the gas which enters it at the side tube *b*, *c* an inner tube concentric with *a*, and communicating with the annular space between them by means of the opening *e*, and *d* a narrow inmost tube for the blast of air, placed in such a position with regard to *c*, and having a jet so shaped as to act as an injector, and draw the gas from *a* to *c*, and thence on to the mouth. The parts marked *f* merely represent rings to support the tubes in the proper positions relative to each other.

Another method of achieving the same result is that of dispensing with the use of gas, except as a small "pilot jet" to avoid the necessity of relighting the blowpipe every time it is used, and passing the air through a vessel filled with some porous material which is repeatedly soaked with petroleum spirit from a tap-funnel. The proportions of air and inflammable vapour can be regulated by providing an alternative path for the air to the blowpipe without passing through the carburetting vessel.—B. B.

Apparatus for the Extraction of Fat. R. Fruehling. Zeits. f. angew. Chem. 1889, 242—243.

THE apparatus consists in a modification of the well-known Soxhlet apparatus, and it is claimed for the new form that that part which holds the sample to be extracted allows of a very convenient handling on weighing before and after the extraction. Fig. 1 represents the portion for the

Fig. 1.

Fig. 2.

reception of the sample. It is provided with a syphon, the longer leg of which passes through the bottom, where it is cut off aslant. The sides of the vessel A, which has the well-known form of a filter-drying tube, are continued beyond the bottom, to allow of its being placed upright on the pan of the balance. The other part of the apparatus, shown in Fig. 2, serves for the reception of the tube A, and has the customary form of a Soxhlet apparatus without the syphon-tube. Its application will be readily understood from the diagrams.—S. H.

A convenient Method of making Chromic Chloride. A. Vosmaer. *Zeits. Anal. Chem.* **28**, 324.

THE writer has made Cr_2Cl_6 by passing chlorine over ferro-chrome (containing 21 per cent. of Cr) heated in a glass combustion tube. Chromic chloride, ferric chloride, and manganous chloride (MnCl_2) are formed, and can be easily separated in the combustion tube as ferric chloride is much more, and manganous chloride much less, volatile than Cr_2Cl_6 .

If the tube be allowed to become plugged, ferrous chloride, which is difficult to volatilise, is formed.

The chromic chloride made in this way is obtained in long violet needles which are quite insoluble in water.

Ferro-tungsten, treated in the same way, did not yield tungsten hexachloride (WCl_6), but a mixture of scarlet needles of tungsten monoxytetrachloride (WOCl_4), and yellow tungsten dioxychloride (WO_2Cl_2).—H. S. P.

Boric Acid as a Plant Constituent. C. A. Crampton. *Amer. Chem. J.* **11**, 227—232.

THE author has found boric acid in a large number of samples of wine, also in the ash of a number of samples of water-melon vine fruit. In the ash of apples, Oregon sugar-beet, Louisiana sugar-cane, and cider, boric acid could not be detected. Other chemists, Baumer (this Journal, 1889, 130), Rising (Bull. Chem. Div. U.S. Dept. Agric. **19**, 38), Soltsien (Pharm. Zeit. **33**, 312), Knorr (Pharm. Zeit. **33**, 90), have all observed it as a plant constituent, the first three named chemists having detected it in wines from various parts of Europe and America, whilst the last-named found it in peach trees and fruit. As it has its origin in the soil, this detection of it in fruit grown over such a wide area would show it to be a much more widely distributed element than is generally supposed, and F. W. Clarke of the Geological Survey, United States of America, suggests that possibly soils having granitic origin would be found to contain it, whilst those of limestone formations would probably prove to be destitute of this element.—J. W. L.

A Rapid Colorimetric Method of determining Nitrates in Potable Waters. S. C. Hooker. *Amer. Chem. J.* **11**, 249—258.

THE reaction of Gräbe and Glaser between carbazol and nitric acid in sulphuric acid is the basis of this method.

Iron and chlorine must be absent; if present, the former may be removed by evaporating the water to dryness with excess of alkali and dissolving out the nitrates from the residue; the latter may be precipitated by means of sulphate of silver. The method is applied as follows:—2 cc. of the water are measured into a clean, dry test tube, 4 cc. pure sulphuric acid, sp. gr. 1.84, added, the mixture cooled, and 1 cc. of the carbazol solution added, when a green colouration is immediately formed. This is compared with the colouration produced by solutions of known quantities of nitrate treated exactly in the same way as the water under examination, and indeed at the same time, the colouration altering in intensity the longer it is kept. The solution of carbazol is made by dissolving 0.6 gm. in 100 cc. of acetic acid (99—100 per cent.), and of this solution 1 cc. is mixed rapidly with 15 cc. sulphuric acid, this latter dilute solution of carbazol being made up fresh on the day it is required, while the acetic acid solution remains good almost indefinitely.

The amount of nitrogen as nitric acid which may be operated upon in any determination may vary between 0.03 and 0.40 parts in 100,000, so that quantities either greater or less than these may be successfully determined by either diluting or concentrating the water. The author recommends that the potassium nitrate solution shall contain 0.0004 gm. of nitrogen in 1 cc., and that from this a second solution of $\frac{1}{10}$ the strength be prepared as required.

—J. W. L.

The Detection of Nitrous Acid in Drinking Water. B. Proskauer. *Pharm. Ch. N. F.* 1889, 260.

WITH reference to a recent communication by F. Musset (this Journal, 1889, 420) on the blue colouration produced by bacteria during the testing of a drinking water by zinc iodide, starch, and acetic acid, the author remarks that J. Rahemann has made the same observation. The author considers that a distillation of the nitrous acid may give rise to errors, and recommends testing with *m*-phenylenediamine, or to remove the bacteria by filtration through dense filter-paper before treating with the iodised starch. He also refers to the importance of testing the water samples for nitrates, nitrites, and ammonia as soon as they are received in the laboratory, as these nitrogen compounds are subject to change on keeping.—G. H. B.

On the Detection of Phosphoric Acid of Mineral Origin. J. Stoklasa. *Chem. Zeit. Rep.* **13**, 141.

LORENZ proposed (this Journal, 1889, 307) to take advantage of the fact that phosphates of mineral origin are richer in fluorine than those of animal origin, in testing for mineral phosphates in artificial manures. His test depends on the formation of silicon tetra-fluoride and the decomposition of this with water, whereby silica is deposited.

The author has determined the fluorine, by Fresenius's method, in a sample of spent animal charcoal, and found it to be 0.26 per cent., while that in bone meal was 0.11—0.16 per cent. that in steamed bones was 0.31 per cent., and that in bone ash was 0.57 per cent. Fresh bones, finely ground, did not give Lorenz's reaction, and bone ash only gave it feebly. One per cent. of calcium fluoride added to the ground bones gave a very distinct reaction. Bones which had been buried for 20 years gave much the same reaction as fresh bones, but all fossil bones contain relatively as much fluorine and ferric oxide as mineral phosphates do; in time bones acquire fluorine and iron compounds from clay and humus soils.

Superphosphate made from fresh bones, from steamed bone meal, and from spent animal charcoal did not give Lorenz's reaction, while that made from bone ash gave it feebly, but that made from alluvial bones gave a distinct reaction.

The author concludes that Lorenz's reaction is uncertain, and points out that the origin of the phosphate does not much affect the value of the superphosphate.—A. G. B.

On Capillary Analysis and its various Applications.

F. Goppelsröder. *Mittheil. d. k. k. technolog. Gewerbe-Museums in Wien*, 1888, 86; 1889, **3**, 14.

A VERY extensive treatise on experiments made since 1861 with the object of rendering capillary phenomena useful in analytical practice. In inorganic analysis very small quantities of substances in solution may be detected by the method. For example, natural waters were tested by hanging long strips of Swedish paper, cotton, linen, woollen and silk cloth over and dipping into 40 cc. of the water for 24 hours. When the water contained only a trace of iron, this was shown by a yellowish zone high up on the strip of paper or cloth, on which iron could be identified by touching with dilute acid and potassium ferrocyanide. Waters containing organic impurity give similar zones, which can be distinguished from iron by their passivity to reagents. In organic chemistry and in the examination of colouring matters, the capillary method is especially applicable. Solutions of the alkaloids give rather high-lying zones,

which may be tested by touching with the suitable reagents. A solution of a pure colouring matter will give one or more zones of the same colour, but the presence of even traces of other colours becomes evident by the formation of separate zones. The composite nature of a given dye may thus be detected where other methods of analysis would fail. The coloured zones can be examined with the spectroscope as they stand or in solution made by extracting the colour from any particular part of the strip of paper, cloth, or parchment. Such solution can also be subjected to further capillary analysis. The delicacy of the method is very great. Strips of material dipping a few millimetres into 40 cc. of a solution containing only 0.0000019 gm. of magenta acquired zones more or less coloured in each case. The height of the zones above the surface of the solution varied between 3.5 cm. in the woollen strip and 5.7 cm. in the silk strip, the height on paper being 4.5 cm. The author shows the applicability of the method for the examination of coloured waste waters, food-stuffs, and the various matters concerned in sanitary and judicial chemistry. It is also adapted to the examination of the colouring matters of plants. In concluding his work on capillary analysis, which embraces thousands of experiments, the author treats of the diffusion of colouring matters in plants. The plants were kept with their roots in aqueous solutions of the colouring matters for several days or weeks, and their several parts were then examined. Certain colours were able to penetrate as far as the blossom, but others, such as methylene blue, did not extend far from the root.—G. H. B.

On the Analysis of Gases. C. Winkler. Zeits. Anal. Chem. **28**, 269—289.

This paper deals with the estimation—(1) of carbonic oxide, (2) of heavy hydrocarbons, and (3) of methane.

(1.) W. Hempel has described (Ber. **20**, 2344; this Journal, 1887, 747) the phenomenon observed by K. Markel, viz., that when a volume of gas is brought in contact with a solution of cuprous chloride, for the purpose of absorbing carbonic oxide, the volume of the gas is sometimes increased instead of decreased. Hempel, at first, suggested as an explanation, that cuprous chloride absorbed ethylene and afterwards liberated it when brought in contact with a fresh volume of gas. H. Drehschmidt (Ber. **20**, 2752; this Journal, 1888, 133), however, showed by experiment and by reference to the published work of A. Tamm (von Jüptner, Prakt. Handb. f. Eisenhütten-Chemiker, 243), that this increase of volume might take place in the entire absence of ethylene and other heavy hydrocarbons, and maintained that the explanation was to be found merely in the loose state of combination in which the CO is held by Cu_2Cl_2 . He also pointed out that the phenomenon was more noticeable when a hydrochloric acid solution of Cu_2Cl_2 was used than with an ammoniacal solution, and further, than an ammoniacal solution, after having developed the property of giving up a part of the CO previously absorbed, gradually lost this power, owing to the oxidation of the CO to CO_2 , and the consequent deposition of metallic copper. W. Hempel (Ber. **21**, 898; this Journal, 1888, 403) did not uphold his former statement, but ascribed the phenomenon to the mere physical absorption of the other gases brought in contact with the Cu_2Cl_2 , and their subsequent rendition in presence of a fresh volume of gas. But H. Drehschmidt (Ber. **21**, 2158) clearly showed by further experiment the accuracy of his position; and proved—(1) that an ammoniacal solution of Cu_2Cl_2 is better than a hydrochloric acid one for absorbing CO; (2) that two absorption vessels should be used, the first to absorb the chief part of the CO, and the second to absorb the remainder; after a time the second vessel to be used as a first absorber, and a fresh one used as second; (3) that both acid and ammoniacal solutions of Cu_2Cl_2 , when charged to a certain point with CO, will give up a portion of the CO to fresh gas brought in contact with them. The more CO a solution has absorbed, the more readily it will give it up. By keeping an ammoniacal solution for some time, it loses this property, owing to the formation of carbon dioxide with deposition of metallic copper. (4) That the error due to the physical absorption of

other gases besides CO is very small in comparison with that due to rendition of CO, but that, as stated by Hempel, such absorption does take place is no doubt true.

The author, without quoting figures, states that his experiments fully bear out Drehschmidt's conclusions. He finds that when a solution of Cu_2Cl_2 , either in HCl or in NH_4OH , has been often used to absorb CO, it will give up, if shaken with hydrogen, a volume of CO amounting to as much as 2.3 per cent. of the volume of H used. When a strongly ammoniacal solution is used, it is necessary to wash the gases with dilute H_2SO_4 before measuring the contraction, and the author suggests that perhaps this operation might be avoided by using a weakly ammoniacal solution of Cu_2Cl_2 dissolved in ammonium or sodium chloride. The fact that CO is oxidised to CO_2 in an ammoniacal solution of Cu_2Cl_2 indicates that if a substance could be found to prevent the precipitation of cuprous hydrate from an acid solution of Cu_2Cl_2 by KOH (as sugar, glycerol, and other organic substances, prevent precipitation in solutions of cupric salts), then we should have an absorption medium for CO, which would effect the complete oxidation of the CO with formation of a carbonate, and, in the presence of enough Cu_2Cl_2 , last until the KOH was saturated. Unfortunately such a substance is not yet known.

The author is unable to confirm Leybold's statement (Chem. Zeit. **12**, 1277) that Cu_2Cl_2 which has become somewhat oxidised by the air, gives up this oxygen when it absorbs CO. He thinks Leybold may have been led into error from using phosphorus as an absorbent for the O in coal gas, as the author found no oxygen when he used alkaline pyrogallol.

The writer then details experiments upon the behaviour of carbon monoxy-cuprous chloride with solutions of palladium chloride. This salt has no reaction with Cu_2Cl_2 , but if the Cu_2Cl_2 solution contain CO, then under certain conditions a black precipitate of metallic palladium is formed, according to the equation $\text{PdCl}_2 + \text{CO} + \text{H}_2\text{O} = \text{CO}_2 + 2\text{HCl} + \text{Pd}$.

The formation of this precipitate affords a very delicate test for CO. As a result of the author's experiments, he proceeds as follows:—The Cu_2Cl_2 is dissolved in a saturated solution of NaCl, and the gas to be tested is passed through some of this liquid. After the absorption the solution is diluted with four or five times its volume of water, and a drop or two of sodium palladious chloride is then added; if CO be present, a black spot is observed to form where the drop of yellow-coloured palladium salt mixes with the solution. In this way 0.01 cc. = 0.0000125 gm. of CO may be detected. The author has also devised a volumetric method of estimating carbon monoxide, founded upon the fact that when carbon monoxide is passed through a mixture of cuprous chloride, and sodium palladious chloride, both dissolved in saturated NaCl solution, the palladium salt is reduced and the CO oxidised and given off as CO_2 . By absorbing the CO_2 by KOH a contraction is observed equal to the CO present. The method was accurate in the author's hands, but occupies much time, and he does not recommend it.

(2.) The author's experiments on the estimation of the heavy hydrocarbons and of benzene, lead to the following conclusions:—(a.) Fuming sulphuric acid rapidly and completely absorbs ethylene and benzene. It cannot be used to determine their respective amounts when they occur together. (b.) Fuming nitric acid absorbs ethylene nearly, but not quite, as completely as $\text{H}_2\text{S}_2\text{O}_7$. Its action on benzene is somewhat less complete. Moreover, it has an oxidising action on CO, which is so often present in gas mixtures. (c.) Bromine-water acts rapidly, but incompletely, as an absorbent for ethylene; its action on benzene is less rapid and less perfect. (d.) It follows that fuming sulphuric acid is the best absorbent for ethylene and benzene; it cannot, however, be used, in mixtures of these gases, to estimate their respective amounts. As yet, no means of doing this is known. These results are in accordance with those of H. Drehschmidt (Jul. Post, Chem. techn. Analyse, 2 Ed. vol. 1, p. 108), and of F. P. Treadwell and H. N. Stokes (Ber. **21**, 3131; this Journal, 1889, 64).

(3.) The estimation of methane by combustion with air over heated cupric oxide, absorption of the CO_2 thereby

formed, by a standard solution of baryta-water, and determination of the excess of barium by oxalic acid, is a method well suited to the analysis of large volumes of a gas containing but a small quantity of methane, as, for instance, in testing the air of coal mines, but when the gas is rich in methane, as is the case with illuminating and heating gases, the method is tiresome and too long. The writer recommends the following process for gases rich in methane:—Into the neck of the inverted tubulated Hempel pipette (shown in the figure) an india-rubber cork is fitted. Through

two holes in the cork are passed two varnished brass rods which reach to within 2—2.5 cm. of the upper end of the pipette. These rods are fitted with screws for connecting them with the poles of a battery of two Grove's cells; the ends inside the pipette are united by a spiral of platinum wire about 0.35 mm. thick, the spiral having about six turns formed by wrapping the wire round a needle 1.3 mm. in diameter. The pipette is completely filled with water before the gas to be burned is introduced. Supposing the gas to be tested is a sample of illuminating gas, the CO_2 is first absorbed by KOH , the heavy hydrocarbons by fuming sulphuric acid, the oxygen by alkaline pyrogallol, the CO by an ammoniacal solution of Cu_2Cl_2 . The gas that remains (or a portion of it), consisting of H , CH_4 , and N_2 is then mixed with enough air to burn the H , and the mixture is led over gently-heated platinised asbestos; one-third of the ensuing contraction represents the amount of oxygen that has been consumed. The oxygen still present, due to air, can then be reckoned, and the amount of N due to air is known. The difference, consisting of CH_4 and the N of the gas, is mixed with air so as to contain one vol. of O to two vols. of the residual gas. The battery is then connected with the above-described apparatus, and the mixed air and gas are allowed to slowly enter the pipette until the water with which it was filled leaves the platinum spiral exposed. The spiral then begins to glow, and the combustion of the CH_4 takes place quietly and without explosion. The whole of the gas is allowed to flow slowly into the pipette, and a minute suffices to complete the combustion. But if the gas be introduced too quickly, or if the pipette is first filled with gas, and then the battery connected, an explosion may occur which might blow the cork out. The CO_2 that is formed by the combustion is absorbed by KOH and one-third of the contraction gives the volume of CH_4 . The method is a modification of that used by Coquillon (Compt. Rend. 1877, 84, 458), who employed a palladium spiral and led the gas backwards and forwards over it, combined with a method

by A. Schornidorff, who used an inverted pear-shaped or cylindrical glass vessel filled with water as the combustion chamber. He also allowed the gas to remain quietly in contact with the glowing spiral instead of leading it backwards and forwards over it. The advantage of this is that the wire is not subjected to frequent coolings and the combustion takes place more quickly.—H. S. P.

Volumetric Estimation of Thallium and of Mercury.
W. Feit. Zeits. Anal. Chem. 28, 314—322.

The usual way of estimating thallium is by precipitation as thallous iodide. The precipitate takes some time to settle, and, after settling, is collected and dried at 110° — 120° on a weighed filter. The results, although concordant, are too low, owing to the partial solubility of the precipitate of TlI . The author has devised a volumetric method depending upon the liberation of iodine when potassium iodide is added to an acid solution of a thallous salt:—

After the greenish-grey precipitate of TlI and I has formed, the liquid is rendered alkaline with sodium bicarbonate, and sufficient decinormal arsenious acid added. The iodine is thus converted into hydriodic acid, and the precipitate (now consisting of pure TlI), turns to a bright yellow colour. This is separated by filtration, and the excess of As_2O_3 is estimated in an aliquot part of the filtrate by titration with $\frac{1}{20}$ normal solution of iodine, using starch as indicator. It is best to operate on the thallous sulphate. Thallous salts may be converted into the sulphate by heating with sulphuric acid, and the halogen compounds and thallous salts may be converted into the sulphate by adding the requisite quantity of sulphuric acid, and boiling with bromine water. A sample of thallous sulphate containing, theoretically, 81.12 per cent. of Tl (but of which the actual composition cannot be positively determined), gave, by the gravimetric method, 79.52 per cent. of Tl , and by the volumetric 80.18 per cent.

The author's volumetric method of determining mercury depends upon the reactions represented by the equations—

In carrying out the method, the mercury compounds are all brought into solution as mercuric compounds. To the solution more than enough caustic soda needed to precipitate all the HgO is added, then an excess of decinormal As_2O_3 solution is poured in, and the liquid boiled and allowed to stand for 5—10 minutes. It is then cooled, and the precipitate of mercury separated by filtration. An aliquot part of the filtrate is taken, the alkali neutralised with hydrochloric acid, and then, after addition of excess of sodium bicarbonate, the excess of As_2O_3 is determined by titration with $\frac{1}{20}$ normal iodine solution. A sample of pure mercuric chloride, containing 73.80 per cent. of Hg , gave, in five determinations, results varying from 73.73 per cent. to 74.49 per cent. of Hg .

When operating upon the sulphides (which must be dissolved in nitrohydrochloric acid) or upon substances which must be brought into solution with nitric acid, and which contain chlorine compounds, the free chlorine that is formed would combine with the caustic soda afterwards added, producing oxychlorine acid salts, which have an oxidising action on As_2O_3 . The chlorine cannot be expelled by evaporation, as mercury would be thereby lost. To obviate this, after bringing the compound into solution, an excess of sodium bicarbonate is added, and then potassium iodide until the precipitate of HgI_2 redissolves. The separated iodine, which colours the solution yellow, is then converted into hydriodic acid by a few drops of sodium sulphite or arsenious acid. Any slight excess of either of these is next removed by a dilute solution of iodine, using starch solution as indicator, and then the volumetric process as above described may be proceeded with.—H. S. P.

Estimation of Silicon and Iron in Cryolite. R. Fresenius and E. Hintz. *Zeits. Anal. Chem.* **28**, 324—327.

THE authors find that when cryolite is decomposed by heating with sulphuric acid, that nearly all the silica remains as sand, and that only a very small proportion is evolved as tetrafluoride. To obtain the total amount of silica, they effect the decomposition in a U-shaped leaden tube, connected, on the one hand, with a wash-bottle containing sulphuric acid, and on the other, with two smaller U-shaped leaden tubes, which are moistened inside with ammonia. All the connexions are made with india-rubber corks and small lead tubing. The last of the smaller U-tubes is connected with a glass U-tube, trapped with water, which in turn is connected with an aspirator. The decomposition tube is first moistened with sulphuric acid and heated to 260°, which forms a protective coating of lead sulphate inside it. About 5 grms. of cryolite are treated in this tube with 15 cc. of conc. sulphuric acid and heated on a sand-bath to 200° for two hours, while a slow current of air is continuously drawn through the apparatus. The contents of the decomposition tube are then washed into a platinum dish and boiled with water and a drop or two of hydrochloric acid to remove alumina, &c. The residue contains the whole of the silica except a minute quantity that has passed over as silicon fluoride and which is retained in the tubes containing ammonia. This residue is fused with sodium carbonate. For fear a small quantity of fluoride has been left, the fused mass is first triturated with water and filtered from the insoluble residue; the aqueous solution is then only partially neutralised with hydrochloric acid so that after evaporation the greater part, but not all, of the silica is precipitated (1). This is filtered off and to the filtrate is added an ammoniacal solution of zinc carbonate, and it is then evaporated until the ammonia is expelled. By dissolving the precipitate thus obtained in nitric acid, and evaporating to dryness, &c. in the usual way, the silica from this portion is obtained (2). The portion of the melt that was insoluble in water is treated with hydrochloric acid and the silica obtained in the usual way (3). The silica contained in the smaller leaden U-tubes is next determined. It is necessary to filter the ammoniacal liquor from the lead sulphate that has formed in the tubes. The silica is obtained from the clear liquid by first adding so much sodium carbonate as to render it alkaline, after boiling off the ammonia, and then precipitating with zinc carbonate, &c. (4). To guard against any possible loss of silica, the precipitate of lead sulphate, from the ammonia tubes, is burnt off, a few drops of nitric acid added, and the lead sulphate dissolved out with ammonium acetate. Any residue is weighed as silica (5). The sum of the weights of these five portions of silica gives the total weight of the silica in the sample. Three samples of cryolite were found to contain, respectively, 0.80 per cent., 1.23 per cent., and 1.39 per cent. of Si.

The iron in cryolite is determined by decomposing the mineral with sulphuric acid and filtering. The residue is fused with sodium carbonate and the silica precipitated by hydrochloric acid. The solution obtained after filtering from the silica is added to the previously obtained solution in sulphuric acid, and boiled with chlorine water to oxidise the iron. On pouring the solution into hot concentrated caustic potash, a small precipitate of ferric hydrate is obtained which may be estimated by conversion into sulphide and finally oxide, or (after reduction), by titrating with potassium permanganate.

The three samples above mentioned were found to contain, respectively, 0.11 per cent., 0.85 per cent., and 0.88 per cent. of Fe.—H. S. P.

Notes on the Estimation of Sulphur in Burnt Ore, &c.
G. Lunge. *Zeits. f. angew. Chem.* 1889, 239—240.

THE author once more investigated all the methods published for the quantitative determination of sulphur in burnt ore, and found that Watson's modification of Pelouze's process (this Journal, 1888, 305) was not only the simplest and cheapest, but also the quickest and most accurate test ever devised.—S. H.

Sodium Hypophosphite as a Reducing Agent. C. Reinhardt. *Stahl und Eisen*, 1889, **9**, 404.

THE author considers this substance to be a better reducing agent in ironworks laboratories than sulphurous acid or sulphites. It reduces ferric chloride even in concentrated solution and in presence of large excess of acid on heating, and does not decompose with sulphuretted hydrogen, so that it is not necessary to get rid of excess of reducing agent. On account of its hygroscopic nature, sodium hypophosphite must be kept in glass stoppered bottles. The author used a solution containing 200 grms. of salt in 400 cc. of water.—G. H. B.

Estimation of Chromium in Iron and Steel. C. Reinhardt. *Stahl und Eisen*, 1889, **9**, 404.

THE process depends on the fact that chromic oxide is completely precipitated on heating with zinc oxide, whilst ferrous and manganous chlorides remain in solution. The reduction of the ferric chloride is effected by heating with sodium hypophosphite. Excess of zinc oxide is then added and heated for some time before filtering. The precipitate is redissolved in dilute hydrochloric acid, heated with a little sodium hypophosphite and again precipitated with a slight excess of zinc oxide. The precipitate is then twice redissolved in acid and reprecipitated with ammonia to remove zinc.—G. H. B.

The Estimation of Copper in Iron and Steel. C. Reinhardt. *Stahl und Eisen*, 1889, **9**, 405.

THE solution of the metal in hydrochloric acid is heated with sodium hypophosphite to effect the complete reduction of the iron, and the copper is then precipitated by a current of sulphuretted hydrogen. The sulphide is filtered, ignited, and weighed as cupric oxide. If the latter is required to be free from small traces of iron, the sulphide is redissolved and the above process repeated.—G. H. B.

An Error accompanying the Estimation of Nitrates in Soils, &c. M. Gimti. *Le Stazioni Speriment. Agrar. Italiane*, **15**, 1888, 5—15.

THE author observed, during the extraction of certain soils with water for the estimation of nitrates, that the percentage of nitrates became smaller the longer the soil remained in contact with the water. This is found to be due to the activity of denitrifying organisms, and can be prevented by sterilising the soil or other material undergoing extraction. To effect this the author adds 5 cc. of chloroform to 500 grms. of soil, requiring about 1 litre of water for extraction.

Delicate Reaction for the Detection of Rosin. Mittheil. des K. K. Tech. Gew.-Museums, 1888, 77—78.

IN a previous paper (Mittheil. 1888, 14; see also following abstract), on Storch's test for rosin, reference was made to Holde's test for the same, in which sulphuric acid of sp. gr. 1.53 is employed. Holde now makes a communication to the effect that his method is essentially different from that of Storch, inasmuch as, besides using weaker acid, he dispenses with the use of acetic anhydride.—E. B.

Detection of Rosin-oil and Rosin. T. Morawski. Mittheil. des K. K. Tech. Gew.-Museums, 1888, 77—81.

IN testing by Storch's method (this Journal, 1888, 136, 526, and 871) for the presence of rosin in the cake of fatty acids separated from soap, the author finds it preferable to use sulphuric acid of sp. gr. 1.53 instead of stronger acid. Again, when heat is applied to dissolve an oil in acetic anhydride, and sulphuric acid of sp. gr. 1.53 added to the cooled solution, the colouration is frequently, even in

absence of rosin oil, so intense that the latter can only be detected with difficulty; but, by adding sulphuric acid of the same strength to a solution made in the cold, the colouration, as a rule, is paler and the rosin reaction therefore not hidden. The majority of oils give paler and more greenish colourations when they have been dissolved in the cold, those obtained after heating with acetic anhydride being generally dark brown or reddish-brown.

The quantity of rosin in hard soap may often be roughly ascertained by this test, but it is preferable to estimate gravimetrically the amount of rosin contained in soft soaps, as these frequently contain fatty acids which give dark colourations.—E. B.

The Colour-Reaction of Oil of Cloves with Aniline Sulphate. E. Nickel. Chem. Zeit. **13**, 592.

THE author has previously shown that eugenol gives a yellow colour with aniline sulphate (this Journal, 1889, 421); this reaction is also given by oil of cloves, which contains eugenol.

If filter-paper (free from lignin) be impregnated with oil of cloves and then with aniline sulphate a reaction similar to the so-called "lignin-reaction" of wood is obtained.

Sodium nitroprusside is a reagent for aldehydes, for the group CO, as has already been pointed out by Weyl and Legal.—A. G. B.

On the Composition and Nature of Spent Animal Charcoal. G. Stoklasa. Chem. Zeit. Rep. **13**, 147.

THE author found in a sample of spent animal charcoal an excess of 1.75 per cent. of CaO over the quantity required to form the normal salts present, and infers from this that the compound CaHPO_4 must be present, as well as ordinary tricalcium phosphate. He objects to reporting the phosphoric acid found by the molybdic method as tricalcium phosphate as the waste material contains considerable quantities of iron and alumina, whilst the method involving titration with uranium solution is inexact in presence of these impurities. He recommends the precipitation by molybdic solution with the modification of P. Wagner, and the precipitate should be washed with water which dissolves the ammonium silicon molybdate, the phosphoric acid compound remaining insoluble. This method of operating removes any necessity for evaporating to dryness to separate silica, a fact recently established by Isbert. Meissl considers that the presence of 0.6 to 2 per cent. of ferric or aluminium phosphate in superphosphate made from animal charcoal is an evidence of admixture with mineral phosphate, but the author thinks this conclusion untenable, as spent animal charcoal may normally contain these impurities.

—G. H. B.

Analysis of Turkey-Red Oil. F. Breinl. Mittheil. des K. K. Tech. Gew.-Museums, 1888, 81—85.

THE author has previously used the term "total fat" to designate the mixture of neutral fat, fatty acid, hydroxyoleic acid, and fatty-sulphuric acid contained in Turkey-red oil, this being the generally accepted definition of the term. On this understanding of the meaning of the term the author compared the analytical results obtained by the various methods in use for the testing of Turkey-red oil, and criticised the methods (see this Journal, 1888, 872). Benedikt has, however, recently proposed another definition for the term, which he suggests should denote the mixture of all the insoluble fatty matters and the oxyleic acids, formed by the decomposition of the fatty sulphuric acids. Under this definition, the percentages of "total fat," found by the methods of Stein and Brühl, become higher and still more incorrect, whilst that obtained by Benedikt's method is reduced to within half per cent. of accuracy, a closer degree of accuracy being difficult to obtain on account of the danger of injuring the fatty matters, on completely removing the sulphuric acid.

Another method of analysing Turkey-red oil, stated to be due to Finsler, is largely employed in practice. A flask of about 200 cc. capacity provided with a long neck, which is graduated to $\frac{1}{2}$ or $\frac{1}{10}$ cc., is used for the test. The lowest graduation represents a capacity of 150 cc., the uppermost 200 cc. Exactly 30 grms. of the oil to be tested are weighed out, washed into the flask, and the volume made up to 100 cc. with water, then 25 cc. of sulphuric acid of 62 B. are added, and the mixture heated to the boil. Hot water is next added until the separated layer of fat rises into the neck of the flask, its volume being read after the lapse of half an hour. The oil, as a rule, rises better if a little of a hot concentrated solution of common salt is added. After the sulphuric acid has been added it is necessary to maintain the mixture at the boil and to shake frequently until the separated oily layer is quite clear and transparent. Concordant results are obtained by closely adhering to the above method. The calculation is made from the formula $G = 3V$, where G denotes the percentage of total fat, V the volume of separated oily matters. The old formula $G = \frac{1}{3}V$, obtained with Stein's method, is incorrect. The method is suitable for rapid analyses, where a high degree of accuracy is not required.—E. B.

The Analysis of Commercial Dextrin. C. Hanofsky. Mittheil. des K. K. Tech. Gew.-Museums, 1889, 56—59.

IN the analysis of the dextrin of commerce there have to be determined: 1. Dextrin; 2. Starch; 3. Sugar; 4. Ash; and 5. Moisture.

The estimation of the portion soluble in cold water is made by mixing 25 grms. of the sample with water in a 500 cc. flask, filling to the mark and allowing to stand. The slightly turbid solution is then filtered and used for the determination of (a) maltose, (b) dextrin, and (c) acidity.

(a.) The maltose is determined by means of Fehling's solution diluted with four times its volume of water to avoid the necessity of making corrections for the density of the maltose solution. A preliminary test is made to find what amount of the solution will reduce 10 cc. of the Fehling's solution, then 1 or 2 cc. less are taken and diluted with water to make 57—58 cc. Soxhlet found that four minutes' boiling was required for maltose to fully reduce Fehling's solution. One part of copper is reduced by 0.808 part of maltose; suppose, therefore, that 100 grms. of substance contain m grms. of maltose.

(b.) 50 cc. of the filtered solution (or 100 cc. if the amount of insoluble matter be large) are diluted to 200 cc., and boiled for two hours with 15 cc. of hydrochloric acid of 1.125 sp. gr., dextrin and maltose are thus changed into dextrose. The solution is then brought into a 300 or 500 cc. flask, neutralised, diluted to the mark, and the dextrose determined with Fehling's solution. Supposing that the amount of dextrose obtained from 100 grms. of substance = D grms., the percentage of dextrin will be $0.9(D - 1.05m)$, as 20 parts of dextrose correspond to 19 parts of maltose.

(c.) As, according to Schwachhöfen, all dextrins have an acid reaction, it is useful to determine the acidity, which is done with 50 cc. of the solution, using phenolphthalein and decinormal potash.

In cases where the amount of insoluble starch is large, a correction should be made for the volume of the same. Assuming that the specific gravity of starch is 1.6, the number of cc. to be deducted is found by dividing the amount in grms. of insoluble matter in 25 grms. of the sample by 1.6, thus the volume for 40 per cent. of starch will be 6.2 cc.

The portion insoluble in cold water, which consists almost entirely of starch, is most conveniently estimated by mixing 2.5—3 grms. of the sample with 200 cc. of water and 15 cc. of hydrochloric acid of sp. gr. 1.125, and maintaining at a gentle boil for two hours, with an arrangement for preventing evaporation, then neutralising, making up to 300 or 500 cc., and testing with Fehling's solution. If D_1 grms. of dextrose are obtained from 100 grms. of substance the percentage of starch will be $0.9(D_1 - D)$. The water is determined by drying at 110°C. The difference between 100 and the sum of the maltose, dextrin, starch, moisture, and ash, gives the percentage of other organic matters.

The following results were obtained with this method:—

Sample.	Maltose.	Dextrin.	Starch.	Moisture.	Ash.	Other Organic Matters.	Acidity of 100 Grms. in cc. of Decinormal Potash Solution.
No.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	
1	4.25	47.78	35.55	10.11	0.27	2.04	40.0
2	10.90	36.75	43.20	7.02	0.39	1.74	26.6
3	3.75	29.46	58.00	6.85	0.60	1.34	25.3

—E. B.

On the Methods for Estimating Starch. A. v. Asbóth. Chem. Zeit. **13**, 591 and 611.

THE albuminoids in grain meal do not interfere with the baryta method of estimating starch (this Journal, 1887, 608), but the oil uses up some of the barium hydroxide. On this account the author recommends that 10 grms. of the meal (the amount of water in which is known) be first extracted with ether in a Soxhlet's apparatus, and then, after exposure to air to allow the ether to evaporate, crushed in a mortar. 1—1.8 grms. of the meal so prepared may be taken for the estimation of starch, and several grms. for that of moisture, which must be determined in order to calculate the percentage of starch in the original meal.

The above method gives higher results than Lintner's method, and this is due, according to the author's experiments, to incomplete solution of the starch in the latter method, for a residue is obtained which is converted into sugar by diastase.

Schrich (this Journal, 1889, 127) has asserted that the baryta method is not adapted for the analysis of rice, but according to the author is mistaken, for excellent results are obtained if the rice be first extracted with ether.—A. G. B.

The Determination of Glycerol in Crude Glycerin.

J. Lewkowitsch. Chem. Zeit. **13**, 659.

THE author has already shown that the tri-acetin process of Benedikt and Cantor (this Journal, 1888, 696), gives closely concordant results in the case of moderately pure "crude glycerins"; he now quotes figures showing a similar agreement with each other, for crude glycerins obtained by various methods of saponification, including that effected by the use of acid, and by the autoclave process. In the 24 numbers given, the maximum difference between duplicates is 0.58 per cent., and it is generally much less.

He also recommends its adoption in all cases where the glycerol is first isolated in a fairly pure state, as for instance, in its determination in fats and oils. In his recent examination of the fat of the Sawari nut, it was used with success, the fat being first saponified, the fatty acids liberated by means of sulphuric acid, the filtrate from them treated with barium carbonate, evaporated nearly to dryness, extracted with ether-alcohol, and the solution thus obtained evaporated first by gentle warmth and finally in a desiccator, leaving the crude glycerin; by then using the tri-acetin process it became unnecessary both to dry to constant weight and to determine the ash.

The author has tried the lead oxide method for the determination of glycerol, it having a certain vogue among English analysts, but considers it unreliable. (Compare O. Hehner, this Journal, 1889, 4—9.)—B. B.

Estimation of the Alkaloid in Coca-leaves. v. d. Marek.

Chem. Zeit. Rep. **13**, 144.

FIFTY grms. of the powdered coca-leaves are mixed with 20 grms. of calcined magnesia, triturated with water, dried at 60°, and extracted with ether. The ether is distilled off, the residue taken up with 2 per cent. hydrochloric acid, filtered, and the filtrate shaken with ether till no more colouring matter is extracted. The solution is then made alkaline with ammonia and shaken three times with 25 cc. of

ether. This ethereal extract is dried by calcium chloride, drawn off by a pipette, evaporated and the residue of alkaloid dried in a desiccator and weighed.—A. G. B.

On the Estimation of Organic Nitrogen by Volume, by Soda-Lime, and by Kjeldahl's Method. L. L'Hôte. Compt. Rend. **108**, 817—820.

THE author has made a series of determinations of organic nitrogen both by Kjeldahl's method and with soda-lime. Below are his results:—

	Theory.	Soda-Lime.	Kjeldahl.
	Per Cent.	Per Cent.	Per Cent.
Brucine	7.10	7.15	5.89
Cinchonine sulphate ..	7.46	7.42	{ 3.40 3.92
Asparagine	18.66	18.42	18.33
Caffeine	28.86	28.78	28.74
Oxamide	31.82	31.68	31.67
Uric acid	33.33	33.27	33.19
Urea.....	46.66	46.54	46.5

He draws the conclusion that Kjeldahl's method is by no means capable of universal application. He has also established the satisfactory nature of the soda-lime process, when used to determine organic nitrogen in urine and albumen, using as a check method that of Dumas. Cazeneuve and Hugonnet had impeached its accuracy as regards these substances.—A. R. D.

The Estimation of Organic Nitrogen by Kjeldahl's Method.

E. Aubin and L. Alla. Compt. Rend. **108**, 960—961.

IT is maintained that the physical conditions of many of the samples with which an agricultural chemist has to deal are such as to make the soda-lime process inconvenient or inapplicable. Kjeldahl's method, on the other hand, is employed in the greater number of the agronomic laboratories of France, which, alone, would seem to indicate its general usefulness. With regard to the brucine, sulphate of cinchonine, and urea referred to in a previous note, the authors explain that they had taken no pains to ensure the purity of the samples used in their analysis, which were only comparative, hence they must decline to accept the criticisms of L'Hôte, which are based upon the discrepancies between their figures and those yielded by theory.—A. R. D.

The Quantitative Estimation of Wood-Cellulose in Paper.

R. Godeffroy. Mittheil. des K. K. Tech. Gew.-Museums, 1888, 67—77, and 1889, 9—14. (See also under XIX., page 564.)

THIS is a continuation of the work commenced by Max Coulon and the author (see this Journal, 1888, 863—864) in connexion with a process of estimating the amount of ground wood-cellulose contained in paper, the process being founded on the property this substance possesses of reducing salts of gold.

As an average result of a number of tests it was found that 100 parts of purified ground pinewood cellulose, when boiled with gold chloride solution, reduced 14 parts of gold. The investigation of the reducing powers of the wood-cellulose of the ash, beech, poplar, willow, and fir, is in progress.

Wood-cellulose and the celluloses of straw, cotton, and linen in the chemically pure condition are incapable of reducing gold salts, but pure linen-cellulose reduces silver when boiled with a perfectly neutral solution of silver nitrate, no other of the celluloses mentioned above, if pure, being capable of effecting this change. A number of determinations were made to

ascertain whether linen-cellulose reduced a definite amount of silver. The linen-cellulose used in the experiments, after being repeatedly washed and finally dried at 100°, contained 1·71 per cent. of ash. Weighed quantities of the washed and dried cellulose were boiled for a few minutes in glass beakers with a neutral solution of silver nitrate, the linen-cellulose, coloured black by the reduced silver, was then brought on to a filter, washed, dried, and ignited. It is noteworthy that reduction does not take place with slightly acid solutions of silver nitrate, whilst alkaline solutions are reduced by the other kinds of cellulose as well as by linen-cellulose.

The following analytical results were obtained:—

Determination.	Amount of Linen-Cellulose taken.	Amount of Ash Calculated.	Weight of Silver and Ash Found.	Weight of Silver.	100 Parts of Linen-Cellulose Reduce of Silver.
	Grms.	Grms.	Grms.	Grms.	Parts.
1.	0·9686	0·06563	0·0302	0·01937	2·027
2.	0·9088	0·015540	0·0343	0·018760	2·064
3.	0·7886	0·013485	0·0304	0·016915	2·145
4.	0·8798	0·014944	0·0354	0·020456	2·325
5.	1·3076	0·022359	0·0490	0·026641	2·037
6.	0·7638	0·013090	0·0367	0·017610	2·305

It thus appears that 100 parts of linen-cellulose reduce as a mean 2·1 parts of silver.

Eight samples of paper made from mixtures of linen-cellulose and wood-cellulose were taken and analysed, after extracting with alcohol and ether, the results being calcu-

lated on the assumption that 100 parts of wood-cellulose reduce 14 parts of gold, and 100 parts of linen-cellulose reduce 2·1 parts of silver. The compositions of the papers were:—

No.	1.	2.	3.	4.	5.	6.	7.	8.
	Per Cent. 80	Per Cent. 70	Per Cent. 60	Per Cent. 50	Per Cent. 40	Per Cent. 30	Per Cent. 20	Per Cent. 10
Wood-cellulose								
Linen	20	30	40	50	60	70	80	90

The results of the determinations are given below, the calculations being made upon the weights of air-dried paper taken.

QUANTITATIVE ESTIMATION OF WOOD-CELLULOSE.

Paper.	Moisture.	Ash.	Extractive Matter.	Percentage found of		Total.
				Wood-Cellulose.	Linen.	
No.	Per Cent.	Per Cent.	Per Cent.			
1.	8·991	0·657	1·886	72·125
2.	8·751	0·645	1·702	61·102	27·410	90·610
3.	8·471	0·739	1·513	53·485	35·311	100·519
4.	8·278	0·817	1·433	43·996	45·612	100·166
5.	7·507	0·893	1·287
6.	7·121	1·026	0·994	24·414	64·769	93·627
7.	6·817	1·014	0·814	17·376	73·495	99·516
8.	6·444	1·099	0·733	..	80·794	..

A number of other determinations of linen and wood-cellulose in samples of paper made with linen and cotton rags, wood-cellulose, and china clay, gave satisfactory results.

It is pointed out that the previous results published are slightly incorrect, as no allowance was made for the presence of extractive matter, so that the percentages of wood-cellulose are slightly too high.

A sample of paper was prepared by hand from a mixture of equal parts of linen cellulose, and sulphite-cellulose.

The linen-cellulose, after being washed and extracted, contained 1·02 per cent. of ash; the extracted sulphite-cellulose 0·349 per cent. of ash. 100 parts of the linen-cellulose reduced 1·99 parts of silver from a solution of silver nitrate; the extracted sulphite wood-cellulose exhibited no reducing power either for silver or gold. The

paper was tested and gave the following percentage results: linen-cellulose 50·9, ash 2·08, matter extracted by alcohol, 2·399, matter extracted by ether, 0·834.

Different kinds of ground wood-cellulose, obtained as far as possible from various trees of the same age, and grown on the same ground, were tested with the results given below:

Kind of Tree.	Ash in Dry Unextracted Ground Wood-Cellulose.	Matter Extracted by Alcohol.	Matter Extracted by Ether.	Ash in Dry Extracted Ground Wood-Cellulose.	100 Grms. of Dry Extracted Ground Wood-Cellulose Reduce Gold in
Willow	Per Cent. 3·2115	Per Cent. 1·5845	Per Cent. 0·039	Per Cent. 3·1385	Grms. 13·94
Poplar.....	2·307	3·158	0·055	2·133	13·35
Elm	1·4855	1·690	0·020	1·458	13·65
Acacia	2·635	1·2575	0·0335	2·5535	11·347
Fir (pinus silvestris).....	3·7635	3·696	0·054	3·248	14·068
Pine (pinus abies)	1·1955	1·731	0·037	1·4305	14·226

Alkaline solutions of copper sulphate and of bismuth are reduced by extracted ground wood-cellulose, but a quantitative determination cannot be based on this fact. No other purified and extracted celluloses induce these reductions.

—E. B.

PATENT.

Improvement in Thermometer. C. U. Fisher, London.
From C. J. Tagliabue, New York, U.S.A. Eng. Pat. 5819.
April 5, 1889. 6d.

The object of this invention is to prevent the breakage of the thermometer should the case containing it be dropped. The case is open at both ends, each being provided with an elastic pad having a flange in the centre of its length considerably wider than the case. Each pad is so placed that one portion of it is inserted into the case, and abuts against the instrument, whilst another portion projects outside beyond the flange, which thus rests on the end. Should the case fall lengthwise it is protected by the flange, whilst should it drop endwise a like protection is afforded to the instrument by the pad.—E. S.

New Books.

DIE FABRIKATION DER THEERFARBSTOFFE UND IHRER ROHMATERIALIEN. Von Dr. W. HARMSEN. Berlin: S. Fischer Verlag, 1889. London: H. Grevel & Co., King Street, Covent Garden.

SMALL 8vo. volume, bound in cloth, price 10s., contains preface, table of contents, introduction covering the first seven pages, and subject matter extending to page 310. An appendix of a couple of pages and an alphabetical index conclude the work.

To give a precise idea of the nature of the contents of this little work it may shortly be said that whilst apparently designed as a text book for the student of chemical technology, the matter in it brings him still more closely in contact with the practical operations of the factory than is usual in works already written on this subject. If, for example, the text book of Noelting and Julius be regarded on the one hand as suited *par excellence* for the preparation of students in getting a theoretical grasp of the subject, then the work under present consideration may be regarded as complementary to it, supplying in concise outline the details of operation, apparatus, and plant. The text is illustrated with 34 wood engravings.

DIE CHEMIE DES STEINKOEHLENTHEERS. Mit besonderer Berücksichtigung der künstlichen Organischen Farbstoffe. Von Dr. GUSTAV SCHULTZ. Zweite vollständig umgearbeitete Auflage. Zweiter Band. Die Farbstoffe. Vierte Lieferung. Braunschweig: Druck und Verlag von Friedrich Vieweg und Sohn. London: H. Grevel & Co., 33, King Street, Covent Garden. 1889.

THIS, the fourth part of the second volume of what will be the most complete work ever written on the coal-tar colours, includes chapters thirty-seven to thirty-nine. CHAP. XXXVII. treats of the Alizarin colouring matters, Alizarin, Alizarin orange, Alizarin blue and Alizarin blue S., Alizarin W.S., Purpurin, Anthracene brown (Anthragallo), Flavopurpurin, Isopurpurin, Alizarin black and Galloflavin. CHAP. XXXVIII. treats of the Diphenylamine colours; there we find the Indophenols, Oxazines and Thiazines; whilst Chap. XXXIX. comprises the Eorholines, Safranines, Mauveïn, Magdala red, Neutral blue and Basile blue.

The text is illustrated by seven wood engravings and extended by numerous references to original sources of information. Very full references are also given to the more important sources of patent literature. The part, for volume it cannot be termed, commences abruptly with page 577, and ends with an unfinished sentence on page 768.

THE CHEMISTRY OF THE COAL-TAR COLOURS. Translated from the German of Dr. R. BENEDIKT, and edited, with additions, by E. KNECHT, Ph.D., F.I.C. Second edition, revised and enlarged. London: George Bell and Sons, York Street, Covent Garden. 1889.

ACCORDING to the preface of this work, designed principally for the student who desires to master the branch, as one of applied organic chemistry, two circumstances have combined to urge the translator and editor to the production of a second edition. Firstly, the appearance in the market, since the appearance of the first edition, of a large number of new coal-tar colours; and secondly, the increased scientific development of the subjects,—“the constitutional formulæ of many products of which we then (the period of the appearance of the first edition) knew little more than the empirical formulæ, having been definitely proved.” There is in this work, however, though as above stated, “principally designed for the student of applied organic chemistry,” a distinct practical direction, and this is perhaps rather towards the wants of the dyer than towards those of the colour manufacturer, though the latter must of necessity be acquainted with both classes of requirement. Part I. (pp. 5 to 68), for example, is devoted to “The Optical Properties of Colouring Matters,” “General Chemical Properties of the Colouring Matters,” “Methods of Dissolving the Colouring Matters,” “Dyeing with Coal-Tar Colours,” and “The Testing of Colouring Matters.” In Part II. the main subject is then commenced, “Coal Tar and the Raw Products used in the Manufacture of the Coal-Tar Colours;” and in Part III. attention is concentrated upon “The Coal-Tar Colours” themselves, arranged in the following

groups: (1.) Colouring matters from benzene and toluene. (2.) Phenol colouring matters. (3.) Naphthalene colouring matters. (4.) Anthracene colouring matters. The work, exclusive of index, now covers 325 pages.

COMMERCIAL ORGANIC ANALYSIS. A Treatise on the Properties, Proximate Analytical Examination, and Modes of Assaying the various Organic Chemicals and Products employed in the Arts, Manufactures, Medicine, &c. With concise methods for the detection and determination of their Impurities, Adulterations, and Products of Decomposition. By ALFRED H. ALLEN, F.I.C., F.C.S. Second edition, revised and enlarged. Volume III. Part I. Acid derivatives of Phenols, Aromatic Acids, Tannins, Dyes and Colouring Matters. London: J. and A. Churchill, 14, New Burlington Street. 1889.

As the author states in his preface, when the manuscript advanced towards completion, it became evident that the subject-matter would be too extensive to allow of publication of Vol. III. in one part. Consequently, the present issue forms Part I. of that volume, itself forming a large 8vo. volume containing 120 pages, and an independent alphabetical index.

The contents are as follows:—

ACID DERIVATIVES OF PHENOLS AND AROMATIC ACIDS.—Phenol-sulphonic acids; Benzoic acid; Cinnamic acid; Phthalic acids; Salicylic acid; Protocatechuic acid; Gallic acid; Tannins and Tannic acids. **DYES AND COLOURING MATTERS.**—Constitution of Colouring matters; Nitro-colouring matters; Nitroso-colouring matters; Aurin and its Allies; Phthalicins; Azo-compounds and Colouring matters; Rosaniline and its Allies; Safranines and their Allies; Anthracene Colouring matters; Sulphuretted and Unclassified Coal-Tar Dyes; Colouring matters of Natural Origin; Recognition of Colouring matters; Examination of Commercial Colouring matters; Examination of Dyed fibres. The work concludes with a table of Errata for Volumes I., II., and III.

Trade Report.

(From Board of Trade and other Journals.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Modifications in Customs Tariff.

Note.—Poud = 36 lb. avoirdupois. Funt = 902 lb. Gold rouble = 3s. 2d.

A despatch, dated the 19th June last, has been received at the Foreign Office from Mr. Audley C. Gosling, Her Majesty's Chargé d'Affaires at St. Petersburg, transmitting a statement notifying several alterations in the Russian Customs Tariff.

Notice is also given in the *Official Gazette* that various explosives, the importation of which has been hitherto prohibited, may now be imported by public institutions, companies, and private individuals, for agricultural, mining, signalling, and other purposes, with the sanction of the Minister of Finance and primarily of other authorities.

Section 243 of the Customs Tariff relating to such explosives is read as follows: (a.) Gunpowder.—Duty, 1 10 r. gold per pound gross. (b.) Dynamite and every kind of explosive substance and fulminating compounds, also all accessories for explosions, such as quick and slow matches, electric primings, &c., not specially mentioned in the tariff.—Duty, 3 r. gold per pound gross.

Section 45 of the Customs Tariff will henceforth be as follows:—

Starch in lumps and powder.—Duty, 1 10 r. gold per pound.

The new rates of duties are to come into operation from the date of their notification.

Notice is furthermore given that point 7 of section 26 and note 2 to section 153 of the tariff are modified, and are henceforth to be as follows, and that these modifications are to come into operation from the date of their notification in the *Official Gazette*.

Section 26, point 7. *Wax.* (a.) Bees wax, vegetable wax, wax for dressing trees, as also purified mineral wax (seresine).—Duty, 1 50 r. gold per pound. (b.) Mineral wax unrefined (ozokerite).—Duty, 40 copecks gold per pound.

A later report of Mr. Gosling, dated the 26th June, says that the *Messenger Officiel* contains the following notification modifying the Customs duty on paper pulp:—

Sections 25 of Customs Tariff, point 2, to be as follows:—

Section 25, paper pulp, point 2. (a.) Wood pulp, except pulp prepared chemically, 20 copecks gold per pound. (b.) Wood pulp prepared chemically (cellulose), though pressed, 25 copecks gold per pound.

At the same time the following rates have been fixed for paper pulp and its products when imported into Russia from the Grand Duchy of Finland:—

Paper pulp of every kind, except pulp chemically prepared, dry, 14 copecks gold per pound; paper pulp of every kind, except pulp chemically prepared, wet, 9 copecks gold per pound; cardboard of paper pulp, 20 copecks gold per pound; paper pulp prepared by chemical process (cellulose), though pressed, 25 copecks gold per pound.

Nematolite, agalite, asbestine, and similar products in fine powder and resembling asbestos in their composition, to be cleared (with the exception of ground tale, section 7) under section 145 of Customs Tariff.—Duty, 30 copecks gold per pound.

Notice is further given that the importation into Russia is allowed of ichtiola and salt of silpho (? sulpho), ichtiolic acid, but ready preparations of the same, such as solutions, ointments, pills, capsules, plaister, soap, &c. are prohibited, these being galenic preparations.

SWITZERLAND.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220 4 lb. avoirdupois. Franc = 9 $\frac{6}{10}$ d.

The following decisions, affecting the classification of articles in the Swiss Customs Tariff, were given by the Swiss Customs authorities during the month of May last:—

Acetate of soda, naphthionate; salt known as "Conservierungssalz" in open package.—Category 17. Duty, 1 franc per quintal.

"Phosgene" (solution of chloroxycarbonic gas in toluol and benzol).—Category 18. Duty, 2 francs per quintal.

SPAIN.

Classification of Articles in Customs Tariff.

Note.—Kilogramme = 2 20 1 lb. avoirdupois. Peseta = 9 $\frac{6}{10}$ d.

According to the *Deutsches Handels-Archiv*, the following decisions affecting the classification of articles in the Spanish Customs Tariff have recently been given by the Spanish Customs authorities:—

Unrefined mineral oils mixed with tallow are classified under Category 7. Duty, 41 cs. per 100 kilos., with a surcharge of 8 pes. 34 cs. and a transitory duty of 3 pes. 75 cs. per 100 kilos.

Resinous oils are classified under Category 58. Duty, 2 pes. per 100 kilos.

UNITED STATES.

Recent Customs Decision.

In the case of Castille soap and other commodities where the difference between the invoice weight and the weigher's return may be due to evaporation or other like causes, and

it appears to the satisfaction of the appraiser and collector that the foreign market value per pound of the goods landed has proportionally enhanced, so that there has been no diminution of the total entered value of the invoice in the foreign market, notwithstanding the shrinkage in weight, it would seem to follow that the foreign market value per pound would be represented by the result which would be obtained by dividing the total foreign market value of the invoice by the number of pounds landed. Article 604, Regulations, is modified accordingly.

CANADA.

Classification of Articles in Customs Tariff.

The following decisions affecting the classification of articles in the Canadian Customs Tariff have recently been given by the Canadian Customs authorities :—

Second-process molasses, testing by polariscope less than 35 degrees, when imported by manufacturers of blacking for use in their own factories in the manufacture of blacking, may hereafter come duty free under certain conditions.

Alizarine, blood albumen, arseniate, bi-arseniate, chlorate and stannate of soda, tannic acid, tartar emetic, chlorate of potash crystals, gum gedda, gum barberry, grey tartar, fustic extract, and quercitron or extract of oak bark, when imported by the manufacturers of cotton and woollen goods for use in their own factories only; and grey tartar, fustic extract, and quercitron or extract of oak bark, for the manufacture of colours, are admitted free of Customs duty until the end of the next session of Parliament.

Sulphate of alumina and alum cake, used as a substitute for alum by paper-makers, are placed on the list of articles that may be imported into Canada free of Customs duty.

Sumac, when imported to be used for dyeing or tanning purposes, *i.e.*, manufacturing purposes, not further manufactured than crushed or ground, is placed on the list of articles that may be imported into Canada free of Customs duties.

Camwood, when imported to be used for dyeing or tanning purposes, *i.e.*, manufacturing purposes, not further manufactured than crushed or ground, is placed on the list of articles that may be imported into Canada free of Customs duties.

Ferro-manganese, ferro-silicon, &c., entered for mixing with iron when smelted for castings, is allowed entry at the rate of 4 dols. per ton as iron in pigs.

SOUTH AUSTRALIA.

Drawback on Paint and Varnish.

A communication, dated the 13th May last, has been received from the Collector of Customs at Port Adelaide, South Australia, enclosing copy of an order of the Governor in Council, providing for the payment of drawbacks on paint and varnish exported from the colony, as follows :—

Paints mixed ready for use, manufactured in South Australia from materials upon which the full duty has been paid upon importation, provided that the proportion of oil used in the manufacture of such paint be not less than 33 per cent., will be entitled on exportation, and proof to the satisfaction of the collector of Customs of the correctness of the claim, to a drawback of 2s. per cwt.

Varnish manufactured from materials upon which the full duty has been paid in South Australia on importation, provided that the proportion of oil used in the manufacture of such varnish be not less than 33 per cent., will be entitled on exportation, and proof to the satisfaction of the collector of Customs of the correctness of the claim, to a drawback of 2d. per gallon.

Additional articles upon which no drawback will be allowed, unless in original packages or packed therefrom, in all cases upon the production of the original stamped invoices, *viz.* :—Blacking, blue, pickles, starch.

CHANGES IN THE FRENCH INDO-CHINESE CUSTOMS TARIFF.

The *Journal Officiel* publishes a decree of the President of the French Republic, effecting the following modifications in the Customs tariff of French Indo-China :—

Note.—Kilog. = 2·204 lb. avoird. Hectolitre = 92 imp. gallons. Franc = 9 ⁶/₁₀ d.

abolish or reduce the duties on the above-mentioned four fertilisers, and also on the following :—Phosphate of lime, nitrate of potash, nitrate of soda, sulphate of potash, silicate of potash, sulphate of copper, sulphur.—*Ibid.*

BRITISH BURMAH.

The Cutch Industry.

Next to rice, cutch is the most important article exported to Europe from Burmah. The cutch trade has become more and more important during the last 20 years, and although its prosperity received a temporary check in 1885-86, as a result of the annexation of the upper country, it has now fully recovered its former activity, and the production is as large as, if not larger than, that of previous years. And there is no doubt that in the same measure in which order and tranquillity increases throughout the country, and with the opening of new commercial routes, the manufacture of this product, which is so abundant in the forests of this country, will grow more and more. The cutch trees are found throughout the vast forests which cover the surface of Burmah. The wood has a dark red exterior, and much resembles mahogany. Cut into small pieces and boiled in water it is reduced to a paste called "Sha" in Burmese, which forms the cutch. This cutch is largely manufactured by the inhabitants of the villages fringing the borders of the forests. Cutchmaking is a very simple process, and only requires a pair of strong arms, an axe, and a vessel for boiling. In October, at the end of the rainy season, the Burmese go into the woods with their families in bands of three to six. By preference spots are chosen where clusters of strong and tall trees are found. Small holes are then cut in the earth, in which to place the vessels. Thereupon the trees are felled, hewn into logs, and peeled until the core is reached, which is immersed in water and boiled. As soon as the resulting paste has attained the requisite thickness it is emptied out on a mat and dried in the shade. The best qualities are next shaped into the tablets met with in commerce, and measuring 12 in. x 7 in. x 5 in. The colour of the cutch varies, according to the age or quality of the tree and the duration of the boiling process, from red or dark red to black. The bright red and red grades are considered the best, and are fashioned with much more care and in smaller tablets than the others. They are, along with betel and areca nuts, a favourite masticant of the natives. The dark red and black grades are especially made for the European and American markets, and it is these varieties that are bought up by the Rangoon merchants. Pure cutch, properly dried, should be of a regular and even shape, bitter and arid taste, and of a flavour resembling that of opium. The colour is more appreciated the nearer it approaches bright red. Enormous quantities of soft or elastic cutch are thrown on the market, because the boilers are in too great a haste to take advantage of a favourable market to properly dry the cutch. Some years ago the brand known as "*Mindoon pure cutch*," which excelled in uniformity of manufacture, was placed upon the market. A product locally named *Than-sha* is sold as an imitation of true cutch. It was first brought out about eight years ago, when it sold at 10 rupees per 100 "viss," but during the last season it has been worth 25 rupees per 100 "viss." Other varieties of cutch are mixed with fibrous matter, sand, or clay, or are prepared without regard to the quality of the wood or the boiling period. These grades are known as *Sal-sha*, *Naylan-sha*, *Revenoon-sha*, and *Pet-tok-sha*. Cutch mixed with sand or earth is easily known by weighing or tasting it. The Chinese never buy cutch from the Burmese without previously sorting it. The prices they pay run from 37 rupees per 100 "viss" for good hard cutch, to 20 or 30 rupees for soft grades, and from 25 down to 8 rupees for adulterated stuff.—*Ibid.*

CHINA.

China Root.

Nearly a quarter of the China root exported in 1887 from China came from Kiukiang, and the export in that year was below the average. It is grown principally in the

EXTRACTS FROM BRITISH AND FOREIGN CONSULAR REPORTS.

BRAZIL.

British Chemicals.

British trade with Santos has greatly progressed lately at the expense of that of Germany. Chemicals, hitherto exclusively derived from German sources, are now obtained from Great Britain in greater quantities, and preferentially. —*Chemist and Druggist.*

Chemical Manures.

For growing coffee it has hitherto been the custom to cut down the virgin forest, and when the woods and leaves become dry to burn them as they lie, thus adding natural potash to the already fertile humus. As the coffee tree only lasts about 15 years, estates without virgin forest are hardly saleable. The planters either move on to certain unvisited parts of São Paulo and Espírito Santo, which are being opened up by the Sorocabana and Leopoldina railways, or commence to use chemical manures. The latter course, however, is greatly impeded by the inconceivable height of duties on such fertilisers. The following four instances may be given :—On bisulphurate of carbon, price in France, 15*l.* a ton, the Customs duty here is 32*l.* a ton, without counting warehousing, Customs portorage fee, or 5 per cent. additional Customs dues. Sulphate of iron costs in France 2*l.* 16*s.* per ton, and pays taxes here 16*l.* per ton, without the additionals above mentioned. Sulphate of ammonia costs in Portugal 18*l.* per ton, and the Custom house here takes 40*l.* a ton. Superphosphate of lime, used for vines, coffee trees, cotton, and cane, costs 3*l.* a ton in France, and here pays 80*l.* duty, besides the extras above mentioned. In the Budget Law for 1889 the Government is authorised to

Chien-shan and Ho-shan districts in Anhui, and reaches the Yangtse at An-ching. To avoid lekin exactions it is brought to Kiukiang instead of Wuhu, and is shipped chiefly to Ningpo and Canton, from which latter port it is said 45,000l. worth is annually sent in the form of medicines to the Chinese in Australia and California. The exports from Kiukiang were 781,560 lb. (worth 13,547l.) in 1888, and 504,257 lb. (worth 8,048l.) in 1887.—*Ibid.*

Vegetable Tallow.

The export of vegetable tallow from Jui-ch'ang, the next district west of this, amounted this year to 517 tons, valued at 12,997l., or double the export of 1883 and 1884. It is reported that the natives are learning to adulterate it by mixing in kerosene or other cheap oil with the tallow while it is cooling. Chinkiang, Tientsin, and Peking take most of the tallow exported.—*Ibid.*

Cuttlefish.

There was a decrease in the exports in foreign vessels of cuttlefish from the Chinese port of Ningpo from 47,881 piculs in 1887, to 43,468 piculs in 1888; but it is believed that only about two-fifths of the take are exported in foreign vessels, the remainder going in junks to Wenchow, Fuhkien, and elsewhere. The fishing commences about April, and with the drying goes on till about June, when the market opens. The success of the trade is very dependent on the weather; a cloudy season interferes with the curing, north-east winds disperse the fish, and a mild winter naturally means scarcity of ice.—*Ibid.*

ECUADOR.

Drugs from Guayaquil.

The shipments of cinchona bark from the port of Guayaquil were larger in 1888 than in the previous year, the figures being:—1888, 880 quintals, value 2,640l.; 1887, 549 quintals, value 1,647l. Nearly the whole of this went to England. Of Condurango 8,250 lb. were shipped, of which two-thirds to England and most of the remainder to Germany; and of sarsaparilla 20,365 lb. to England and Chili.—*Ibid.*

FRANCE.

The Marseilles Oil Trade.

The total imports of seed oils in Marseilles in 1888 attained 278,527 tons, against 286,770 in the previous 12 months; the falling off has been chiefly in gingelly seed from Bombay, owing to the small crops there. The general state of trade improved considerably during the year, as, by reason of the shorter supplies and substantial rise in tallow and all greases, prices of seed-oil rose considerably, and there was a steady sale during the last six months. For 1889 the general opinion inclines to lower values, as the crops of ground-nuts on the Madras and Coromandel coast promise large yields, and the Bombay crops are also full average ones. Under oleaginous seeds are also comprised palm kernels and coprah, which produce concrete oil, and form one of the principal ingredients in the manufacture of soap, which is made of about 30 per cent. concrete oil and 60 per cent. to 70 per cent. seed-oils. Coprah gives about 65 per cent. oil, and palm kernels about 44 per cent. Nearly the whole of the said imports of oil-seeds, viz., 278,527 tons, have been crushed by Marseilles crushers, giving a production of 100,000 to 110,000 tons of oil. These products are connected with one of the largest and most prosperous industries in Marseilles, viz., the candle and stearine factories of Messrs. Les Fils de Frederic Fournier, who are among the very largest manufacturers in Europe, their production of stearine amounting to nearly 1,200 tons yearly, and about 16,000 tons of candles, stearine, and tallow. The chief articles used for this production are palm oil and tallow, and their imports for these for 1888 have amounted to 11,551 tons palm oil and 4,195 tons tallow, in addition to common greases and French home-melted stuffs.—*Ibid.*

MOROCCO.

Cumin Seed.

A good deal of cumin seed is produced in the districts near the city of Morocco (Marakesh in the vernacular), and in addition to being much used by the natives, both Mohammedan and Israelitish, in cooking and confectionery, is an article of export, the value for the year 1888 being quoted at 708l. for 21½ tons of this small grain, shipped to England, France, and Spain.—*Ibid.*

Olive Oil.

The 1888 yield of this oil from the Mogadore district was considerably below that of 1887, and as the prices obtainable on the European markets were by no means encouraging, a considerable proportion of this yield appears not to have been shipped, but to have been stored in the interior, in hopes of better times.—*Ibid.*

Argan Oil.

The oil produced from the kernels of the bitter berries of the argan tree (*Argania sideroxylon*), forests of which form an interesting and peculiarly characteristic feature of the landscape in Southern Morocco, is of universal use in these parts for lighting and cooking purposes. The rank smell and taste which characterise the raw oil disappear entirely at a certain degree of heat, imparting no disagreeable flavour whatever to food properly cooked in it.—*Ibid.*

RUSSIA.

Russian Quicksilver.

Our Consul at Taganrog (Black Sea) mentions that the quicksilver mine in his district, of which mention was first made in the year 1886, has been successfully worked in 1888, 32,300 tons of ore having been extracted; 32,800 tons were sorted, of which nearly 30,000 tons contained quicksilver, averaging from 0.44 to 6.90 per cent. The latter quality is rare; only 1½ per cent. of the ore gave such high results. About 28,500 tons were calcined, and yielded 3,234 cwt. of clean quicksilver. In 1887, the first year, only 1,266 cwt. were produced. This Russian quicksilver is remarkably pure, and has supplanted all foreign importations.—*Ibid.*

MISCELLANEOUS TRADE NOTICES.

IMPORTANT SALT DISCOVERY AT BARROW.

The find of salt on Walney Island over a large area is viewed with some apprehension by the Salt Syndicate. The quality of the deposit is excellent, and it is in the hands of a small syndicate, which will first consider the interests of this town before entertaining any proposals from the Union for keeping up prices. The price of salt has gone up quite 75 to 80 per cent. to consumers; but it is hoped that the Walney discovery will bring it down considerably, and at the same time furnish cargoes for ships bound for the East.—*Chemist and Druggist.*

PRONUNCIATION OF CHEMICAL TERMS.

A committee, consisting of Professor Thos. H. Norton, Professor Edward Hart, and Professor H. C. Botton, appointed by the Chemical Section of the American Association for the advancement of Science, to report on the question of uniformity in the pronunciation and orthography of chemical terms, are desirous of obtaining from the chemists of America a full expression of opinion on the more important questions where usage is uncertain or variable.

With this object in view, the committee have sent a list of the more important and typical words used in chemistry, based largely on one compiled by Professor J. H. Appleton,

of Brown University, modified, however, by numerous additions and by the omission of all names of minerals. The pronunciations given are those of standard dictionaries, but are in no sense to be regarded as recommended by the committee; they serve rather as a guide to uniformity in the manner of indicating pronunciation.

It is hoped thus, through the co-operation of chemists, to obtain, by this means, a valuable fund of material, showing the prevalent feeling and usage with regard to orthography and pronunciation, which will serve as the basis for definite recommendations to the Association, and later for propositions leading to unity of action with the chemists of Great Britain.

Among the names which the committee have included in the circular that they issue are the following:

Aluminium, which they pronounce al-ū-mīn'i-um, which we believe to be far less desirable than "aluminum"; anadgam, a-nad'gam; anode, an'ōd; apparatus, ap-pa-rā'tus; argillaceous, ār-jil-lā'shus; arsenic, ār-sen-ik; asbestos, az-bes'tos; asphalt, asfalt; assay, as-sā; auriferous, āu-rif-er-us; barium, bā'ri-um; basic, bā-sik; bismuth, biz'muth; boron, bō'ron; centigrade, sen-ti-grād; centimeter, sen-ti-mē'ter; chromium, krō'mi-um; cobalt, kō-bālt; concentrated, kon-sen-trāt-ed; crystalline, adj., kris'tal-in; crystallography, kris-tal-log'ra-fi; delugating, def-la-grāt-ing; didymium, di-dim'i-um; dilute, di-lat'; distillation, dis-til-lā'shun; ebullition, eb'ul-li-shun; electrolytic, e-lek'trol-it'ik; endiometer, ū-di-om'et-er; Fahrenheit, fā'ren-bit; fluorine, flū'or-in; gangue, gang'; gaseous, gaz'e-us; gelatin, jel'at-in; gelatinous, jel-at'in-us; halogen, hal'ō-jen; hydrochloric, hī-drō-klō'rik; hydroxide, hī-droks'id; hydroxyl, hī-droks'il; indium, in'di-um; iridium, i-ri'di-um; isomerie, i-sō-mer'ik; isomerism, i-som'er-izm; kupfernickel, kup'fer-nik-el; lanthanum, lan'than-um; liter, lē-tēr; litharge, lith'ar-j; lixiviation, liks-iv'i-ā'shun; magnesium, mag-nē'shi-um; manganese, man'gan-ez; mercuric, mer-kū'rik; mercurous, mer-kū-rus; metallurgy, met'al-er-j; meter, mē'tēr; millimeter, mil'li-mē-tēr; molecular, mol-ek'u-lēr; molecule, mol'e-kūl; molybde, mol-ib'dik; molybdenum, mol-ib-dē-num; monad, mon'ad; nickel, nik'el; osmium, os'mi-um; oxide, oks'id; palladium, pal-lā'di-um; paraffin, par'af-in; platinum, plat'in-um; polymerism, pol-in'er-izm; potassium, pō-tas'si-um; quinine, kwīn'in; réaumur, rā'ō'mūr; rhodium, rō'di-um; rubidium, rō-bid'i-um; ruthenium, rō-the'ni-um; selenium, sē-lē'ni-um; stoichiometry, stōi-ki-om'et-ri; strontium, stron'shi-um; sulphurous, sul'fer-us; tantalum, tan'ta-lum; tellurium, tel-lū'ri-um; terbium, tēr'bi-um; tetrad, tet'rad; tetratomic, tet-ra-tom'ik; thallium, thal'li-um; titanium, ti-tā'ni-um; titer, tīt'r; titrate, tīt'rāt; titration, tī-trā'shun; tungsten, tungs'ten; uranium, ū-rā'ni-um; valence, val'ens; vanadium, van-ā'di-um; ytterbium, it-ēr'bi-um; yttrium, it'ri-um; zirconium, zēr-kō'ni-um. — *Engineering and Mining Journal*.

PROTECTION AGAINST ACCIDENTS BY EXPLOSIVES IN NEW YORK.

A new series of regulations to govern the manufacture, transportation, sale, storage, and use of explosives within the limits of the city of New York has been issued by the Fire Department. These regulations have been drawn up by a committee consisting of General Fitz John Porter and S. Howland Robbins, Commissioners, with Carl Jussen as secretary and J. H. Striedinger, C.E., as expert.

In the explanatory notes, giving a classification of what are termed high explosives, viz., those that are more sudden and violent in their action and effect than gunpowder, and in the notes on the properties of certain high explosives, is to be found much information useful to all whose business brings them into contact with such materials.

The most important and well-known of these "high explosives" are the following:—

Nitro-glycerin, pure and simple. Dynamite, with explosive base, like dynamite or giant powder No. 1. Dynamites, with explosive base, like "Rendrock," "Vulcan powder," "Atlas powder," "Hercules powder," "Dualin," and "Judson powder." Explosive or blasting gelatin. Gelatin dynamites, like some varieties of "Foreite." The foregoing

are all nitro-glycerin mixtures. Gun-cotton, pure and simple, or prepared as tonite. Pierates, such as "Designolle" powder and pierie powder. Chlorates, like "Raekaroek." Sprengel's group of modern explosives, also called pan-elastites. Fulminates of mercury and of other metals.

The manufacture of all such explosives, gunpowder included, is forbidden within the city limits, and the regulations as to packing for transportation, transportation itself, sale and storage for sale, are such that, if properly observed, no explosion of a really dangerous character can take place. The permits for use, location and nature of magazines, are also well guarded, the applicant having to state in writing the proposed location, depositing a plan of the building, and furnishing a bond for 5,000 dols. for the payment of any loss, damage, &c. The permits are only for 12 months, non-transferable, and subject to revision and amendment at any time.

The restrictions limiting the amounts kept in main magazines, which must be well and substantially built of brick, stone, or concrete, or excavated in solid rock, earth, or mine refuse not liable to take fire, are reasonable, and, while protecting the public, offer no real impediment to business. The amount that may be kept in a main magazine, if not less than 50 yards from the nearest protected structure of the first class and 100 yards from the nearest protected structure of the second class, is 500 lbs. of blasting powder, or half that amount of high explosive. When the above distances are increased to 75 yards and 150 yards respectively, the amount may be increased to 1,120 pounds of blasting powder, or half that amount of high explosive. One very necessary and important regulation is that no detonators shall be kept in a high-explosive magazine. The definitions of protected structures of the first class comprise all buildings used for dwelling or manufacturing purposes, workshops, furnaces or fire-places for boilers, engines or other machinery, provided the same are occupied by the licensee, or that the persons occupying them consent in writing to the proposed location of the magazine, which consent shall be filed with the application for the permit. All highways, roads, streets, or avenues, open places of public resort, canals, and other navigable waters, docks, piers, sea-walls, or reservoirs, are also comprised in this class.

Protected structures, &c. of the second class comprise all structures, &c. not in the first class, and also all buildings used for religious, educational, charitable, or public purposes, or for purposes of amusement or instruction.

The directions for the use of explosives in blasting operations are so clear and sensible that we print them in full in another column, along with the notes on the properties of some of the high explosives.—*Engineering and Mining Journal*.

EXPLOSIVES REGULATIONS FOR THE CITY OF NEW YORK.

Directions for use in Blasting.

The cartridges delivered to the men shall be protected by them against frost, moisture, fire, and contact with iron, steel, or grit.

It is forbidden to use cartridges frozen or only partly thawed out.

It is forbidden to warm frozen cartridges by direct exposure to fire, by keeping them before fire-places, by putting them on stoves or in ovens, or by laying them on hot ashes.

1. It is required that frozen cartridges shall be returned to the foreman in charge and shall not be reissued for use until thoroughly thawed out.

2. It is required, in thawing out frozen high explosives, that one of the two following methods shall be observed, the first being the safest and most practicable for large quantities and therefore preferable:—

Put the boxes containing the explosives in fresh horse manure, or entirely surround the magazine therewith.

Put the cartridges in a double vessel consisting of two watertight tin kettles or pots, so made that one shall fit inside of the other and leave a space for water (which must be lukewarm) between the buttons and sides.

It is forbidden to attempt to break or cut cartridges entirely or partly frozen.

It is forbidden to prime more cartridges with fuses and detonators than are actually needed at the moment, or to keep on hand such primed cartridges.

It is forbidden to use metallic rammers in tamping drill-hole charges.

It is forbidden to "bring home" the tamping by powerful strokes.

It is forbidden to introduce into a drill-hole more than one primer, or to roughly handle the primer, especially while placing it on the top of the charge, or while tamping it.

It is forbidden to approach a drill-hole charge which failed to explode without waiting at least 10 minutes, counting from the time of setting fire to its fuse.

It is forbidden to remove the tamping of a charged drill-hole.

It is required, in case an attempt to fire a "missed blast" by means of exploding a strong primer on top of it is unsuccessful, that a new hole be drilled not nearer than 12 inches from the first one, and a fresh charge put in (that being the safest method), the explosion of which will probably be communicated to the first charge, or if it is not, will at least dislodge it. But the distance between these holes must be increased if there is any reason to believe that the nitro-glycerin mixture of the first charge has spread laterally.

It is forbidden, in case the explosion of a charge does not carry away the whole drill-hole, leaving the lower part intact, to use the remaining part of the old drill-hole as a starting point for a new drill-hole; because portions of the former charge may remain and explode when exposed to the blows of percussion drills.

It is forbidden to allow boys under twenty-one (21) years of age, or men who cannot read English, or are untrained in the care of high explosives, to be in the vicinity of hand magazines or handle such explosives.

It is required that, to ensure the safety of surrounding property and of persons in the vicinity, no larger charge shall ever be used than is necessary to properly start the rock.

It is required that rock excavations contiguous to any structure shall be so carried on as not to cause any damage to such structures. To secure this, weak walls, &c. of such structures must be shored up, and all rotten or decomposed rock must be removed by the use of gads, picks, and crowbars only. When blasting next to such structure is unavoidable, light face blasts only, with short lines of resistance and small charges, shall be used.

It is required that only careful, reliable, and thoroughly experienced foremen shall be employed in blasting operations.

It is required that in the neighbourhood of roads, houses, and objects which may be damaged by blasts, the shots shall be carefully covered (preferably with brush mattresses, facines, and the like), and the charges shall be so reduced in size that no flying about of debris shall be possible. Red flags shall be placed at reasonable distances from the blast on all sides; a whistle shall also be blown, or a bell rung, five minutes before the explosion takes place, to give all persons proper warning. Men shall also be stationed at the doors of houses in the immediate vicinity and on the different highways and sidewalks, to caution all persons against approaching the blast.

Notes on the Properties of certain High Explosives.

Pure nitro-glycerin, at 60° F., has a specific gravity of 1.6. It is odourless, nearly colourless, and has a sweetish, burning taste. It is poisonous. Handling it is apt to cause headache. It is slightly soluble in water. It will explode when heated to a temperature of about 356° F.

These properties undergo no change when nitro-glycerin is absorbed by other substances, in forming nitro-glycerin mixtures or dynamites such as those enumerated in the paragraph defining the term "high explosives."

The temperature at which nitro-glycerin mixtures freeze varies from 39° to 50° F., according to the difference in the methods of manufacture and the quality of the nitro-glycerin used. The use of such substances as silicious marl ("Kieselguhr") as an absorbent in the manufacture

of dynamite and giant powder No. 1, undoubtedly hastens their freezing.

Reliable experiments made in Austria show that frozen nitro-glycerin mixtures are less liable to explode from mechanical shocks than when they are not frozen.

When, however, the nitro-glycerin mixture is in a partly frozen condition, or when it is either in process of freezing or of thawing, its sensitiveness to explosion is greater than when in its normal condition, and it is then especially liable to be exploded by repeated light shocks, such as are produced in the operation of packing, transportation, &c. The experience both of the laboratory and of the factory confirms these views.

As before stated, nitro-glycerin mixtures explode at a temperature of about 356° F. They also explode by percussion, concussion, friction, pressure, &c., viz., by any act converting mechanical energy into heat.

By the use of fulminate of mercury caps as an initiatory explosive, the entire mass of nitro-glycerin mixture is converted into gas with such suddenness that it may practically be considered instantaneous; this sudden effect is termed "detonation."

In dynamites containing a large percentage of nitro-glycerin, the latter is liable to exude, or ooze out. This is especially so in warm weather or in thawing out at high temperatures.

Exposure to water is injurious to dynamites. In the high grades the water, by its great affinity for the inexplorable absorbent (Kieselguhr), drives out the nitro-glycerin; in the lower grades it is apt to dissolve the salts (nitrates of potash or soda, &c.) contained in the explosive absorbent, thus setting free the nitro-glycerin.—*Engineering and Mining Journal*.

OIL OF LEMON AND LEMON-JUICE IN SICILY.

In a recent report on the manufacture of lemon-juice and essential oil of lemons in Sicily it is stated that with all classes of lemons the yield of juice and its acidity varies considerably from month to month. The amount of juice increases from October to April, but its acidity and density decrease, and the same is the case with the density of the essence, owing to the winter rains. Raw and concentrated lemon-juice is exported in casks of 130 gallons capacity. It requires 1,500 lemons to yield 26 gallons (1 hectolitre) of raw juice, and 2,500 to yield the same quantity of concentrated juice, and about 200,000, according to their acidity, to give a cask. The lemons of the province of Messina, especially from the Eastern shore, contain more acidity than the lemons grown elsewhere in Sicily. The value of lemon-juice is governed by its acidity. The rule is that concentrated lemon-juice shall show 60 degrees of acidity, while the juice extracted from the bergamot or the sour orange must show 48 degrees, or one-fifth less than that derived from the lemon, and it also sells for one-fifth less than lemon-juice. Formerly a citrometer, known as Ronchetti's gauge, was used to ascertain the percentage of acidity; now, however, resort is had to chemical analysis, which is more satisfactory both to seller and buyer. Lemon-juice is used in the printing of calicoes, and for many other purposes. Of late years a new article, known as vacuum-pan concentrated juice of lemon, has been manufactured in Messina. The juice concentrated by this method contains 600 grains of crystallisable citric acid for every quart. It is exported in casks containing 112 gallons, in half and quarter casks. It is also shipped in bottles of 500, 300, and 150 grains each. This concentrated juice is as limpid as first quality oil. There is an establishment in Messina, probably the only one of its kind in Italy, that prepares crystallised citric acid. It takes from 340 to 380 lemons to make a pound of citric acid. The following is the process of preparing essential oil of lemon. The lemons are peeled lengthwise with a sharp knife, and the peel dropped into a tub under the chopping-block. The peeler then cuts the lemon in two and throws it from his knife into a bucket. He fills from 10 to 12 tubs with peel a day, and is paid 2½d. for a tub weighing 77 lb. The fresh peel is soaked in water 15 minutes before the essence is extracted. The operative holds a small sponge in his left hand, against which [and the *cevrille*?] he presses the epicarp of each piece of peel

two or two times, simple pressure followed by rotary pressure. The women employed in this work run a piece of cane through their sponges to enable them to hold them more firmly. The sponge when saturated with the essence is squeezed into an earthenware vessel which the operative holds in his lap. He is expected to press the peel so thoroughly as not to overlook a single cell. This is ascertained by holding the pressed peel to the flame of a candle, when it should not crack. The essence is skimmed off, bottled, and left to settle for a few days. It is then drawn off with a glass syphon into coppers, which are hermetically sealed. The expressed peel is used as a cattle food, or left to decompose and employed as a fertiliser. The industry is carried on five months in the year. Immature fruit contains most oil. From November to April, in the province of Messina, 1,000 lemons yield about 14 oz. of essence and 17 gallons of juice. An operative expresses about 190 lb. of lemon-peel a day, for which he is paid about 2s. 6d. Six men can work about 8,000 lemons a day; two cut off the peel while four extract the essence, and obtain 136 gallons of lemon-juice and 7 lb. of essential oil. In a bergamot-distilling establishment in Reggio, on the mainland, a hand machine for extracting essential oil is used. The skin of the unpeeled bergamot is punctured by a system of revolving knives and then gently pressed. It should be borne in mind that the bergamot is spherical in shape, and this machine could not therefore be used for lemons. A thermopneumatic essence extractor, worked by steam-power, has also been invented, but the old system is still in general use in Sicily on account of abundant and cheap labour. The method employed for the extraction of essential oil from the lemon applies also to the sweet and sour orange, the bergamot, and the mandarin.—*Chemist and Druggist*.

THE FOREIGN TRADE OF MADAGASCAR.

The following statistics of the trade of Madagascar for the year 1888 are extracted from the *Journal Officiel* for the 17th June last:—

The total value of the exports was 4,119,234 francs. The principal article of export is hides, valued at 1,760,801 frs. Then come caoutchouc, with a value of 1,366,211 frs.; rafia, valued at 441,079 frs.; wax, worth 280,243 frs.; and oxen assessed at 244,044 frs.

Articles were imported to the value of 4,050,779 frs. Textiles, with a value of 1,788,540 frs., constitute nearly one-half of the value of the total imports.

PRODUCTION OF PETROLEUM IN GALICIA.

The *Revue de l'Orient* gives the following account of the production of petroleum in Galicia:—

The most important springs of petroleum are found in the region of the Carpathian Mountains, and along the chain of those mountains, from Gryhow in the west to the frontier of Moldavia on the east. The annual product amounts to about 600,000 casks, that is to say, more than 90,000 tons. The system of working most generally in use is the Canadian system of tapping. The setting up of a complete system of tapping does not cost 1,000*l*. The most important centres are Bobz, where there are 42 production wells with a total yield of 2,000 casks a day—that is to say, 318 tons of petroleum; Vietzno, with one well yielding 200 casks; Vastova, which gives the best quality and the richest oil, containing 70 per cent. of oil for lighting purposes; Kryg, Lipinki, and Sloboda. The specific gravity of these qualities of petroleum varies from 0.92 to 0.79. Refining takes place by means of distillation, principally in order to obtain lamp oil. In several distilleries nothing is preserved except the first produce of the distillation, that is to say, only what is obtained at a low temperature. The remainder, especially the liquid tar, is taken elsewhere to undergo a second process of distillation. In other refineries the process is pushed as far as it will go at first until there is nothing left in the retorts but coke or cinder. At 40° the distillation gives a brownish-yellow benzene, which becomes whiter and whiter until 150° is reached. Between 150° and 300° various light oils are obtained which, subjected to a second distillation, produce lamp oils; beyond 300° those heavy oils are met with, from which fatty substances and paraffin are extracted.

The lamp oils, on leaving the retorts, cannot immediately be distributed to the trade, being as yet neither homogeneous nor pure. They are subjected to a treatment with sulphuric acid and a solution of soda. The acid serves to remove the resinous parts, while the solution of soda removes any excess in the acid. As to the paraffin, this is commonly extracted from gross oils of a green colour, having a density of 0.91. It is deposited in the form of a thick, mucous mass, which is collected in canvas sacks to be then compressed by hand, or with hydraulic or steam presses.

Among the principal refineries, that of Libuzza takes the first place. It produces several qualities of petroleum: "standard white," at 22 frs. 50 the quintal on delivery at Jagorzany; "prime white," at 33 frs. 75; "superfine white," at 25 frs.; "water white," at 26 frs. 25. The price of the cask is 3 frs. 75 and above per quintal of petroleum. Examined against a black background, the "standard white" is yellower than the "prime white"; looked at against the light it has the colour of an opal. The "water white" is perfectly translucent, and looked at against the light appears slightly bluish. The "standard" marks 47° R., and the firing point is 23°. This is the petroleum most generally used for lighting purposes and in commerce. In this Libuzza refinery the raw petroleum of the Kryg, Libuzza, and Lipinki regions are treated. At the Kolomea refinery the petroleum of those of Hoboda and Rofa.

It is found that Galician petroleum burns best in lamps with a diametrical wick, while the American petroleum gives more satisfaction when used with a wick of circular form. A comparison of the yield in refined petroleum of various quantities of petroleum from different countries gives the following result:—

- 100 kilos. of Russian raw petroleum gives 45 per cent. of refined petroleum.
- 100 kilos. of Galician raw petroleum gives from 50 to 52 per cent.
- 100 kilos. of American raw petroleum gives from 60 to 63 per cent.

THE TRADE IN MASTIC.

The *Journal de la Chambre de Commerce de Constantinople* for the 22nd June last has the following note with reference to the trade in mastic:—

The Administrative Council of the island of Chio recently made a study of the best means of raising the price of mastic, which had remained at a low price for several years. Among other measures it was decided to prohibit:—

1. The repeated incisions in the trees.
2. The offering for sale of impure, yellow, or black mastic.
3. The mixing of this native product with dust or with residues of the tree bark, more or less impregnated with mastic.

Since these salutary measures have been adopted and carried out, the price of the mastic has advanced to an appreciable extent, and the Government of the island informs the commercial world that, for the future in respect of this article:—

1. The bark of these resinous trees must not be tapped more than twice a year, and that at fixed and determined periods.
2. There must only be gathered the white mastic, free from powder or from any other foreign substance.

THE ADULTERATION OF CITRONELLA OIL IN CEYLON.

The *Ceylon Observer*, with reference to the adulteration of citronella oil in Ceylon, says:—

"A correspondent (evidently a native) reported as follows to a contemporary some little time ago:—

"A few weeks ago about 650 cases of kerosine oil were taken to the Weligama Custom house by boat, either from Galle or Colombo. Of these about 500 cases were taken to Matara, Akurassa, Weligama, and Kumburupitiya. It is highly improbable that such a large quantity of kerosine oil would be used for lighting purposes by the people of those districts. The reason for such a large consignment of kerosine oil is easily explained. Kerosine oil is now being largely used for adulterating citronella oil, and so

there is now a large demand for it. Villagers in the places mentioned may be seen conveying kerosine oil to places where citronella oil is stored, the two oils are then mixed in certain proportions and sold to several European firms in Galle and Colombo as good citronella oil. If European merchants think that the citronella oil as supplied them by their contractors, and that supplied direct by the proprietors of citronella estates, are the same, they make a great mistake; for the oil supplied by proprietors and manufacturers is pure and free from any adulteration. It will now strike European merchants as strange that, in the contract which they entered into between themselves and the contractors, there is generally a conditional clause to the effect that the oil supplied by contractors will be *market oil*. If any dissatisfaction is ever expressed by a merchant as regards the oil thus supplied, the contractors' plea is that it is market oil, and they are not responsible for its quality; but such an excuse could not be made by a proprietor."

"We asked the opinion, on this subject, of perhaps one of the best authorities in the island, at least of those resident in citronella-planting districts, and he reports as follows:—

"Some five years ago I took a trip to the principal citronella-producing district to investigate this very matter, and was much surprised on being told by one of the largest buyers of this oil that the great bulk of citronella was largely adulterated with kerosine. Indeed, he said that up to 25 per cent., detection, so far as he knew, was impossible. The increase of cultivation since then has been out of all proportion to the increase of citronella exportations, while a large acreage of the old grass must by this time be decreasing in yield; therefore, I do not doubt that the adulteration is increasing in proportion.

"Lately, at Nuwara Eliya, I met a gentleman from England, who is a large buyer of Ceylon citronella oil, who informed me that he could not get it pure in the market."

THE PRODUCE OF LAGOS.

In a letter to the African Trade Section of the Liverpool Incorporated Chamber of Commerce, his Excellency C. A. Moloney, C.M.G., Governor of Lagos, referring to various specimens of the products of Yoruba which he had brought from Lagos, and which he had left with the Chamber at Liverpool, says:—

"*Gum*.—Specimens about $\frac{1}{2}$ cwt. each. These are really resins. Much inferior samples have been valued in England at 96*l.* to 120*l.* per ton.

"Trade has made a start at Lagos in this commodity, small consignments having realised from 40*s.* to 50*s.* per cwt.

"There is room for a considerable development of this industry. Yoruba abounds in the article.

"The native name '*ogea*' is generally applied to gum, as is '*ibo*' to rubber.

"The tree yielding this resin has been given by Professor Oliver, of the Royal Gardens, Kew, as a *Daniellia*, and will probably prove a new species.

"You have also with you two or three small samples of gum I got at Benin; it is deeper in colour and somewhat different in smell from the Yoruba '*ogea*.'

"*Rubber*.—Rubber is in its infancy in the colony of Lagos. We have there several *Landolphas*, which yield the best white rubber of commerce. In view of the success of this industry in the Gold Coast Colony within six years, Lagos bids fair to rival the sister colony before long.

"Interesting experiments on the *Abba* juice have been made by Mr. Alvan Millson, Commissioner of Badagry, which were fully published in the Government *Gazette*. He deserves considerable credit for his efforts in the direction of promoting the economic botany of his district. This industry requires greater attention and persistent efforts put forth.

"*Cocoa-nut Industry*.—Lagos offers a fair field for the establishment of an oil-crushing business conducted on a small scale at first. Cocoa-nuts can be there purchased, as they fall from the tree, at 2*s.* to 2*s.* 6*d.* per 100,

"In connexion with any cocoanut-crushing business, an addition with profit might be made by associating with it the preparation of fibre, in which Yoruba is rich. As examples—

"*Coir*.—You have some samples roughly prepared in the Lagos gaol. It has been divided in England into three samples, as is required by the trade, which have been valued respectively at 10*l.* to 11*l.* per ton, 18*l.* to 19*l.* per ton, and 29*l.* to 31*l.* per ton.

"*Sausieria Guineensis*.—The Yoruba name for this commodity is '*ojathoka*,' which is generally indeed applied by Yorubas to *Sausieria* fibre. West Africa is rich in species. I had some fibre roughly prepared in the gaol from the *Sausieria Guineensis*. It unfortunately arrived damaged, and, notwithstanding, has been valued at 15*l.* per ton. I am informed that, if properly prepared and carefully shipped, it should realise from 20*l.* to 30*l.* per ton. Samples are at Liverpool.

"*Honkenya Ficifolia (Tiliaceae)*.—This is a jute-like fibre, and might be cultivated to any extent in Yoruba. Samples sent to England have been valued at 16*l.* to 17*l.* It compares favourably with Indian jute. The native name of this plant is '*bolobolo*' in Popo, and in Yoruba, '*Aghorin Ilasa*.'

"You have also another tiliaceous fibre, native name Toja, closely allied to the *bolobolo*, which has been valued at 17*l.* to 18*l.* per ton. This plant is capable of extensive growth, and deserves attention.

"Next you will notice a large bunch of grass-like fibre, composed of epidermal strips of the leaves of the *Raphia vinifera*, or what is commonly called *bamboo*. In 1886, Messrs. Cross and Bevan, consulting chemists, London, called special attention to this yield, and said it should command a high price amongst gardeners and nurserymen, as did Madagascar *rafia*. I left with you a bunch of West African *rafia* dyed black.

"The *white clay* (used for personal adornment—I should say disfigurement—in Yoruba) comes from Okeodan, behind Badagry, and may deserve attention. Could it be put profitably to any use at home? The leguminous pods are seeds used medicinally by the natives.

"There are also samples of camwood and barwood (*Baphia nitida*) from Benin river, and a native mangle of country wood sent to me as ebony.

"*Indigo*.—Yoruba land is famous among West Africans for its blue dyeing. Over it are found many botanical species that yield the indigo of commerce. Some time back, through the courtesy of Kew, I had some specimens, prepared on the Niger, analysed. The report was that it was worth 4*s.* to 4*s.* 6*d.* per lb. If prepared with care it might compete with Bengal. A large field here offers for development."

THE PITCH LAKE OF TRINIDAD.

A legislative order was passed some time ago in the West Indian island of Trinidad which may effect the commercial position of asphalt. The order raises the export duty on asphalt from 2*s.* to 5*s.* a ton, and the receipts from this source have been more than trebled in 1888. Most of the asphalt shipped is obtained from the Pitch Lake, which is the property of the Crown. The whole of the lake, with the exception of five acres, was from time to time between 1867 and February 1888 leased at almost nominal rates to private individuals or companies, but so long as the five-acre reserve was maintained no monopoly could be established. In November 1886 the Government gave notice that licences would be issued for the winning of pitch from this five-acre lot. The lessees, who, it appears, had formed some sort of coalition, ventured to dispute the right of the Government to grant such licences, but their appeal to the Privy Council was rejected. They thereupon adopted other means, and after much negotiation it was arranged that they should be granted a concession entitling them to the exclusive right of winning asphalt from the lake on payment of a royalty of 1*s.* 8*d.* and an export duty

of 5s. for every ton shipped, they on their part engaging to ship not less than 30,000 tons per annum. The minimum payment to be made by the concessionnaires is thus fixed at 10,000*l.* a year, which, as already stated, is very largely in excess of the annual income formerly derived from the Pitch Lake. The new arrangement is working very satisfactorily, and thus the colony has turned to profitable account a mine of wealth which has hitherto been regarded as little more than a natural curiosity and a show place for persons visiting the island.—*Chemist and Druggist*.

GATHERING SULPHUR FROM VOLCANO PITS.

The barque "Belle of Oregon" landed at Philadelphia a few days ago 300 tons of sulphur gathered from the extinct volcanoes in Japan. It is reported that the Japanese have recently found that the craters of some of the extinct volcanoes with which their islands abound are rich in sulphur. The ship "Cheesbrough" has been chartered to load a similar cargo at Hakodadi, Japan, for Sandy Hook, at seven dollars per ton.—*Engineering and Mining Journal*.

PRODUCTION OF SULPHUR IN ITALY IN 1888.

We are indebted to Mr. A. de Forester, Chargé d'Affaires of Italy, in Washington, for the following information concerning the sulphur production of Italy in 1888. It was furnished to this Legation by the Royal Ministry of Agriculture, Industry, and Commerce:—

—	Tons.	Lires.	Dollars.
District of Bologna....	19,254	1,554,825	= 310,385
" Sicily.....	322,042	21,512,405	= 4,302,481
" Naples	35,252	1,945,784	= 389,156
Total	376,538	25,013,014	= 5,002,602

—*Ibid.*

CHROMATES FROM NEW CALEDONIA.
